First novels. His writing during these prolific years was remarkably various and, except for his plays, resourceful. *Pickwick* began as high-spirited farce and contained many conventional comic butts and traditional jokes; like other early works, it was manifestly indebted to the contemporary theatre, the 18th-century English novelists, and a few foreign classics, notably *Don Quixote*. But, besides giving new life to old stereotypes, *Pickwick* displayed, if sometimes in embryo, many of the features that were to

be blended in varying proportions throughout his fiction: attacks, satirical or denunciatory, on social evils and inadequate institutions; topical references; an encyclopaedic knowledge of London (always his predominant fictional locale); pathos; a vein of the macabre; a delight in the demotic joys of Christmas; a pervasive spirit of benevolence and geniality; inexhaustible powers of character creation; a wonderful ear for characteristic speech, often imaginatively heightened; a strong narrative impulse; and a prose style that, if here overdependent on a few comic mannerisms, was highly individual and inventive. Rapidly improvised and written only weeks or days ahead of its serial publication, *Pickwick* contains weak and jejune passages and is an unsatisfactory whole—partly because Dickens was rapidly developing his craft as a novelist while writing and publishing it. What is remarkable is that a first novel, written in such circumstances, not only established him overnight and created a new tradition of popular literature but also survived, despite its crudities, as one of the best known novels in the world.

Popularity of *Pickwick Papers*

His self-assurance and artistic ambitiousness had appeared in *Oliver Twist,* where he rejected the temptation to repeat the successful *Pickwick* formula. Though containing much comedy still, *Oliver Twist* is more centrally concerned with social and moral evil (the workhouse and the criminal world); it culminates in Bill Sikes's murdering Nancy and Fagin's last night in the condemned cell at Newgate. The latter episode was memorably depicted in George Cruikshank's engraving; the imaginative potency of Dickens' characters and settings owes much, indeed, to his original illustrators (Cruikshank for *Sketches by "Boz"* and *Oliver Twist,* "Phiz" [Hablot K. Browne] for most of the other novels until the 1860s). The currency of his fiction owed much, too, to its being so easy to adapt into effective stage versions. Sometimes 20 London theatres simultaneously were producing adaptations of his latest story; so even nonreaders became acquainted with simplified versions of his works. The theatre was often a subject of his fiction, too, as in the Crummles troupe in *Nicholas Nickleby.* This novel reverted to the *Pickwick* shape and atmosphere, though the indictment of the brutal Yorkshire schools (Dotheboys Hall) continued the important innovation in English fiction seen in *Oliver Twist*—the spectacle of the lost or oppressed child as an occasion for pathos and social criticism. This was amplified in *The Old Curiosity Shop,* where the death of Little Nell was found overwhelmingly powerful at the time, though a few decades later it became a byword for "Victorian sentimentality." In *Barnaby Rudge* he attempted another genre, the historical novel. Like his later attempt in this kind, *A Tale of Two Cities,* it was set in the late 18th century and presented with great vigour and understanding (and some ambivalence of attitude) the spectacle of large-scale mob violence.

To create an artistic unity out of the wide range of moods and materials included in every novel, with often several complicated plots involving scores of characters, was made even more difficult by Dickens' writing and publishing them serially. In *Martin Chuzzlewit* he tried "to resist the temptation of the current Monthly Number, and to keep a steadier eye upon the general purpose and design" (1844 Preface). Its American episodes had, however, been unpremeditated (he suddenly decided to boost the disappointing sales by some America-baiting and to revenge himself against insults and injuries from the American press). A concentration on "the general purpose and design" was more effective in the next novel, *Dombey and Son* (1846–48), though the experience of writing the shorter, and unserialized, Christmas books had helped him obtain greater coherence.

A Christmas Carol (1843), suddenly conceived and written in a few weeks, was the first of these Christmas books (a new literary genre thus created incidentally). Tossed off while he was amply engaged in writing *Chuzzlewit,* it was an extraordinary achievement—the one great Christmas myth of modern literature. His view of life was later to be described or dismissed as "Christmas philosophy," and he himself spoke of "*Carol* philosophy" as the basis of a projected work. His "philosophy," never very elaborated, involved more than wanting the Christmas spirit to prevail throughout the year, but his great attachment to Christmas (in his family life as well as his writings) is indeed significant and has contributed to his popularity. "Dickens dead?" exclaimed a London costermonger's girl in 1870. "Then will Father Christmas die too?"—a tribute both to his association with Christmas and to the mythological status of the man as well as of his work. The *Carol* immediately entered the general consciousness; Thackeray, in a review, called it "a national benefit, and to every man and woman who reads it a personal kindness." Further Christmas books, essays, and stories followed annually (except in 1847) through 1867. None equalled the *Carol* in potency, though some achieved great immediate popularity. Cumulatively they represent a celebration of Christmas attempted by no other great author.

How he struck his contemporaries in these early years appears in R.H. Horne's *New Spirit of the Age* (1844). Dickens occupied the first and longest chapter, as

> . . . manifestly the product of his age . . . a genuine emanation from its aggregate and entire spirit. . . . He mixes extensively in society, and continually. Few public meetings in a benevolent cause are without him. He speaks effectively. . . . His influence upon his age is extensive—pleasurable, instructive, healthy, reformatory. . . .
>
> Mr. Dickens is, in private, very much what might be expected from his works. . . . His conversation is genial . . . [He] has singular personal activity, and is fond of games of practical skill. He is also a great walker, and very much given to dancing Sir Roger de Coverley. In private, the general impression of him is that of a first-rate practical intellect, with "no nonsense" about him.

Status as a public figure

He was indeed very much a public figure, actively and centrally involved in his world, and a man of confident presence. He was reckoned the best after-dinner speaker of the age; other superlatives he attracted included his having been the best shorthand reporter on the London press and his being the best amateur actor on the stage. Later he became one of the most successful periodical editors and the finest dramatic recitalist of the day. He was splendidly endowed with many skills. "Even irrespective of his literary genius," wrote an obituarist, "he was an able and strong-minded man, who would have succeeded in almost any profession to which he devoted himself" (*Times,* June 10, 1870). Few of his extraliterary skills and interests were irrelevant to the range and mode of his fiction.

Privately in these early years, he was both domestic and social. He loved home and family life and was a proud and efficient householder; he once contemplated writing a cookbook. To his many children, he was a devoted and delightful father, at least while they were young; relations with them proved less happy during their adolescence. Apart from periods in Italy (1844–45) and Switzerland and France (1846–47), he still lived in London, moving from an apartment in Furnival's Inn to larger houses as his income and family grew. Here he entertained his many friends, most of them popular authors, journalists, actors, or artists, though some came from the law and other professions or from commerce and a few from the aristocracy. Some friendships dating from his youth endured to the end, and, though often exasperated by the financial demands of his parents and other relatives, he was very fond of some of his family and loyal to most of the rest. Some literary squabbles came later, but he was on friendly terms with most of his fellow authors, of the older generation as well as his own. Necessarily solitary while writing and during the long walks (especially through the streets at night) that became essential to his creative processes, he was generally social at other times. He enjoyed society that was unpretentious and conversation that was genial and sensible but not too intellectualized or exclusively literary. High society he generally avoided, after a few early incursions into the great houses; he hated to be lionized or patronized.

He had about him "a sort of swell and overflow as of a prodigality of life," an American journalist said. Everyone was struck by the brilliance of his eyes and his smart, even dandyish, appearance ("I have the fondness of a savage for finery," he confessed). John Forster, his intimate friend and future biographer, recalled him at the *Pickwick* period:

> the quickness, keenness, and practical power, the eager, restless, energetic outlook on each several feature [of his face] seemed to tell so little of a student or writer of books, and so much of a man of action and business in the world. Light and motion flashed from every part of it.

He was proud of his art and devoted to improving it and using it to good ends (his works would show, he wrote, that "Cheap Literature is not behind-hand with the Age, but holds its place, and strives to do its duty"), but his art never engaged all his formidable energies. He had no desire to be narrowly literary.

Unsuccessful journalistic ventures

A notable, though unsuccessful, demonstration of this was his being founder-editor in 1846 of the *Daily News* (soon to become the leading Liberal newspaper). His journalistic origins, his political convictions and readiness to act as a leader of opinion, and his wish to secure a steady income independent of his literary creativity and of any shifts in novel readers' tastes made him attempt or plan several periodical ventures in the 1840s. The return to daily journalism soon proved a mistake—the biggest fiasco in a career that included few such misdirections or failures. A more limited but happier exercise of his practical talents began soon afterward: for more than a decade he directed, energetically and with great insight and compassion, a reformatory home for young female delinquents, financed by his wealthy friend Angela Burdett-Coutts. The benevolent spirit apparent in his writings often found practical expression in his public speeches, fund-raising activities, and private acts of charity.

Dombey and Son (1846–48) was a crucial novel in his development, a product of more thorough planning and maturer thought and the first in which "a pervasive uneasiness about contemporary society takes the place of an intermittent concern with specific social wrongs" (Kathleen Tillotson). Using railways prominently and effectively, it was very up-to-date, though the questions posed included such perennial moral and religious challenges as are suggested by the child Paul's first words in the story: "Papa, what's money?" Some of the corruptions of money and pride of place and the limitations of "respectable" values are explored, virtue and human decency being discovered most often (as elsewhere in Dickens) among the poor, humble, and simple. In Paul's early death Dickens offered another famous pathetic episode; in Mr. Dombey he made a more ambitious attempt than before at serious and internal characterization. *David Copperfield* (1849–50) has been described as a "holiday" from these larger social concerns and most notable for its childhood chapters, "an enchanting vein which he had never quite found before and which he was never to find again" (Edmund Wilson). Largely for this reason and for its autobiographical interest, it has always been among his most popular novels and was Dickens' own "favourite child." It incorporates material from the autobiography he had recently begun but soon abandoned and is written in the first person, a new technique for him. David differs from his creator in many ways, however, though Dickens uses many early experiences that had meant much to him—his period of work in the factory while his father was jailed, his schooling and reading, his passion for Maria Beadnell, and (more cursorily) his emergence from parliamentary reporting into successful novel writing. In Micawber the novel presents one of the "Dickens characters" whose imaginative potency extends far beyond the narratives in which they figure; Pickwick and Sam Weller, Mrs. Gamp and Mr. Pecksniff, and Scrooge are some others.

Autobiographical interest of *David Copperfield*

MIDDLE YEARS

Journalism. Dickens' journalistic ambitions at last found a permanent form in *Household Words* (1850–59) and its successor, *All the Year Round* (1859–88). Popular weekly miscellanies of fiction, poetry, and essays on a wide range of topics, these had substantial and increasing circulations, reaching 300,000 for some of the Christmas numbers. Dickens contributed some serials—the lamentable *Child's History of England* (1851–53), *Hard Times* (1854), *A Tale of Two Cities* (1859), and *Great Expectations* (1860–61)—and essays, some of which were collected in *Reprinted Pieces* (1858) and *The Uncommercial Traveller* (1861, later amplified). Particularly in 1850–52 and during the Crimean War, he contributed many items on current political and social affairs; in later years he wrote less—much less on politics—and the magazine was less political, too. Other distinguished novelists contributed serials, including Mrs. Gaskell, Wilkie Collins, Charles Reade, and Bulwer Lytton. The poetry was uniformly feeble; Dickens was imperceptive here. The reportage, often solidly based, was bright (sometimes painfully so) in manner. His conduct of these weeklies shows his many skills as editor and journalist but also some limitations in his tastes and intellectual ambitions. The contents are revealing in relation to his novels: he took responsibility for all the opinions expressed (for articles were anonymous) and selected and amended contributions accordingly; thus comments on topical events and so on may generally be taken as representing his opinions, whether or not he wrote them. No English author of comparable status has devoted 20 years of his maturity to such unremitting editorial work, and the weeklies' success was due not only to his illustrious name but also to his practical sagacity and sustained industry. Even in his creative work, as his eldest son said,

> No city clerk was ever more methodical or orderly than he; no humdrum, monotonous, conventional task could ever have been discharged with more punctuality, or with more businesslike regularity.

Novels. The novels of these years, *Bleak House* (1852–53), *Hard Times* (1854), and *Little Dorrit* (1855–57), were much "darker" than their predecessors. Presenting a remarkably inclusive and increasingly sombre picture of contemporary society, they were inevitably often seen at the time as fictionalized propaganda about ephemeral issues. They are much more than this, though it is never easy to state how Dickens' imagination transforms their many topicalities into an artistically coherent vision that transcends their immediate historical context. Similar questions are raised by his often basing fictional characters, places, and institutions on actual originals. He once spoke of his mind's taking "a fanciful photograph" of a scene, and there is a continual interplay between photographic realism and "fancy" (or imagination). "He describes London like a special correspondent for posterity" (Walter Bagehot, 1858), and posterity has certainly found in his fiction the response of an acute, knowledgeable, and concerned observer to the social and political developments of "the moving age." In the novels of the 1850s, he is politically more despondent, emotionally more tragic. The satire is harsher, the humour less genial and abundant, the "happy endings" more subdued than in the early fiction. Technically, the later novels are more coherent, plots being more fully related to themes, and themes being often expressed through a more insistent use of imagery and symbols (grim symbols, too, such as the fog in *Bleak House* or the prison in *Little Dorrit*). His art here is more akin to poetry than to what is suggested by the photographic or journalistic comparisons. "Dickensian" characterization continues in the sharply defined and simplified grotesque or comic figures, such as Chadband in *Bleak House* or Mrs. Sparsit in *Hard Times*, but large-scale figures of this type are less frequent (the Gamps and Micawbers belong to the first half of his career). Characterization also has become more subordinate to "the general purpose and design"; moreover, Dickens is presenting characters of greater complexity, who provoke more complex responses in the reader (William Dorrit, for instance). Even the juvenile leads, who had usually been thinly conceived conventional figures, are now often more complicated in their make-up and less easily rewarded by good fortune. With his secular hopes diminishing, Dickens becomes more concerned with "the great final secret of all life"—a phrase from *Little Dorrit*, where the spiritual dimension of his work is most overt. Critics disagree as to how far so worldly a novelist succeeds artistically in enlarging his view to include the religious. These novels, too, being manifestly an ambitious attempt to explore the prospects of humanity at this time, raise questions, still much debated, about the intelligence and profundity of his understanding of society.

Themes of the later novels

Personal unhappiness. Dickens' spirits and confidence

in the future had indeed declined: 1855 was "a year of much unsettled discontent for him," his friend Forster recalled, partly for political reasons (or, as Forster hints, his political indignation was exacerbated by a "discontent" that had personal origins). The Crimean War, besides exposing governmental inefficiency, was distracting attention from the "poverty, hunger, and ignorant desperation" at home. In *Little Dorrit*, "I have been blowing off a little of indignant steam which would otherwise blow me up . . . ," he wrote, "but I have no present political faith or hope—not a grain." Not only were the present government and Parliament contemptible but "representative government is become altogether a failure with us, . . . the whole thing has broken down . . . and has no hope in it." Nor had he a coherent alternative to suggest. This desperation coincided with an acute state of personal unhappiness. The brief tragicomedy of Maria Beadnell's reentry into his life, in 1855, finally destroyed one nostalgic illusion and also betrayed a perilous emotional immaturity and hunger. He now openly identified himself with some of the sorrows dramatized in the adult David Copperfield:

> Why is it, that as with poor David, a sense comes always crushing on me, now, when I fall into low spirits, as of one happiness I have missed in life, and one friend and companion I have never made?

Marital grief

This comes from the correspondence with Forster in 1854–55, which contains the first admissions of his marital unhappiness; by 1856 he is writing, "I find the skeleton in my domestic closet is becoming a pretty big one"; by 1857–58, as Forster remarks, an "unsettled feeling" had become almost habitual with him, "and the satisfactions which home should have supplied, and which indeed were essential requirements of his nature, he had failed to find in his home." From May 1858, Catherine Dickens lived apart from him. A painful scandal arose, and Dickens did not act at this time with tact, patience, or consideration. The affair disrupted some of his friendships and narrowed his social circle, but surprisingly it seems not to have damaged his popularity with the public.

Catherine Dickens maintained a dignified silence, and most of Dickens' family and friends, including his official biographer, Forster, were discreetly reticent about the separation. Not until 1939 did one of his children (Katey), speaking posthumously through conversations recorded by a friend, offer a candid inside account. It was discreditable to him, and his self-justifying letters must be viewed with caution. He there dated the unhappiness of his marriage back to 1838, attributed to his wife various "peculiarities" of temperament (including her sometimes labouring under "a mental disorder"), emphatically agreed with her (alleged) statement that "she felt herself unfit for the life she had to lead as my wife," and maintained that she never cared for the children nor they for her. In more temperate letters, where he acknowledged her "amiable and complying" qualities, he simply and more acceptably asserted that their temperaments were utterly incompatible. She was, apparently, pleasant but rather limited; such faults as she had were rather negative than positive, though family tradition from a household that knew the Dickenses well speaks of her as "a whiney woman" and as having little understanding of, or patience with, the artistic temperament.

Friendship with Ellen Ternan

Dickens' self-justifying letters lack candour in omitting to mention Ellen Ternan, an actress 27 years his junior, his passion for whom had precipitated the separation. Two months earlier he had written more frankly to an intimate friend:

> The domestic unhappiness remains so strong upon me that I can't write, and (waking) can't rest, one minute. I have never known a moment's peace or content, since the last night of The Frozen Deep.

The Frozen Deep was a play in which he and Nelly (as Ellen was called) had performed together in August 1857. She was an intelligent girl, of an old theatrical family; reports speak of her as having "a pretty face and well-developed figure"—or "passably pretty and not much of an actress." She left the stage in 1860; after Dickens' death she married a clergyman and helped him run a school. The affair was hushed up until the 1930s, and evidence about it remains scanty, but every addition confirms that Dickens was deeply attached to her and that their relationship lasted until his death. It seems likely that she became his mistress, though probably not until the 1860s; assertions that a child, or children, resulted remain unproved. Similarly, suggestions that the anguish experienced by some of the lovers in the later novels may reflect Dickens' own feelings remain speculative. It is tempting, indeed, to associate Nelly with some of their heroines (who are more spirited and complex, less of the "legless angel," than most of their predecessors), especially as her given names, Ellen Lawless. seem to be echoed by those of heroines in the three final novels—Estella, Bella, and Helena Landless—but nothing definite is known about how she responded to Dickens, what she felt for him at the time, or how close any of these later love stories were to aspects or phases of their relationship.

"There is nothing very remarkable in the story," commented one early transmitter of it, and this seems just. Many middle-aged men feel an itch to renew their emotional lives with a pretty young girl, even if, unlike Dickens, they cannot plead indulgence for "the wayward and unsettled feeling which is part (I suppose) of the tenure on which one holds an imaginative life." But the eventual disclosure of this episode caused surprise, shock, or piquant satisfaction, being related of a man whose rebelliousness against his society had seemed to take only impeccably reformist shapes. A critic in 1851, listing the reasons for his unique popularity, had cited "above all, his deep reverence for the household sanctities, his enthusiastic worship of the household gods." After these disclosures he was, disconcertingly or intriguingly, a more complex man; and, partly as a consequence, Dickens the novelist also began to be seen as more complex, less conventional, than had been realized. The stimulus was important, though Nelly's significance, biographically and critically, has proved far from inexhaustible.

Public readings. In the longer term, Kathleen Tillotson's remark is more suggestive: "his lifelong love-affair with his reading public, when all is said, is by far the most interesting love-affair of his life." This took a new form, about the time of Dickens' separation from his wife, in his giving public readings from his works, and it is significant that, when trying to justify this enterprise as certain to succeed, he referred to "that particular relation (personally affectionate and like no other man's) which subsists between me and the public." The remark suggests how much Dickens valued his public's affection, not only as a stimulus to his creativity and a condition for his commercial success but also as a substitute for the love he could not find at home. He had been toying with the idea of turning paid reader since 1853, when he began giving occasional readings in aid of charity. The paid series began in April 1858, the immediate impulse being to find some energetic distraction from his marital unhappiness. But the readings drew on more permanent elements in him and his art: his remarkable histrionic talents, his love of theatricals and of seeing and delighting an audience, and the eminently performable nature of his fiction. Moreover, he could earn more by reading than by writing, and more certainly; it was easier to force himself to repeat a performance than create a book.

Histrionic talents

His initial repertoire consisted entirely of Christmas books but was soon amplified by episodes from the novels and magazine Christmas stories. A performance usually consisted of two items; of the 16 eventually performed, the most popular were "The Trial from *Pickwick*" and the *Carol*. Comedy predominated, though pathos was important in the repertoire, and horrifics were startlingly introduced in the last reading he devised, "Sikes and Nancy," with which he petrified his audiences and half killed himself. Intermittently, until shortly before his death, he gave seasons of readings in London and embarked upon hard-working tours through the provinces and (in 1867–68) the United States. Altogether he performed about 471 times. He was a magnificent performer, and important elements in his art—the oral and dramatic qualities—were demonstrated in these renderings. His insight and skill revealed nuances in the narration and characterization that few

readers had noticed. Necessarily, such extracts or short stories, suitable for a two-hour entertainment, excluded some of his larger and deeper effects—notably, his social criticism and analysis—and his later novels were underrepresented. Dickens never mentions these inadequacies. He manifestly enjoyed the experience until, near the end, he was becoming ill and exhausted. He was writing much less in the 1860s. It is debatable how far this was because the readings exhausted his energies, while providing the income, creative satisfaction, and continuous contact with an audience that he had formerly obtained through the novels. He gloried in his audiences' admiration and love. Some friends thought this too crude a gratification, too easy a triumph, and a sad declension into a lesser and ephemeral art. In whatever way the episode is judged, it was characteristic of him—of his relationship with his public, his business sense, his stamina, his ostentatious display of supplementary skills, and also of his originality. No important author (at least, according to reviewers, since Homer) and no English author since who has had anything like his stature has devoted so much time and energy to this activity. The only comparable figure is his contemporary, Mark Twain, who acknowledged Dickens as the pioneer.

LAST YEARS

Final novels. Tired and ailing though he was, he remained inventive and adventurous in his final novels. *A Tale of Two Cities* (1859) was an experiment, relying less than before on characterization, dialogue, and humour. An exciting and compact narrative, it lacks too many of his strengths to count among his major works. Sydney Carton's self-sacrifice was found deeply moving by Dickens and by many readers; Dr. Manette now seems a more impressive achievement in serious characterization. The French Revolution scenes are vivid, if superficial in historical understanding. *Great Expectations* (1860–61) resembles *Copperfield* in being a first-person narration and in drawing on parts of Dickens' personality and experience. Compact like its predecessor, it lacks the panoramic inclusiveness of *Bleak House, Little Dorrit,* and *Our Mutual Friend,* but, though not his most ambitious, it is his most finely achieved novel. The hero Pip's mind is explored with great subtlety, and his development through a childhood and youth beset with hard tests of character is traced critically but sympathetically. Various "great expectations" in the book proved ill founded—a comment as much on the values of the age as on the characters' weaknesses and misfortunes. *Our Mutual Friend* (1864–65), a large inclusive novel, continues this critique of monetary and class values. London is now grimmer than ever before, and the corruption, complacency, and superficiality of "respectable" society are fiercely attacked. Many new elements are introduced into Dickens' fictional world, but his handling of the old comic-eccentrics (such as Boffin, Wegg, and Venus) is sometimes tiresomely mechanical. How the unfinished *Edwin Drood* (1870) would have developed is uncertain. Here again Dickens left panoramic fiction to concentrate on a limited private action. The central figure was evidently to be John Jasper, whose eminent respectability as a cathedral organist was in extreme contrast to his haunting low opium dens and, out of violent sexual jealousy, murdering his nephew. It would have been his most elaborate treatment of the themes of crime, evil, and psychological abnormality that had recurred throughout his novels; a great celebrator of life, he was also obsessed with death.

Change in Dickens' personality

How greatly Dickens personally had changed appears in remarks by friends who met him again, after many years, during the American reading tour in 1867–68. "I sometimes think . . . ," wrote one, "I must have known two individuals bearing the same name, at various periods of my own life." But just as the fiction, despite many developments, still contained many stylistic and narrative features continuous with the earlier work, so, too, the man remained a "human hurricane," though he had aged considerably, his health had deteriorated, and his nerves had been jangled by travelling ever since his being in a railway accident in 1865. Other Americans noted that, though grizzled, he was "as quick and elastic in his movements as ever." His photographs, wrote a journalist after one of the readings, "give no idea of his genial expression. To us he appears like a hearty, companionable man, with a deal of fun in him." But that very day Dickens was writing, "I am nearly used up," and listing the afflictions now "telling heavily upon me." His pride and the old-trouper tradition made him conceal his sufferings. And, if sometimes by an effort of will, his old high spirits were often on display. "The cheerfullest man of his age," he was called by his American publisher, J.T. Fields; Fields's wife more perceptively noted, "Wonderful, the flow of spirits C.D. has for a sad man."

His fame remained undiminished, though critical opinion was increasingly hostile to him. Henry Wadsworth Longfellow, noting the immense enthusiasm for him during the American tour, remarked: "One can hardly take in the whole truth about it, and feel the universality of his fame." But in many respects he was "a sad man" in these later years. He never was tranquil or relaxed. Various old friends were now estranged or dead or for other reasons less available; he was now leading a less social life and spending more time with young friends of a calibre inferior to his former circle. His sons were causing much worry and disappointment; "all his fame goes for nothing," said a friend, "since he has not the one thing. He is very unhappy in his children." His life was not all dreary, however. He loved his country house, Gad's Hill, and he could still "warm the social atmosphere wherever he appeared with that summer glow which seemed to attend him." T.A. Trollope (contributor to Dickens' *All the Year Round* and brother of the novelist Anthony Trollope), who wrote that, despaired of giving people who had not met him any idea of

> the general charm of his manner. . . . His laugh was brimful of enjoyment. . . . His enthusiasm was boundless. . . . He was a *hearty* man, a large-hearted man, . . . a strikingly manly man.

Final months

Farewell readings. His health remained precarious after the punishing American tour and was further impaired by his addiction to giving the strenuous "Sikes and Nancy" reading. His farewell reading tour was abandoned when, in April 1869, he collapsed. He began writing another novel and gave a short farewell season of readings in London, ending with the famous speech, "From these garish lights I vanish now for evermore . . ."—words repeated, less than three months later, on his funeral card. He died suddenly at Gad's Hill on June 9, 1870, and was buried in Westminster Abbey.

ASSESSMENT

Contemporary opinion. Ralph Waldo Emerson, attending one of Dickens' readings in Boston, "laughed as if he must crumble to pieces," but, discussing Dickens afterward, he said:

> I am afraid he has too much talent for his genius; it is a fearful locomotive to which he is bound and can never be free from it nor set to rest. . . . He daunts me! I have not the key.

There is no simple key to so prolific and multifarious an artist nor to the complexities of the man, and interpretation of both is made harder by his possessing and feeling the need to exercise so many talents besides his imagination. How his fiction is related to these talents—practical, journalistic, oratorical, histrionic—remains controversial. Also the geniality and unequalled comedy of the novels must be related to the sufferings, errors, and self-pity of their author and to his concern both for social evils and for the perennial griefs and limitations of humanity. The novels cover a wide range, social, moral, emotional, and psychological. Thus, he is much concerned with very ordinary people but also with abnormality (*e.g.*, eccentricity, depravity, madness, hallucinations, dream states). He is both the most imaginative and fantastic and the most topical and documentary of great novelists. He is unequal, too; a wonderfully inventive and poetic writer, he can also, even in his mature novels, write with a painfully slack conventionality.

Biographers have only since the mid-20th century known enough to explore the complexity of Dickens' nature. Critics have always been challenged by his art, though

Most popular novels

from the start it contained enough easily acceptable ingredients, evident skill and gusto, to ensure popularity. The earlier novels were and by and large have continued to be Dickens' most popular works: *The Pickwick Papers, Oliver Twist, Martin Chuzzlewit, A Christmas Carol,* and *David Copperfield.* Critics began to demur against the later novels, deploring the loss of the freer comic spirit, baffled by the more symbolic mode of his art, and uneasy when the simpler reformism over isolated issues became a more radical questioning of social assumptions and institutions. Dickens was never neglected or forgotten and never lost his popularity, but for 70 years after his death he received remarkably little serious attention (George Gissing, G.K. Chesterton, and George Bernard Shaw being notable exceptions). F.R. Leavis, later to revise his opinion, was speaking for many, in 1948, when he asserted that "the adult mind doesn't as a rule find in Dickens a challenge to an unusual and sustained seriousness"; Dickens was indeed a great genius, "but the genius was that of a great entertainer."

Modern criticism. Modern Dickens criticism dates from 1940–41, with the very different impulses given by George Orwell, Edmund Wilson, and Humphry House. In the 1950s, a substantial reassessment and re-editing of the works began, his finest artistry and greatest depth now being discovered in the later novels—*Bleak House, Little Dorrit,* and *Great Expectations*—and (less unanimously) in *Hard Times* and *Our Mutual Friend.* Scholars have explored his working methods, his relations with his public, and the ways in which he was simultaneously an eminently Victorian figure and an author "not of an age but for all time." Biographically, little had been added to Forster's massive and intelligent *Life* (1872–74), except the Ellen Ternan story, until Edgar Johnson's in 1952. Since then, no radically new view has emerged, though several works—including those by Joseph Gold (1972) and Fred Kaplan (1975)—have given particular phases or aspects fuller attention. The centenary in 1970 demonstrated a critical consensus about his standing second only to William Shakespeare in English literature, which would have seemed incredible 40 or even 20 years earlier.

MAJOR WORKS

NOVELS: *The Pickwick Papers* (1837); *Oliver Twist* (1838); *Nicholas Nickleby* (1839); *The Old Curiosity Shop* and *Barnaby Rudge* (1841), two novels first published in a "clock framework," later abandoned, under the title of *Master Humphrey's Clock; Martin Chuzzlewit* (1844); *Dombey and Son* (1848); *David Copperfield* (1850); *Bleak House* (1853); *Hard Times* (1854); *Little Dorrit* (1857); *A Tale of Two Cities* (1859); *Great Expectations* (1861); *Our Mutual Friend* (1865); *The Mystery of Edwin Drood* (1870, unfinished).

CHRISTMAS BOOKS: *A Christmas Carol* (1843); *The Chimes* (1845, for 1844); *The Cricket on the Hearth* (1846, for 1845); *The Battle of Life* (1846); *The Haunted Man* (1848).

STORIES (CHRISTMAS STORIES): The volume entitled *Christmas Stories* in collected editions includes "A Christmas Tree" (1850); "What Christmas Is as We Grow Older" (1851); "The Poor Relation's Story" (1852); "Nobody's Story" (1853); "The Seven Poor Travellers" (1854); "The Holly-Tree," sometimes called "The Holly-Tree Inn" (1855); "The Wreck of the Golden Mary" (1856); "The Perils of Certain English Prisoners" (1857); "Going into Society" (1858); "The Haunted House" (1859); "A Message from the Sea" (1860); "Tom Tiddler's Ground" (1861); "Somebody's Luggage" (1862); "Mrs. Lirriper's Lodgings" (1863); "Mrs. Lirriper's Legacy" (1864); "Doctor Marigold" (1865); "Mugby Junction" (1866); "No Thoroughfare" (1867). (OTHER STORIES): in collected editions generally appended to the volume entitled *Reprinted Pieces,* ["The Lamplighter" (1841);] "To Be Read at Dusk" (1852); "Hunted Down" (1859); "George Silverman's Explanation" (1867); "Holiday Romance" (1868; children's story in 4 parts; pt. 2, "The Magic Fishbone," often reprinted separately).

OTHER WORKS: *Sketches by "Boz,"* 2 series (1836, together, 1839, included Dickens' first published work, "A Dinner at Poplar Walk," 1833); *Sketches of Young Gentlemen* (1838) and *Sketches of Young Couples* (1840), both usually appended to the *Sketches by "Boz"* volume, in collected editions, which also usually contains "The Mudfog Papers" (contributed to *Bentley's Miscellany,* 1837–38); *American Notes* (1842); *Pictures from Italy* (1846); *The Life of Our Lord* (completed 1849, for his children; published 1934); *A Child's History of England* (1852–54); "The Lazy Tour of Two Idle Apprentices" (with Wilkie Collins, contributed to *Household Words* [1857]; often included in the volume entitled *Christmas Stories*); *Reprinted Pieces* (1858; contributed to *Household Words,* 1850–56); *The Uncommercial Traveller* (1861, amplified 1868, 1875; contributed to *All the Year Round,* 1860–69); *Plays and Poems,* ed. by R.H. Shepherd (1885); *Miscellaneous Papers,* ed. by B.W. Matz (1908; the most substantial posthumous collection, mainly essays contributed to *Household Words,* 1850–59; 16 further items, in the volume retitled *Collected Papers,* in *The Nonesuch Dickens,* 1937); *Uncollected Writings from Household Words 1850–1859,* ed. by Harry Stone (1968).

BIBLIOGRAPHY

Bibliographies: K.J. FIELDING, *Charles Dickens* (1953); ADA NISBET, "Charles Dickens," in LIONEL STEVENSON (ed.), *Victorian Fiction: A Guide to Research,* pp. 44–153 (1964, reprinted 1980), a full discussion of materials for Dickens studies and of writings about him in many languages, through 1962; *Victorian Fiction: A Second Guide to Research,* ed. by GEORGE H. FORD, pp. 34–113 (1978), covering 1963–74. Digestion and Digestive Systems

In order to sustain themselves, all organisms must obtain nutrients from the environment. Some nutrients serve as raw materials for the synthesis of cellular material; others (*e.g.*, many vitamins) act as regulators of chemical reactions in living cells; and still others, upon oxidation in living cells, yield energy. Not all nutrients, however, are in a form suitable for immediate use by an organism; some must undergo physical and chemical changes before they can serve as energy or cell substance.

This article begins with an overview of digestion and digestive systems, referring to specific organisms to clarify the account; in the latter part, it emphasizes aspects of the human digestive system, its functions, and related diseases and disorders.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, Part Four, Division II, especially Section 421.

The article is divided into the following sections:

General features of the digestive process

Through the act of eating, or ingestion, nutrients are taken from the environment. Many nutrient molecules are so large and complex that they must be split into smaller molecules before they can be used by the organism. This process of breaking down food into molecular particles of usable size and content is called digestion. Unusable components are expelled from the organism by a process called egestion, or excretion. Some plants, many microorganisms, and all animals perform these three functions—ingestion, digestion, and egestion (often grouped under the term alimentation)—but, as expected, the details differ considerably from group to group.

Autotrophy and heterotrophy

The problems associated with nutrient intake and processing differ greatly depending on whether the organism is autotrophic or heterotrophic. Autotrophic organisms are those that can manufacture the large energy-rich organic compounds necessary for life from simple inorganic raw materials; consequently, they require only simple nutrients from the environment. By contrast, heterotrophic organisms cannot manufacture complex organic compounds from simple inorganic ones, and so they must obtain preformed organic molecules directly from the environment.

Green plants constitute by far the majority of the Earth's autotrophic organisms. During the process of photosynthesis, they use light energy to synthesize organic materials from carbon dioxide and water. Both compounds can be absorbed easily across the membranes of cells—in a typical land plant, carbon dioxide is absorbed from the air by leaf cells, and water is absorbed from the soil by root cells—and used directly in photosynthesis; *i.e.*, neither of them requires digestion. The only other nutrients needed by most green plants are minerals such as nitrogen, phosphorus, and potassium, which also can be absorbed directly and require no digestion. There are, however, a few green plants (*e.g.*, sundew, Venus's-flytrap, pitcher plant) that supplement their inorganic diet with organic compounds (particularly protein) obtained by trapping and digesting insects and other small animals.

Heterotrophy characterizes all animals, most microorganisms, and plants and plantlike organisms (*e.g.*, fungi) that lack the pigment chlorophyll, which is necessary for photosynthesis. These organisms must ingest organic nutrients—carbohydrates, proteins, and lipids (fats)—and, by digestion, rearrange them into a form suitable for their own particular needs.

INGESTION

As already explained, the nutrients procured by most green plants are small inorganic molecules that can move with relative ease across cell membranes. Heterotrophic organisms such as bacteria and fungi, which require organic nutrients yet lack adaptations for ingesting bulk food, also

rely on direct absorption of small nutrient molecules across cell membranes; molecules of carbohydrates, proteins, or lipids, however, are too large and complex to move easily across cell membranes. Bacteria and fungi circumvent this by secreting digestive enzymes onto the food material; these enzymes catalyze the splitting of the large molecules into smaller units that are then absorbed into the cells. In other words, the bacteria and fungi perform extracellular digestion—digestion outside cells—before ingesting the food. This is often referred to as osmotrophic nutrition.

Ingestion by simple cells

Like bacteria, protozoans are unicellular organisms, but their method of feeding is quite different. They ingest relatively large particles of food and carry out intracellular digestion (digestion inside cells) through a method of feeding called phagotrophic nutrition. To a lesser degree many protozoans also are osmotrophic. Some organisms (*e.g., Amoeba*) put out pseudopodia ("false feet"), which flow around the food particle until it is completely enclosed in a membrane-bounded chamber called a food vacuole; this process (Figure 1A) is called phagocytosis. Other protozoans (*e.g., Paramecium*) pinch off food vacuoles from the end of a prominent oral groove into which food particles are drawn by the beating of numerous small, hairlike projections (cilia). In still other cases of phagotrophic nutrition, tiny particles of food adhere to the membranous surface of the cell, which then folds inward and is pinched off as a vacuole; this process (Figure 1B) is called pinocytosis. The food particles contained in vacuoles formed through phagocytosis or pinocytosis have not entered the cell in the fullest sense until they are digested into molecules able to cross the membrane of the vacuole and become incorporated into the cellular substance.

Most multicellular animals possess some sort of digestive cavity—a chamber opening to the exterior via a mouth—in which digestion takes place. Large particles of food are broken down to units of more manageable size within the cavity before being taken into cells and reassembled (or assimilated) as cellular substance.

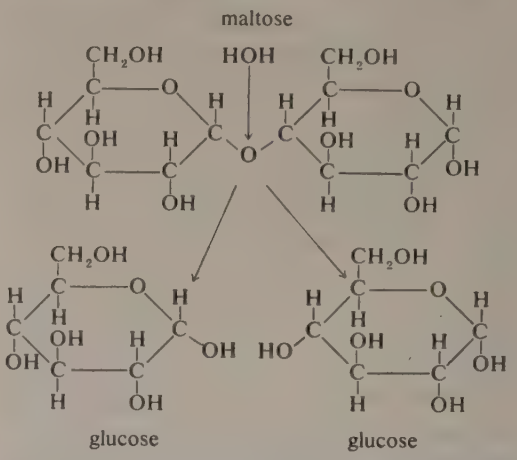
DIGESTION

The enzymatic splitting of large and complex molecules into smaller ones is effective only if the enzyme molecules come into direct contact with the molecules of the material they are to digest. In animals that ingest very large pieces of food, only the molecules at the surface are exposed to the digestive enzymes. Digestion can proceed more efficiently, therefore, if the bulk food is first mechanically broken down, exposing more molecules for digestion. Among the variety of devices that have evolved to perform such mechanical processing of food are the chewing teeth of mammals and the muscular gizzards of birds.

The chemical basis of digestion

The chemical reactions involved in digestion can be clarified by an account of the digestion of maltose sugar. Maltose is, technically, a double sugar, since it is composed of two molecules of the simple sugar glucose bonded together. The digestive enzyme maltase catalyzes a reaction in which a molecule of water is inserted at the point at which the two glucose units are linked, thereby disconnecting them, as illustrated below.



In chemical terms, the maltose has been hydrolyzed. All digestive enzymes act in a similar way and thus are hydrolyzing enzymes.

Many other nutrient molecules are much more complex, being polymers, or long chains of simple component units. Starch, for example, is a carbohydrate, like maltose, but its molecules are composed of thousands of glucose units bonded together. Even so, the digestion of starch is essentially the same as the digestion of maltose: each linkage between adjacent glucose units is hydrolyzed, with the result that the starch molecule is split into thousands of glucose molecules. Protein molecules also are polymers, but their constituent units are amino acids instead of simple sugars. Proteolytic (*i.e.,* protein-digesting) enzymes split the protein chains by hydrolyzing the bonds between adjacent amino acids. Because as many as 20 different kinds of amino acids may act as building blocks for proteins, the complete digestion of a protein into its amino acids requires the concerted action of several different proteolytic enzymes, each capable of hydrolyzing the bonds between particular pairs of amino acids. Fat molecules, too, are composed of smaller building-block units (the alcohol glycerol plus three fatty acid groups); they are hydrolyzed by the enzyme lipase.

Various other classes of compounds are digested by hydrolytic enzymes specific for them. Not all of these enzymes occur in every organism; for example, few animals possess cellulase (cellulose-digesting enzyme), despite the fact that cellulose constitutes much of the total bulk of the food ingested by plant-eating animals. Some nonetheless benefit from the cellulose in their diet because their digestive tracts contain microorganisms (known as symbionts) capable of digesting cellulose; the herbivores absorb some of the products of their symbionts' digestive activity.

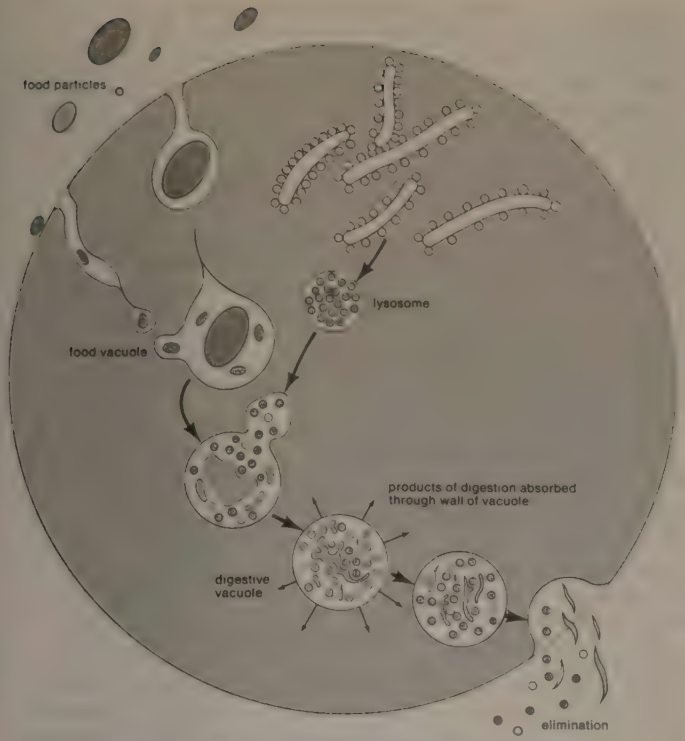


Figure 2: *The role of lysosomes in intracellular digestion.* Digestion takes place when a food vacuole and a lysosome unite, forming a digestive vacuole. The products of digestion are absorbed across the vacuolar membrane, and the indigestible wastes are ultimately expelled to the outside.

Adapted from W.T. Keeton, *Biological Science*, © 1967 by W W. Norton & Company, Inc.

So far, emphasis has been placed on digestion's role in converting large complex molecules into smaller simpler ones that can move across membranes, thus permitting absorption of food into cells. The same processes occur when substances must be moved from cell to cell within a multicellular organism. Thus green plants, which do not have to digest incoming nutrients, digest stored material, such as starch, before it can be transported from storage organs (tubers, bulbs, corms) to points of utilization, such as growing buds.

EGESTION

The elimination of indigestible matter

Animals that ingest bulk food unavoidably take in some matter that they are incapable of using; for example, since man lacks cellulase, the cellulose he ingests in vegetables and fruits is indigestible. It cannot be absorbed from the digestive tract, and the residue that is not broken down by bacteria must be expelled from the body.

In the case of unicellular organisms that form food vacuoles, the vacuoles eventually fuse with the cell membrane and then rupture, releasing indigestible wastes to the outside (Figure 2). Animals periodically release such waste from their digestive tracts either by regurgitating it through the mouth or by eliminating it as feces through the anus.

Fecal constituents in species with an alimentary canal also include cast-off effete (damaged or worn-out) cells from the living mucous membrane (mucosa) and, in higher animals, bacteria that exist in the intestine in a symbiotic relationship. In the higher animals, the life span of a cell from the mucosal epithelium is four to eight days, and the life span of the specialized cells, such as the acid-secreting parietal cells located in the stomach, is one to three years.

Invertebrate digestive systems

COMPARISON OF UNICELLULAR AND MULTICELLULAR ORGANISMS

Vacuolar systems. Unicellular organisms that ingest food particles via vacuoles rely on intracellular digestion to prepare the nutrients for use. The enzymes that catalyze this digestion, being very potent chemicals capable of breaking down the cell substance itself, are held until needed in special packets, or vesicles, called lysosomes; the membrane of a lysosome is both impermeable to the enzymes and capable of resisting their hydrolytic action. Soon after a food vacuole is formed, a lysosome fuses with it (Figure 2). Food material and digestive enzymes are mixed in the resulting composite vesicle, which is sometimes called a digestive vacuole. This vacuole moves in an orderly fashion through the cell, during which passage the products of digestion are absorbed, leaving the indigestible material, which is eventually expelled.

Vacuolar digestion is not restricted to unicellular organisms. Many multicellular invertebrates partly digest their food extracellularly before phagocytizing the remainder, which is then digested by the process described above.

Channel-network system. The sponges, among the simplest multicellular organisms, have what amounts to diversionary water channels that serve to bring water and food to their component cells. The channels are lined with special cells bearing whiplike structures called flagella that create water currents. A steady flow of water inward through smaller secondary channels and then out the main, or excurrent, canal carries with it bits of food. The lining cells capture the food particles and enclose them in food vacuoles, wherein the matter is digested as in protozoans—by intracellular means.

EVOLUTION OF CELLULAR SPECIALIZATION

Saccular systems. With the evolution of multicellular organisms came a corresponding evolution of cellular specialization, resulting in a division of labour among cells; in this way, certain cells became specialized to perform the function of digestion for the entire organism. Cnidarians, especially hydra, provide a simple example. These radially

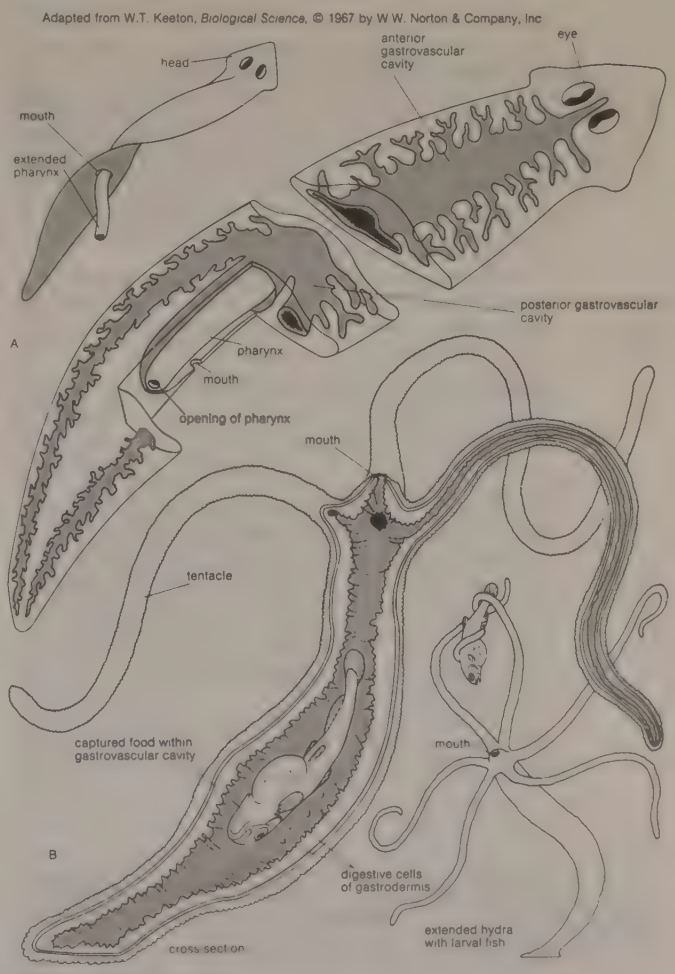

Figure 3: *Saccular systems.*
(A) Much-branched gastrovascular cavity and extruded pharynx of a planarian; (B) gastrovascular cavity of a hydra.

symmetrical animals have a saclike body composed of two principal layers of cells (Figure 3B). The cells of the outer layer function as a protective and sensory covering (epithelium); those of the inner layer, or gastrodermis, which lines the central cavity of the body, act as a nutritive epithelium. The central cavity, functioning as a digestive cavity, has only one opening to the outside; the opening acts both as a mouth for ingestion and as an anus for egestion. Such a digestive cavity is called a gastrovascular cavity, because in many animals it has vessel-like branches that convey the contents to all parts of the body.

The gastrovascular cavity

Once prey, captured by a hydra's tentacles, has been passed through the mouth into the gastrovascular cavity, digestive enzymes are secreted into the cavity by the gastrodermal cells, and extracellular digestion begins. In cnidarians, this extracellular digestion is limited largely to partial hydrolysis of proteins. As soon as the food has been partially disintegrated, the gastrodermal cells engulf the fragments by phagocytosis, and digestion is completed intracellularly within food vacuoles.

Many flatworms (phylum Platyhelminthes) also have gastrovascular cavities, even though their bodies are much more complex than those of cnidarians. In planarians, for example, the mouth opens into a tubular chamber called the pharynx, which in turn leads into a branched gastrovascular cavity that ramifies throughout the body (Figure 3A). As in cnidarians, some extracellular digestion occurs in the planarian gastrovascular cavity, with the small food particles then being engulfed by gastrodermal cells and digested intracellularly. The additional process of extracellular digestion frees cnidarians and flatworms from exclusive reliance on intracellular digestion.

Tubular systems. Most animals above the level of cnidarians and flatworms have a complete digestive tract; *i.e.*, a tube with two openings—a mouth and an anus. There are obvious advantages of such a system over a gastrovascular cavity, among them the fact that food moves in one direction through the tubular system, which can be divided into a series of distinct sections, each specialized for a different function. A section may be specialized for mechanical breakdown of bulk food, for temporary storage, for enzymatic digestion, for absorption of the products of digestion, for reabsorption of water, and for storage of wastes. The overall result is greater efficiency, as well as the potential for special evolutionary modifications for different modes of existence.

The earthworm tubular system

The digestive system of an earthworm is an example of a tubular system (Figure 4). Food, in the form of decaying organic matter mixed with soil, is drawn into the mouth by the sucking action of a muscular pharynx. From the pharynx and then through a connecting passage, called the esophagus, the food enters a relatively thin-walled storage chamber, or crop. Next, the food enters the gizzard, a compartment with thick muscular walls, and is ground up by a churning action, the grinding often being facilitated by bits of stone taken in with the food. The pulverized food, suspended in water, then passes into the long intestine, in which digestion and absorption take place. Most of the digestion is extracellular; cells of the intestinal lining secrete hydrolytic enzymes into the cavity of the intestine, and the end products of digestion, the simple compounds from which large molecules are formed, are absorbed. Finally, toward the rear of the intestine, some of the water is reabsorbed, and the indigestible residue is ultimately eliminated through the anus.

Not all large animals eat and grind up large pieces of food. Many are filter feeders; *i.e.*, they strain small particles of organic matter from water. Clams and many other mollusks filter water through tiny pores in their gills and trap microscopic food particles in streams of mucus that flow along the gills and enter the mouth; the mucus is kept moving by beating cilia. In such mollusks, digestion is largely intracellular, as might be expected in animals that eat microscopic food. Current theory holds that the earliest vertebrates were filter feeders. Some of the largest whales are examples of modern-day filter-feeding vertebrates; they strain small planktonic organisms from vast quantities of water.

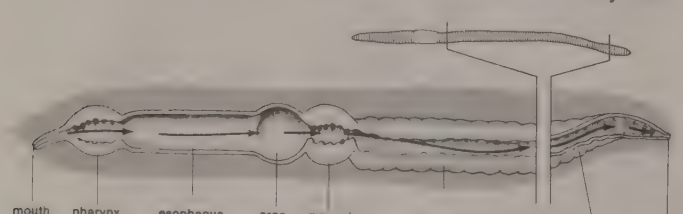

Figure 4: Digestive system of an earthworm.

A storage organ, such as the crop of the earthworm, enables an animal to take in large amounts of food quickly and to draw upon this stored matter over an extended period. Such a discontinuous feeding habit makes it possible for an animal to devote time to activities other than feeding. The majority of higher animals have evolved adaptations for discontinuous feeding, thereby gaining time for a behaviorally more varied existence.

Discontinuous feeding is frequently also of adaptive advantage in the feeding process itself. An animal's proper food, for example, may occur only in widely scattered locations; if it had to eat constantly to maintain itself, the animal would be unable to spend time searching for a new food supply or capturing more prey when the original supply had been depleted. The animal would thus have to live in an area in which there was an essentially unlimited and continuous source of food.

Animal food-storage organs are quite variable. In some animals they take the form of blind sacs (diverticula) branching off the digestive tract. Female mosquitoes, for example, have a large diverticulum that opens off the anterior portion of the digestive tract and runs posteriorly, occupying much of the abdominal cavity. The female mosquito locates a suitable animal, pierces its skin, and sucks blood until the diverticulum is filled. One large meal may suffice for the entire process of locating a site and laying her eggs—a matter of four or five days.

Food storage in mosquitoes

Embryology and evolution of the vertebrate digestive system

EMBRYONIC DEVELOPMENT

In amphioxus, an invertebrate member of the Chordata (the phylum to which all vertebrates belong), early divisions of the fertilized egg cell give rise to an embryo that is hollow and nearly spherical. Then an invagination (infolding) of cells at the vegetal (yolk) pole of the embryo converts the initially single-layered embryo into a two-layered one, a process called gastrulation. The new inner layer of cells, called endoderm (sometimes entoderm), surrounds a cavity, the archenteron, which has an opening to the exterior at the point at which invagination occurred; this opening is called the blastopore. The archenteron eventually becomes the cavity of the digestive tract, and the blastopore becomes the anus; the mouth arises as a new opening. In some invertebrates the reverse is true: the blastopore becomes the mouth, and the anus is the new opening.

The early stages of embryonic development in most vertebrates are not as simple as in amphioxus, largely because the egg cells contain much yolk or, in mammals, undergo specialized changes preparatory to implantation in the uterus. Thus, gastrulation is seldom a simple involution at the vegetal pole, and the blastopore, if indeed a "pore" appears at all, usually becomes overgrown with cells. Nevertheless, in all vertebrate embryos, an endodermal-lined cavity arises by some process that may be regarded as analogous to gastrulation in amphioxus, and this cavity develops into the digestive tract. Ordinarily, endoderm lines the yolk sac; forms a tube, called the foregut, that pushes forward into the head; and forms a second tube, the hindgut, that pushes into the posterior part of the embryonic body. Eventually, the surface tissue (ectoderm) of the embryo forms a small anterior invagination, the stomodeum, that meets the end of the foregut, and a similar posterior invagination, the proctodeum, that meets the end of the hindgut. Rupture of the tissues separating the stomodeum from the foregut and the proctodeum from the hindgut forms a tract with two openings to the exterior.

Embryonic derivations

It is apparent from the above description that short sections at both the anterior and the posterior ends of the digestive tract are of ectodermal origin. These correspond roughly to the oral cavity and to the anal canal, respectively. All the rest of the digestive tract, from the pharynx through the large intestine, is of endodermal origin. However, only the lining of the digestive tract is endodermal; the walls contain layers of muscle and connective tissue, which are of middle layer (mesodermal) origin. The endodermal lining gives rise by outpocketing to numerous organs, including the thyroid gland, gills or lungs, thymus, liver, pancreas, and urinary bladder.

EVOLUTIONARY DEVELOPMENT

In amphioxus, the digestive tract consists of only three components: the oral cavity, the pharynx, and a tubular postpharyngeal gut without subdivisions. The same condition holds in the most primitive living vertebrates, the cyclostomes (lampreys and hagfishes). In higher vertebrates, however, the postpharyngeal gut is almost always subdivided into a series of regions both anatomically and functionally distinct. The most common is the esophagus–stomach–small intestine–large intestine–rectum (or cloaca) sequence.

The oral cavity and pharynx vary considerably among the vertebrate classes. The variation correlates with the evolutionary changes in the respiratory system that accompanied the rise of terrestrial forms from aquatic ancestors. In most modern-day bony fishes, the nares (corresponding to a mammal's nostrils) function only as entrances to the olfactory organs, there being no connection between them and the mouth, as occurs in mammals. The structure called the palate, which in mammals separates the nasal and oral cavities, does not exist in fishes. Respiratory water is taken directly into the mouth and then forced back into the pharynx, where it flows across gills located in a series of slits leading from the pharynx to the exterior. Thus, the pharynx, with its gills, is an extremely important chamber in these animals.

The terrestrial vertebrates, which must extract oxygen from air instead of from water, evolved a second major function for the nares that they inherited from their piscine ancestors. While retaining a smell function, these openings became the principal entrance of air for breathing. In amphibians—the earliest land vertebrates—air enters the external nares (nasal openings) and then passes through the internal nares, which are evolutionarily newer openings, into the front of the oral cavity, whence it moves into the pharynx and then into the trachea. There being no palate, no separate nasal cavity exists in these animals; both the oral cavity and the pharynx are common passages for the digestive and respiratory systems.

In most reptiles and birds, a pair of longitudinal folds in the roof of the oral cavity forms a passage that leads air from the internal nares to the pharynx. Complete separation of nasal and oral cavities by a palate, however, is found only in crocodilians and in mammals. In mammals, the bony, hard palate is supplemented posteriorly by a thick, membranous, soft palate.

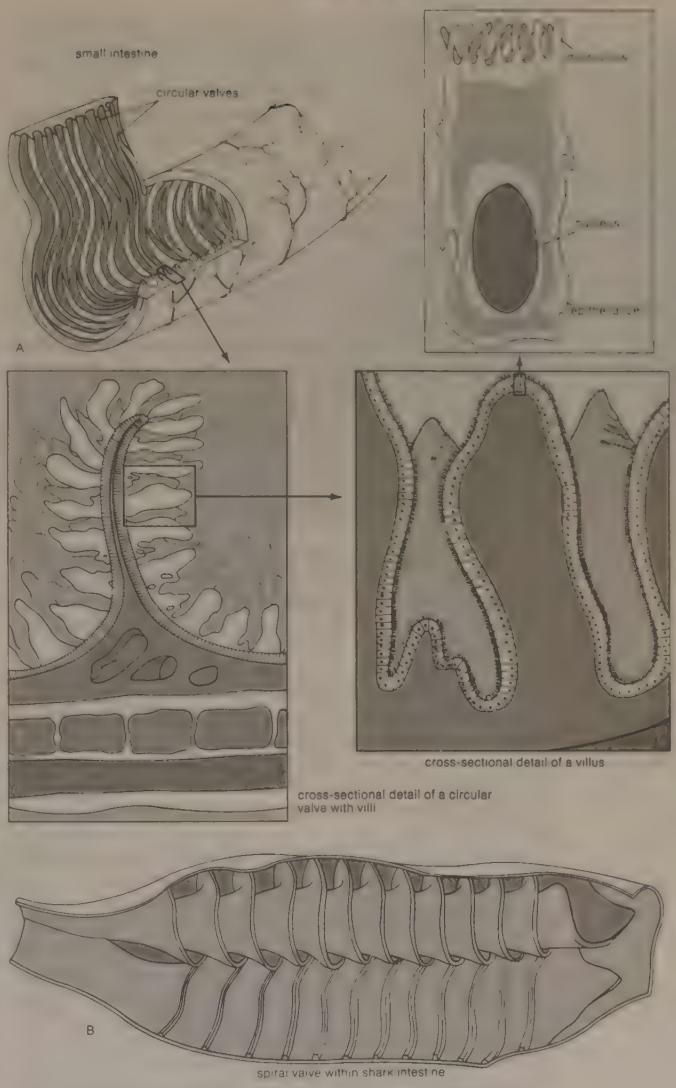

Figure 6: Structural modifications for increasing the surface areas of the small intestine.

Changes in the esophagus

In the evolution of terrestrial vertebrates the pharynx has lost the gas-exchanging gills and has become a short passage linking the mouth to the esophagus and the trachea. The esophagus has elongated to join up with the stomach, which now lies within the abdomen.

Most vertebrates above the level of the cyclostomes have a stomach, though of various shapes and sizes (the exceptions are the chimaeras, lungfishes, and a few bony fishes). The length of the intestine varies greatly among vertebrates, and a number of devices have evolved that increase the area over which absorption of digestive products can occur. Increasing length alone permits longer contact between the product of digestion and the mucosa. Other features of advantage include the lining of the intestine, which is thrown into numerous folds and ridges; the small, fingerlike outgrowths, called villi, that cover the entire surface of the mucosa; and the individual epithelial cells that cover the folds and villi and have a border of countless, closely packed, cylindrical projections called microvilli (Figure 6A).

Other vertebrates show other adaptations for increasing the absorptive surface area of the small intestine. For instance, it is not unusual for special blind sacs, called ceca,

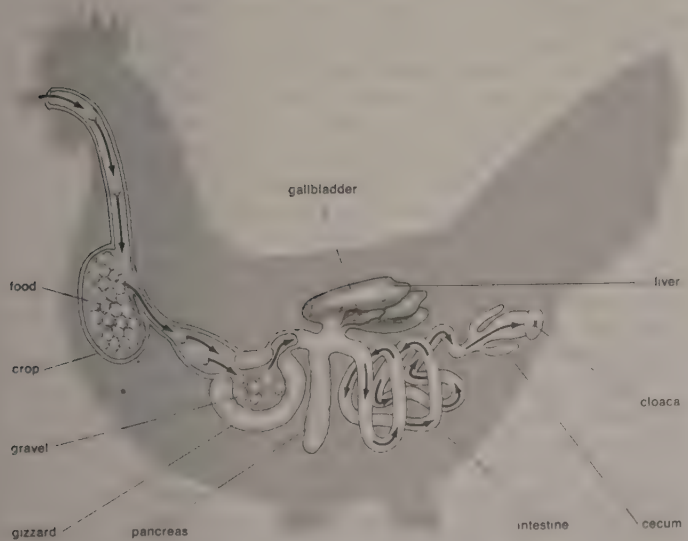

Figure 5: Digestive system of a chicken.

to branch from the anterior end of the small intestine in certain fishes and from the posterior end in many birds (Figure 5). Another adaptation is the spiral valve of many primitive fishes, including sharks (Figure 6B).

The final chamber of the digestive tract is a common cloaca in elasmobranch fishes and in lungfishes, but in most ray-finned fishes there is a rectum instead; *i.e.*, the urinary and reproductive tubes, which do not join the digestive tube, have their own separate opening to the exterior. In this regard, then, the modern-day ray-finned fishes are more specialized than amphibians, reptiles, and birds, which retain a cloaca, presumably inherited from a primitive fish ancestor. A cloaca is also retained in the egg-laying mammals (monotremes), and, in a much reduced form, in the pouched mammals (marsupials). Even in placental mammals, a short-lived cloaca appears in the embryo, but the urogenital ducts eventually develop their own openings, and, as a consequence of this, mammalian adults have a rectum rather than a cloaca.

(W.T.Ke./W.S.)

The vertebrate digestive system

The account below is based on the human digestive system. The first section deals with anatomy, the second with physiology. Both proceed through the anatomical divisions from the mouth to the anus. Other vertebrates are mentioned when they illustrate some important departure through specialization.

The human digestive system

The human digestive system consists of (1) the digestive tract, or the series of structures and organs through which food passes during its processing into forms absorbable into the bloodstream and also the structures through which solid wastes pass in the process of elimination, and (2) other organs that contribute juices necessary for the digestive process.

The digestive tract (Figure 7) begins at the lips and ends at the anus. It consists of the mouth, or oral cavity, with its teeth, for grinding the food, and its tongue, which serves to knead the food, mix it with saliva, and start it on its way to the stomach; the throat, or pharynx; the esophagus, or gullet; the stomach; the small intestine, consisting of the duodenum, the jejunum, and the ileum; and the large intestine, consisting of the cecum, a closed-end sac connecting with the ileum, the ascending colon, the transverse colon, the descending colon, and the sigmoid colon, which terminates in the rectum. Glands contributing digestive juices include the salivary glands, the gastric glands in the stomach lining, the pancreas, and the liver and its adjuncts—the gallbladder and bile ducts.

ANATOMY

Mouth and oral structures. *The lips.* The outer surface of the lips is covered with skin, the inner with mucous membrane. The mucosa is rich in mucus-secreting glands, which together with salivary mucus ensure adequate lubrication for the purposes of speech and mastication.

The cheeks. The cheeks, the sides of the mouth, are continuous with the lips and have a similar structure. A distinct fat pad is found in the subcutaneous tissue (the tissue beneath the skin) of the cheek; this pad is especially large in infants and is known as the sucking pad. On the inner surface of each cheek, opposite the second upper molar tooth (the second grinder tooth from the end), is the slight elevation that marks the opening of the parotid duct, leading from the parotid salivary gland, which is located in front of the ear. Just behind this gland are four to five mucus-secreting glands, the ducts of which open opposite the last molar tooth.

The roof of the mouth. The roof of the mouth is concave and is formed by the hard and soft palate. The hard palate is formed by the horizontal portions of the two palatine bones and the palatine portions of the maxillae, or upper jaws. The hard palate is covered by a thick, somewhat pale mucous membrane that is continuous with that of the gums and is bound to the upper jaw and palate bones by firm fibrous tissue. The soft palate is continuous with the hard palate in front and posteriorly has a free margin. The uvula, which varies greatly in size and shape, is a projection of the soft palate and hangs free from its rear margin. The soft palate is composed of a strong, thin, fibrous sheet, the palatine aponeurosis, and the glossopalatine and pharyngopalatine muscles.

The hard and soft palates

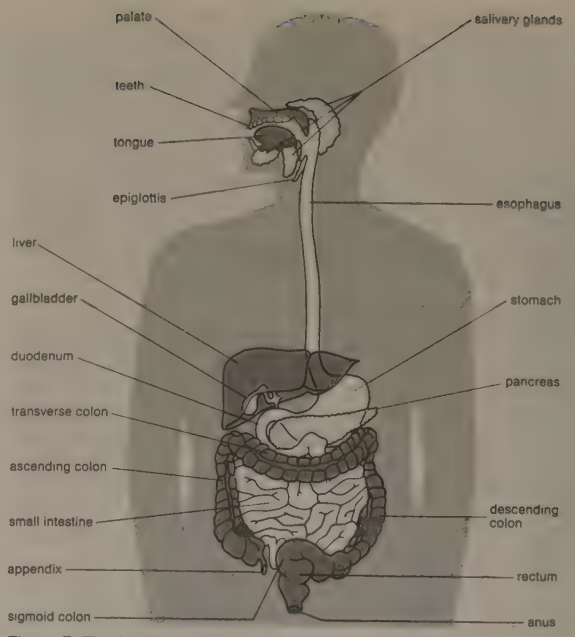

Figure 7: The human digestive system as seen from the front.

The floor of the mouth. The floor of the mouth can be seen only when the tongue is raised. In the midline is a prominent fold (frenulum linguae) like that which binds each lip to the gums, and on each side of this is a slight elevation called a sublingual papilla, onto the summit of which the ducts of the submaxillary salivary glands open. Running outward and backward from this is a ridge (the plica sublingualis) that marks the upper edge of the sublingual (under the tongue) salivary gland and onto which most of the ducts of that gland open.

The gums. The gums consist of mucous membranes connected by thick fibrous tissue to the membrane surrounding the bones of the jaw. Around the base of the crown (exposed portion) of each tooth the gum membrane rises to form a little collar. The gum tissues are rich in blood vessels, receiving branches from the alveolar arteries; these vessels, called alveolar from their relationship to the alveoli dentales, or tooth sockets, also supply the teeth and the spongy bone of the upper and lower jaws, in which the teeth are lodged. The veins and lymphatics of the gums correspond essentially to the arteries.

Specialized functions of teeth

The teeth. The teeth are hard white structures found in the mouth of humans and many other animals and usually are used for mastication. The teeth of different vertebrate species are sometimes specialized. The teeth of snakes, for example, are very thin and sharp and usually curve backward; they function in capturing prey but not in chewing, for snakes swallow their food whole. The teeth of carnivorous mammals, such as cats and dogs, are more pointed than those of primates, including humans; the canines are long, and the premolars lack flat grinding surfaces, being more adapted to cutting and shearing (often the more posterior molars are lost). On the other hand, herbivores such as cows and horses have very large, flat premolars and molars with complex ridges and cusps; the canines are often totally absent. Sharp pointed teeth, poorly adapted for chewing, generally characterize meat eaters such as snakes, dogs, and cats; and broad, flat teeth, well adapted for chewing, characterize vegetarians. The differences in the shapes of teeth are functional adaptations. Few animals can digest cellulose, yet the plant cells used as food by herbivores are enclosed in cellulose cell walls that must be broken down before the cell contents can be exposed to the action of digestive enzymes. By contrast, the animal cells in meat are not encased in nondigestible matter and can be acted upon directly by digestive enzymes. Conse-

quently, chewing is not so essential for carnivores as for herbivores. Dogs gulp their food; cows and horses spend much time chewing. Humans, who are omnivores (eaters of plants and animal tissue), have teeth that belong, functionally and structurally, somewhere between the extremes of specialization attained by the teeth of carnivores and herbivores. The members of one class of vertebrates, the birds, have no true teeth. Mechanical breakdown of food is accomplished in birds in a muscular gizzard (Figure 5) located behind the stomach; in the gizzard, hard food is ground with grit formed of ingested rocks and pebbles.

Each tooth consists of a crown and one or more roots. The crown is the functional part that is visible above the gum. The root is the unseen portion that supports and fastens the tooth in the jawbone. The shapes of the crowns and the roots vary in the different parts of the mouth and from one animal to another. Humans normally have two sets of teeth during their lifetime. The first set is acquired gradually between the ages of six months and two years. As the jaws grow and expand, these teeth are replaced one by one by the teeth of the secondary set. The first set is known as the milk, deciduous, or primary dentition. The teeth on one side of the jaw are essentially a mirror image of those located on the opposite side. The upper teeth differ from the lower and are complementary to them. There are five deciduous teeth and eight permanent teeth in each quarter of the mouth, making a total of 32 permanent teeth to succeed the 20 deciduous ones.

Functions of the tongue

The tongue. The tongue, a muscular organ located on the floor of the mouth, is an extremely mobile structure in humans and an important accessory organ in such motor functions as speech, chewing, and swallowing. In conjunction with the cheeks, it is able to guide and maintain food between the upper and lower teeth until mastication is completed. The tongue's motility aids in creating a negative pressure within the oral cavity, thus enabling mammals to suckle.

The mucous membrane that covers the tongue varies greatly. Especially important as a peripheral sense organ, it contains groups of specialized epithelial cells, known as taste buds, that carry stimuli from the oral cavity to the central nervous system. Furthermore, the tongue's glands produce some of the saliva necessary for swallowing.

The mammalian tongue consists of a mass of interwoven, striated (striped) muscles covered with mucous membrane and interspersed with glands and a variable amount of fat. By its extrinsic muscles, the tongue is attached to the lower jaw, the hyoid bone (a U-shaped bone between the lower jaw and the larynx), the skull, the soft palate, and the pharynx. It is bound to the floor of the mouth and to the epiglottis (a plate of cartilage that serves as a lid for the larynx) by folds of its mucous membrane.

Salivary glands. Besides the many minute glands that secrete saliva, there are three major pairs of salivary glands: the parotid, the submaxillary, and the sublingual glands.

Size, form, and location

The parotid glands, the largest of the pairs, are located at the side of the face, below and in front of each ear, in back touching the mastoid bone (which is behind the ear) and the sternomastoid muscle, the prominent muscle of each side of the neck, and in front shaped around the ascending portion of the bone of the lower jaw. The parotid glands are enclosed in sheaths that limit the extent of their swelling when inflamed, as in mumps. The submaxillary glands lie near the inner side of the lower jawbone, not far in front of the sternomastoid muscle. They are rounded in shape. The sublingual glands lie directly under the mucous membrane covering the floor of the mouth beneath the tongue.

The salivary glands are of the type called racemose, from the Latin *racemosus* ("full of clusters"), because of the cluster-like arrangement of their secreting cells in rounded sacs, called acini, attached to freely branching systems of ducts. The walls of the acini surround a small central cavity known as an alveolus. In the walls are pyramidal secreting cells and some flat, star-shaped cells called myoepithelial, or basket, cells. The latter cells are thought to contract, like the similar myoepithelial cells of the breast, which by their contraction expel milk from the milk ducts.

Types of secreting cells

The secreting cells may be of the serous or the mucous type. The latter type secretes mucin, the chief constituent of mucus; the former, a watery fluid containing an enzyme, amylase, which is also known as ptyalin. The secreting cells of the parotid glands are of the serous type; those of the submaxillary glands, of both serous and mucous types, with the serous cells outnumbering the mucous cells by four to one. The acini of the sublingual glands are composed primarily of mucous cells.

The parasympathetic nerve supply regulates secretion by the acinar cells and causes the blood vessels to dilate. Functions regulated by the sympathetic nerves include secretion by the acinar cells, constriction of blood vessels, and, presumably, contraction of the myoepithelial cells.

Pharynx. The pharynx, or throat, is the passageway leading from the mouth and nose to the esophagus and larynx. The pharynx permits the passage of swallowed solids and liquids into the esophagus, or gullet, and conducts air to and from the trachea, or windpipe, during respiration. The pharynx also connects on either side with the cavity of the middle ear by way of the Eustachian tube and provides for equalization of air pressure on the eardrum membrane, which separates the cavity of the middle ear from the external ear canal.

The pharynx has roughly the form of a funnel flattened from front to back. It is attached to the surrounding structures but is loose enough in organization to permit gliding of the pharyngeal wall against them, in the movements of swallowing.

Regional anatomy

Three main divisions of the pharynx are distinguished: the oral pharynx, the nasal pharynx, and the laryngeal pharynx. The latter two are airways, whereas the oral pharynx is shared by both the respiratory and alimentary (digestive) tracts. On either side of the opening between the mouth cavity and the oral pharynx is a tonsil called a palatine tonsil because of its proximity to the palate. Each palatine tonsil is between two vertical folds of mucous membrane (behind the glossopalatine arch and in front of the pharyngopalatine arch). The glossopalatine arches are located on the sides of the pharynx. The nasal pharynx, above, is separated from the oral pharynx by the soft palate. The laryngeal pharynx and the lower part of the oral pharynx are hidden by the bulging root of the tongue. An important feature of this obscured region is the epiglottis, or laryngeal flap, which acts as a deflector between the laryngeal pharynx and the lowermost oral pharynx and closes over the larynx during the act of swallowing.

The pharyngeal muscles are concerned in the mechanics of swallowing. The principal muscles of the pharynx are the three pharyngeal constrictors, which overlap each other slightly, from below upward, and form the primary musculature of the side and rear pharyngeal walls.

A series of lymphatic glands known as the tonsils encircle the oropharyngeal junction. Besides the palatine tonsils, there is one pair on the roof of the nasopharynx that, when grossly swollen, which is often during childhood, occlude the airway there, and then are known as adenoids. They are part of the body's immune-defense system.

Esophagus. The esophagus, which extends from the pharynx to the stomach, is about 25 centimetres (10 inches) in length; the width varies from one and one-half to two centimetres. The esophagus contains the four typical layers of the alimentary canal—mucosa (or mucous membrane), submucosa, muscularis, and tunica adventitia. The mucosa is made up of stratified squamous epithelium containing numerous mucous glands. The submucosa is a thick, loose fibrous layer connecting the mucosa to the muscularis. The mucosa and submucosa form long longitudinal folds so that a cross section of the esophagus opening would be star-shaped. The muscularis is composed of an inner layer in which the fibres are circular and an outer layer of longitudinal fibres. In fact both muscle groups are wound around and along the alimentary tract, but the inner one has a very tight spiral so that the windings are virtually circular, and the outer one has a very slowly unwinding spiral that is virtually longitudinal.

Layers of the esophagus

The outer layer of the esophagus, the tunica adventitia, is composed of loose fibrous tissue that connects the esophagus with neighbouring structures. Except during the act of swallowing, the esophagus is normally empty, and its

lumen, or channel, is essentially blocked by the longitudinal folds of the mucosal and the submucosal layers.

For the upper third of the esophagus the muscle is striated (capable of being contracted by volition). The middle third has a mixture of striated and smooth (involuntary) muscle, and the lower third only of smooth muscle. The esophagus has two sphincters. (Sphincters are circular muscles that act like drawstrings in closing channels.) The upper esophageal sphincter is located at the level of the cricoid cartilage (a single ringlike cartilage forming the lower part of the larynx wall). This sphincter is called the cricopharyngeus muscle. The lower esophageal sphincter encircles the three to four centimetres of the esophagus that pass through the diaphragmatic hiatus and is thus located partly above and partly below the diaphragm. Both sphincters normally remain closed except during the act of swallowing.

The lower esophageal sphincter

Stomach. The stomach serves as a reservoir and receives ingested food and liquids from the esophagus and retains them for admixing with the gastric juice in order that digestion can begin. It is located in the left upper part of the abdomen immediately below the diaphragm. In front of the stomach are the liver, part of the diaphragm, and the anterior abdominal wall. Behind it are the pancreas, the left kidney, the left adrenal, the spleen, and the colon. When the stomach is empty, it contracts, and the transverse colon ascends to occupy the vacated space.

The size, shape, and position of the stomach vary extremely and depend upon the extent of its contents as well as upon the tension in the muscles of its walls. The organ is more or less concave on its right side, convex on its left. The concave border is called the lesser curvature; the convex border, on the left and below, the greater curvature. The opening from the esophagus into the stomach is the cardia, while the outlet from the stomach into the duodenum is the pylorus.

The parts of the stomach

The various parts of the stomach may be summarized as follows. The uppermost part, located above the entrance of the esophagus, is the fundus; it frequently contains a gas bubble, especially after a meal. The cardia is that portion of the stomach surrounding the opening from the esophagus. The largest part of the stomach is the body; it serves primarily as a reservoir for ingested food and liquids. The antrum, the lowermost part of the stomach, is somewhat funnel-shaped, with its wide end joining the lower part of the body of the stomach and its narrow end connecting with the pyloric canal, which empties into the duodenum. The pyloric portion (antrum plus pyloric canal) of the stomach tends to curve to the right and slightly upward and backward and thus gives the stomach its J-shaped appearance. The pylorus, the narrowest portion of the stomach, is approximately two centimetres in diameter; it is surrounded by thick loops of smooth muscle.

When the stomach is empty, its mucosal lining is thrown into numerous longitudinal folds, known as rugae; these tend to disappear when the stomach is distended.

The surface of the gastric (stomach) mucosa is always covered by a layer of thick tenacious mucus that is secreted by the columnar cells of the surface. Beneath the surface epithelium various types of gastric glands are located that, in different parts of the stomach, vary in structure and in composition of their secretion. Thus, each area of the gastric mucosa is characterized by its glandular structure. When the gastric mucus is removed from the surface epithelium, small pits, called foveolae gastricae, may be observed with a hand magnifying glass. There are approximately 90 to 100 gastric pits per square millimetre (58,000 to 65,000 per square inch) of surface epithelium. Into each gastric pit from three to seven individual gastric glands empty their secretions.

The gastric glands

The gastric mucosa contains five different types of cells. In addition to the tall columnar surface epithelial cells mentioned above, there are three common cell types found in the various gastric glands. (1) Mucoid cells—cells that secrete mucus—are common to all types of gastric glands. Mucoid cells are the main cell type found in the gastric glands in the cardiac and pyloric areas of the stomach. The necks of the glands in the body and fundic parts of the stomach are lined with mucoid cells. (2) Other cells, called zymogenic, or chief, cells, are located predominantly in the gastric glands in the body and fundic portions of the stomach. These cells secrete pepsinogen, from which the enzyme pepsin is formed. (3) Cells called parietal, or oxyntic, cells, in the glands of the body and fundic portions of the stomach, secrete hydrochloric acid, most of the water found in gastric juice, and a protein called intrinsic factor (see below *Organ function*). (4) Endocrine cells, called enterochromaffin-like cells because of their staining characteristics, are scattered throughout the body of the stomach. (5) Other endocrine cells throughout the antrum secrete the acid-stimulating hormone gastrin.

Beneath the gastric mucosa is a thin layer of smooth muscle fibres called the muscularis mucosa, and below this, in turn, is loose connective tissue, the submucosa, which attaches the gastric mucosa to the muscles in the walls of the stomach.

The stomach muscles

The muscles of the gastric wall are arranged in three layers, or coats. The innermost layer of smooth muscle of the gastric wall, called the oblique muscular layer, is strongest in the region of the gastric fundus and progressively weaker as it approaches the pylorus.

The middle, or circular muscular layer, the strongest of the three muscular layers, completely covers the stomach. The circular fibres of this coat are best developed in the lower portion of the stomach, particularly over the antrum and the pylorus.

The external coat, called the longitudinal muscle layer, is formed from the longitudinal muscle coat of the esophagus. The longitudinal muscle fibres are divided at the cardia into two broad strips. The one on the right, the stronger, spreads out to cover the lesser curvature and the adjacent posterior and anterior walls of the stomach. The longitudinal fibres on the left sweep from the esophagus over the dome of the fundus of the stomach to cover the greater curvature and continue on to the pylorus, where they join the longitudinal muscle fibres coming down over the lesser curvature.

At the pyloric end of the stomach the middle layer of muscle, the circular layer, becomes greatly thickened to form the pyloric sphincter. This muscular ring is slightly separated from the circular muscle of the duodenum by connective tissue. The outer muscle layer of the stomach, the longitudinal layer, continues on into the duodenum, forming the longitudinal muscle of the small bowel.

Many branches of the celiac trunk bring arterial blood to the stomach. The celiac trunk is a short, wide artery that branches from the abdominal portion of the aorta, the main vessel conveying arterial blood from the heart to the systemic circulation. Blood from the stomach is returned to the venous system into the portal vein, which carries the blood to the liver.

The nerve supply to the stomach is provided by both the parasympathetic and sympathetic divisions of the autonomic nervous system. The parasympathetic nerve fibres are carried in the vagus, or 10th cranial, nerves. As the vagus nerves pass through the opening in the diaphragm together with the esophagus, branches of the right vagus nerve spread over the posterior part of the stomach, while the left vagus supplies the anterior part. Sympathetic branches from a nerve network called the celiac, or solar, plexus accompany the arteries of the stomach into the muscular wall.

Nerve supply

Small intestine. The small intestine, which is 670–760 centimetres in length, is the longest part of the digestive tract of humans. It begins at the pylorus, the juncture with the stomach, and ends at the ileocecal valve, the juncture with the colon. The parts of the small intestine are the duodenum, jejunum, and ileum.

The three parts of the small intestine. The duodenum is 23–28 centimetres long and forms a horseshoe, or C-shaped, curve that encircles the head of the pancreas. Unlike the rest of the intestine, it is retroperitoneal (that is, it is behind the peritoneum, the membrane lining the abdominal wall). Its first part, known as the duodenal bulb, is the widest part of the small intestine. It is horizontal, passing backward and to the right from the pylorus, and lies somewhat behind the wide end of the gallbladder. The second part runs vertically downward in front of the

hilum of the right kidney (the point of entrance or exit for blood vessels, nerves, and the ureters): it is into this part of the duodenum, through the papilla of Vater, that the pancreatic juice and bile flow. The third part runs horizontally to the left in front of the aorta and the inferior vena cava (the principal channel for return to the heart of venous blood from the lower part of the body and the legs), while the fourth part ascends to the left side of the second lumbar vertebra (at the level of the small of the back), then bends sharply downward and forward to join the second part of the small intestine, the jejunum. An acute angle, called the duodenojejunal flexure, is formed by the suspension of this part of the small intestine by the ligament of Treitz.

The jejunum and ileum

The jejunum forms the upper two-fifths of the rest of the small intestine; it, like the ileum, has numerous convolutions and is attached to the posterior abdominal wall by mesentery, a fold of serous—clear-fluid-secreting—membrane.

The ileum is the remaining three-fifths of the small intestine, though there is no absolute point at which the jejunum ends and the ileum begins. In broad terms, the jejunum occupies the upper and left part of the abdomen below the subcostal plane (*i.e.*, from a plane just above the floating ribs), while the ileum is located in the lower and right part. At its termination the ileum opens into the large intestine.

The small intestine mucosa. Although the small intestine is only three to four centimetres in diameter and approximately seven metres (23 feet) in length, it has been estimated that the total absorptive area of the human small intestine is approximately 4,500 square metres (5,400 square yards). This enormous absorptive surface is provided by the unique structure of the mucosa, which is arranged in concentric folds that have the appearance of transverse ridges. These folds are approximately five to six centimetres in length and about 3.2 millimetres thick. They are known as plicae circulares. These folds are present throughout the small bowel except in the first portion, or bulb, of the duodenum, which is usually flat and smooth, except for a few longitudinal folds. The plicae circulares are largest in the lower part of the duodenum and in the upper part of the jejunum. They become smaller and finally disappear in the lower part of the ileum. It has been estimated that the small intestine of humans contains approximately 800 plicae circulares and that they increase the surface area of the lining of the small bowel by five to eight times the outer surface of the small bowel.

Microstructure

Another feature of the small bowel mucosa that greatly multiplies its surface area is that of the tiny projections called mucosal villi. These mucosal villi usually vary from 0.5 to one millimetre in height. Their diameters vary from approximately one-eighth to one-third their height. The villi are covered by a single layer of tall columnar cells. Goblet cells, so called because of their rough resemblances to empty goblets after they have discharged their contents, are also found scattered among the surface cells. The goblet cells are a source of mucin, the chief constituent of mucus.

At the base of the mucosal villi are depressions called intestinal glands, or Lieberkühn's glands. The cells that line these glands continue up and over the surface of the villi. In the bottom of the glands, the epithelial cells are filled with alpha granules, or eosinophilic granules, so called because they take up the rose-coloured stain eosin. These cells have been termed the cells of Paneth. Though they may contain lysozyme, an enzyme toxic to bacteria, and immunoglobins, their precise function is uncertain.

There are three other cell types in these glands: undifferentiated cells that have the potential for undergoing changes for the purpose of replacing losses of any cell type, the goblet cells mentioned above, and endocrine cells, which are described below. The main functions of the undifferentiated cells in these glands are cell renewal and secretion. The surface epithelium coating the villi, on the other hand, is concerned with digestion and absorption. The epithelial cells covering the villi move progressively upward, maturing into one cell form or another. Those coating the villi have an average life of 72 hours in humans and most larger animals, before becoming exhausted and being cast off.

Anatomy of villi

In the duodenum the villi are closely packed and large and frequently are leaflike in shape. In the jejunum the individual villus measures between 350 and 600 microns in height (there are about 25,000 microns in an inch) and has a diameter of 110 to 135 microns. The appearance and shape of the villi vary in different levels of the small intestine. The inner structure of the individual villus consists of loose connective tissue containing a rich network of blood vessels, a central lacteal, or channel for lymph, smooth muscle fibres, and scattered cells of various types. The smooth muscle cells surround the central lacteal and provide for the pumping action required to initiate the flow of lymph out of the villus.

A small central arteriole (minute artery) branches at the tip of the villus to form a capillary network (the capillaries are the smallest of the blood vessels); the capillaries, in turn, empty into a collecting venule that runs to the bottom of the villus.

The vascular channels in the villi have a thin endothelial cell lining with tiny diaphragm-covered pores that have greater permeability to large molecules than the nonporous parts. Villus structure varies in different ethnic groups, but this may only reflect differences in diet and parasitism, especially with the worms that are endemic in Eastern and tropical countries.

The microvilli

The most remarkable feature of the small bowel mucosa is the rough surface of the epithelial cells, the cells covering the villi. This surface, called a brush border, consists of individual microvilli. The microvilli are approximately one-tenth micron in diameter and one micron in height; each epithelial cell may have as many as 1,000 microvilli. The microvilli play an important role in absorption of intestinal contents by enlarging the absorbing surface approximately 25 times and containing a number of enzymes.

Beneath the mucosa of the small intestine, as beneath that of the stomach, are the muscularis mucosae and the submucosa. The submucosa consists of loose connective tissue and contains many blood vessels and lymphatics. In the submucosa of the duodenum are located Brunner's glands, composed of acini (round sacs) and tubules that are twisting and have multiple branching. Brunner's glands empty into the base of Lieberkühn's glands in the duodenum. Their exact function is not known, but they do secrete a scanty clear fluid that contains mucus, bicarbonate, and a relatively weak proteolytic (protein-splitting) enzyme. In the submucosa of the jejunum, solitary nodules (lumps) of lymphatic tissue are located. There is more lymphatic tissue in the ileum, in aggregates of nodules known as Peyer's patches.

The arrangement of the muscular coats of the small intestine is uniform throughout the length of the intestine. There is an inner, circular layer that is thicker than the outer, longitudinal layer. The outermost covering of the small intestine is the peritoneum, a single layer of flattened epithelial cells.

The blood supply of the small intestine is from the superior mesenteric artery (a branch of the abdominal aorta) and from the superior pancreaticoduodenal artery (a branch of the hepatic artery). These vessels run between layers of the mesentery and give off large branches that form a row or series of connecting arches from which branches enter the wall of the small bowel. The blood from the intestine is returned by means of the superior mesenteric vein, which, with the splenic vein, forms the portal vein, which drains into the liver.

The small intestine has both sympathetic and parasympathetic innervation. The vagus nerves provide the parasympathetic innervation. The sympathetic is provided by branches from the superior mesenteric plexus, a nerve network close under the solar plexus, which follow the blood vessels into the small intestine and finally terminate in the two plexuses, or networks—Auerbach's, located between the circular and longitudinal muscle coats, and Meissner's, which is located in the submucosa. Numerous fibrils, both adrenergic (sympathetic) and cholinergic (parasympathetic) connect the two plexuses.

Large intestine. The large intestine serves as a reservoir

for the liquids emptied into it, through the ileocecal valve, from the small intestine. It has a much larger diameter than the small intestine. The large intestine, or colon, may be divided into the cecum, ascending colon, transverse colon, descending colon, and sigmoid colon. The primary function of the colon is to absorb water and electrolytes (substances, such as salts, that in solution take on an electrical charge) from the ileal contents and to store fecal material until it can be evacuated by defecation.

Anatomy of the colon

The cecum, the first part of the large intestine, is a sac with a closed end. It occupies the right iliac fossa, the hollow of the inner side of the ilium (the upper part of the hipbone). Guarding the opening of the ileum into the cecum is the ileocecal valve. Most textbooks of anatomy describe the ileocecal valve as consisting of two folds or flaps of mucous membrane on the cecal side and above and below the ileal opening. The ileocecal junction does have this appearance commonly after death. During life, however, the ileocecal junction appears much different in that the terminal portion of the ileum doubles into the cecum; from the cecal side the ileocecal valve greatly resembles the cervix, the projection of the uterus into the vagina. The circular muscle fibres of the ileum and those of the cecum combine to form the circular sphincter muscle of the ileocecal valve.

Regional anatomy

The ascending colon extends up from the cecum at the level of the ileocecal valve to the bend in the colon called the hepatic flexure, which is located beneath and behind the right lobe of the liver; behind, it is in contact with the rear abdominal wall and the right kidney. The ascending colon is covered by peritoneum except on its posterior surface.

The transverse colon is variable in position, depending largely on the distention of the stomach, but usually is located in the subcostal plane; that is, at the level of the 10th rib. On the left side of the abdomen it ascends to the bend called the splenic flexure, which may make an indentation in the spleen. The transverse colon is bound to the diaphragm opposite the 11th rib by a fold of peritoneum.

The descending colon passes down and in front of the left kidney and the left side of the posterior abdominal wall to the iliac crest, the upper border of the hipbone. The descending colon is more likely than the ascending colon to be surrounded by peritoneum.

The sigmoid colon is commonly divided into iliac and pelvic parts. The iliac colon stretches from the crest of the ilium, or upper border of the hipbone, to the inner border of the psoas muscle, which lies in the left iliac fossa. Like the descending colon, the iliac colon is usually covered by peritoneum. The pelvic colon lies in the true pelvis (lower part of the pelvis) and forms one or two loops, reaching across to the right side of the pelvis and then bending back and, at the midline, turning sharply downward to the point where it becomes the rectum.

The layers that make up the wall of the colon are similar in some respects to those of the small bowel; there are distinct differences, however. The external aspect of the colon differs markedly from that of the small bowel because of features known as the haustra, taeniae, and appendices epiploicae.

The haustra, bulges or sacculations, are formed by constricting circular furrows of varying depths. The three taeniae are long, narrow bands of longitudinal muscle fibres, about one centimetre in width, that are approximately equally spaced around the circumference of the colon. Between the thick bands of the taeniae there is a thin coating of longitudinal muscle fibres.

The appendices epiploicae are collections of fatty tissue beneath the covering membrane. On the ascending and descending colon they are usually found in two rows, whereas on the transverse colon they form one row.

Microstructure

The mucous membrane of the colon has a characteristic structure. It lacks the villi and the folds known as plicae circulares characteristic of the small intestine. It contains many solitary lymphatic nodules but no Peyer's patches. The surface epithelium is columnar, and there are many goblet cells. Characteristic of the colonic mucosa are deep tubular pits, increasing in depth toward the rectum.

The arterial blood supply to the large intestine is supplied by branches of the superior and inferior mesenteric arteries (both of which are branches of the abdominal aorta) and the hypogastric branch of the internal iliac (which supplies blood to the pelvic walls and viscera, the genital organs, the buttocks, and the inside of the thighs). The vessels form a continuous row of arches from which vessels arise to enter the large intestine. Venous blood is drained from the colon from branches that form venous arches similar to those of the arteries. These eventually drain into the superior and inferior mesenteric veins, which ultimately join with the splenic vein to form the portal vein.

The innervation of the large intestine is similar to that of the small intestine.

Rectum and anus. The rectum, which is a continuation of the sigmoid colon, begins in front of the midsacrum (the sacrum is the triangular bone near the base of the spine and between the two hipbones). It ends in a dilated portion called the rectal ampulla, which in front is in contact with the rear surface of the prostate in the male and with the posterior vaginal wall in the female. Posteriorly, the rectal ampulla is in front of the tip of the coccyx (the small bone at the very base of the spine).

Regional anatomy

At the end of the pelvic colon, the mesocolon, the fold of peritoneum that attaches the colon to the rear wall of the abdomen and pelvis, ceases, and the rectum is then covered by peritoneum only at its sides and in front; lower down, the rectum gradually loses the covering on its sides, until only the front is covered. At about the junction of the middle and lower thirds of the rectum, about 7.5 centimetres from the anus, the anterior peritoneal covering is also folded back onto the bladder and the prostate or the vagina.

Near the termination of the sigmoid colon and the beginning of the rectum, the colonic taeniae spread out to form a wide external longitudinal muscle coat. At the lower end of the rectum muscle fibres of the longitudinal and circular coats tend to intermix. The internal circular muscle coat terminates in the thick rounded internal anal sphincter muscle. The smooth muscle fibres of the external longitudinal muscle coat of the rectum terminate by interweaving with striated muscle fibres of the levator ani, a broad muscle that forms the floor of the pelvis. A second sphincter, the external anal sphincter, is composed of striated muscle and is divided into three parts known as the subcutaneous, superficial, and deep external sphincters. Thus, the internal sphincter is composed of smooth muscle and is innervated by the autonomic nervous system, while the external sphincters are of striated muscle and have somatic (voluntary) innervation provided by nerves called the pudendal nerves.

The mucosal lining of the rectum is similar to that of the sigmoid colon but becomes thicker and better supplied with blood vessels, particularly in the lower rectum. In the rectal ampulla are two to three large crescent-like folds known as rectal valves. These folds, or valves, are caused by an invagination, or infolding, of the circular muscle and submucosa. The columnar epithelium of the rectal mucosa changes to the stratified squamous (scalelike) type in the lower rectum a few centimetres above the pectinate line, which is the junction between squamous mucous membrane of the lower rectum and the skin lining the lower portion of the anal canal.

The rectal valves

Arterial blood is supplied by branches from the inferior mesenteric artery and the right and left internal iliac arteries. Venous drainage from the anal canal and rectum is provided by a rich network of veins called the internal and external hemorrhoidal veins. (N.C.H./W.S.)

Liver. The liver is not only the largest gland in the human body, but it is also the most complex in function. In humans, the liver lies under the lower right rib cage and occupies much of the upper right quadrant of the abdomen, with a portion extending into the upper left quadrant (Figure 8). The liver weighs from 1.2 to 1.6 kilograms (2.6 to 3.5 pounds) and is somewhat larger in men than in women. Its greatest horizontal measurement ranges from 20 to 22 centimetres; vertically, it extends 15 to 18 centimetres and in thickness it ranges from 10 to 13 centimetres. The liver is reddish brown, and its outline, when viewed from the front, resembles an asymmetrical

Lobes of the liver

rhomboid whose lateral vertical dimension is about three times as long as the medial side. In humans and other primates, the liver is divided into two unequal lobes: a large right lobe and a smaller left lobe. The left lobe is separated on its anterior (frontal) surface by the dense falciform (sickle-shaped) ligament that connects the liver to the undersurface of the diaphragm. On the inferior surface of the liver, the right and left lobes are separated by a groove containing the teres ligament, which runs to the umbilicus. Two small lobes, the caudate and the quadrate, occupy a portion of the inferior surface of the right lobe. The entire liver, except for a small portion that abuts the right leaf of the diaphragm, is enveloped in a capsule of tissue that is continuous with the parietal peritoneum, which lines the abdominopelvic walls and diaphragm.

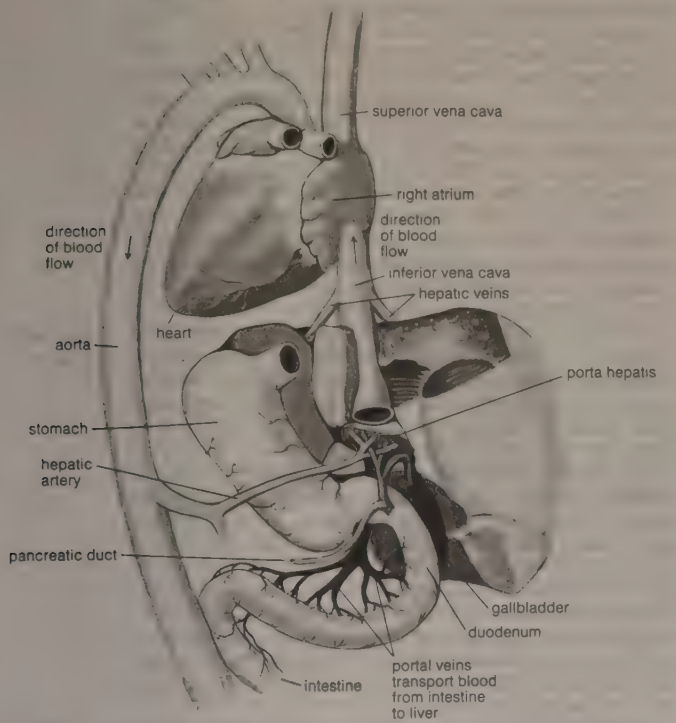

Figure 8: The liver and adjacent organs, as seen from behind.

The major blood vessels enter the liver on its inferior surface in a centrally placed groove called the porta hepatis, which anatomically separates the quadrate and caudate lobes. The liver has two sources of blood supply: fully oxygenated blood from the hepatic artery, which is a major branch of the celiac axis (the main artery that crosses the abdomen) after its emergence from the abdominal aorta; and partially oxygenated blood from the large portal vein, which in turn receives all venous blood from the spleen, pancreas, gallbladder, lower esophagus, and the remainder of the gastrointestinal tract, including the stomach, small intestine, colon, and upper portion of the rectum. The portal vein is formed by the juncture of the splenic vein with the superior mesenteric vein. At the porta hepatis, the portal vein divides into two large branches, each going to one of the major lobes of the liver. The hepatic duct, which also exits at the porta, is the final pathway for a network of smaller bile ductules interspersed throughout the liver that serve to carry newly formed bile from liver cells to the small intestine.

Microscopic anatomy

The microscopic anatomy of the liver reveals a uniform lobular structure throughout. Cords made up of numerous rectangular liver cells, or hepatocytes, are found to radiate from central veins, or terminal hepatic venules, toward a peripheral boundary defined by scant rims of connective tissue that establish the lobular border. A lobule measures about one millimetre in diameter. The liver cords are one-cell thick and are separated from one another on several surfaces by spaces called sinusoids, or hepatic capillaries. Sinusoids are lined by thin endothelial cells that have holes in their body (cytoplasm) through which fingerlike projections (microvilli) of the hepatocytes extend, allowing direct accessibility of the hepatocyte to the bloodstream in the sinusoids. The other major cell of the liver, the Kupffer cell, adheres to the wall of the sinusoid at intervals and projects into its lumen. It functions as a phagocyte (a cell that engulfs and destroys foreign material or other cells). Small spaces (Disse's spaces), probably for the transport of lymph, are present in places between the hepatocyte and the sinusoidal endothelium. On apposing surfaces, the hepatocytes are bound to one another by dense, tight junctions. These are perforated by small channels, called canaliculi, that are the terminal outposts of the biliary system, receiving bile from the hepatocyte. They eventually join with other canaliculi, forming progressively larger bile ducts that eventually emerge from the porta as the hepatic duct.

At the periphery of each hepatic lobule are found several areas containing three vessels. These portal areas contain terminal branches of the portal vein and the hepatic artery, conveying blood to the sinusoids, and a small bile duct that carries bile from the hepatic canaliculi. A single hepatic lobule may receive arterial and portal venous blood from and discharge bile into several portal areas.

Biliary tract. The extrahepatic biliary tract commences with the appearance of two large ducts, the right and left hepatic ducts, at the porta hepatis. Just below the porta, these two one- to two-centimetre ducts join to form the hepatic duct, which proceeds for another two to three centimetres and is joined by the cystic duct, leading from the gallbladder. The resulting common bile duct progresses downward through the head of the pancreas. There it is usually joined by the main pancreatic duct of Wirsung at a slightly dilated area called the ampulla of Vater, which lies in the wall of the inner curve of the descending duodenum, and terminates in the lumen of the duodenum at a two- to three-centimetre elevation called the papilla of Vater. The common bile duct averages about 10 centimetres in length, and flow of bile from its lower end into the intestine is controlled by the muscular action of the sphincter of Oddi located in the papilla of Vater. Total daily flow of bile into the intestine ranges from 600 to 800 millilitres. The cystic duct varies from two to three centimetres in length and terminates in the gallbladder, a saccular structure with a capacity of about 50 millilitres. Throughout its length, the cystic duct is lined by a spiral mucosal elevation, called the valvula spiralis (valve of Heister). Normally, the gallbladder lies partially embedded on the undersurface of the right lobe of the liver.

Common bile duct

Pancreas. The human pancreas weighs between 90 and 120 grams. It is a long, narrow gland that is situated transversely across the upper abdomen in the space behind the posterior peritoneum. Its somewhat bulbous head lies against the inner curve of the C-shaped loop formed by the curve of the second portion of the duodenum. The body and tail of the pancreas rise upward and leftward from the head, lying behind the stomach and the spleen. The midportion of the body lies against the vertebral column, the abdominal aorta, and the inferior vena cava.

Dual glandular role of the pancreas

The pancreas is both an exocrine (ductal) and endocrine (ductless) gland. The exocrine acinar tissue produces important digestive enzyme precursors that are transmitted into the small intestine, while the islets of endocrine tissue (islets of Langerhans) produce at least two hormones (insulin and glucagon) that are important in the regulation of carbohydrate metabolism and others (vasoactive intestinal polypeptide and somatostatin) that are pivotal elements in the control of intestinal secretion and motility. Acinar and ductal tissue arise from multiple sites along the primordial epithelial buds, and islet cell tissue arises from other sites. These two separate tissues mix with one another during early fetal life, but each retains its own distinctive character, acinar tissue being linked to the ductal system, and islet tissue having no ductal connections. Distinctly separate islet and acinar tissue are detectable microscopically by the 19th week of intrauterine life.

Histologically, individual acinar cells have the shape of a truncated pyramid, arranged in groups around a central ductal lumen. These central ducts empty into progressively larger intercalated and collecting ducts that eventually join

the duct of Wirsung. This main pancreatic duct enters the ampulla of Vater, where, in about 80 percent of instances, it is joined by the common bile duct. Occasionally the junction with the common bile duct is proximal to the ampulla, and in a few cases the duct of Wirsung and the common bile duct join the duodenum separately. There are at least three types of islet cells, designated alpha (or A), beta (or B), and delta (or D), which constitute about 2 percent of the total pancreatic mass. Islet cells are about 20 to 35 percent alpha, 60 to 75 percent beta, and 5 percent delta. Alpha cell granules contain only glucagon, whose release leads to the breakdown of glycogen in the liver and elevation of the level of blood glucose, while beta cell granules contain insulin, whose effects are the opposite of glucagon. (H.J.Dw.)

ORGAN FUNCTION

Mouth and oral structures. Little digestion of food takes place in the mouth; however, food is prepared in the mouth for transport through the upper alimentary canal, thus aiding the digestive processes that take place in the stomach and small intestine.

Mechanical activities

Mastication, or chewing, is the first mechanical process to which food is subjected. Movements of the lower jaw in chewing are brought about by the muscles of mastication (the masseter, the temporal, the medial and lateral pterygoids, and the buccinator). The sensitivity of the peridontal membrane that surrounds and supports the teeth, rather than the power of the muscles of mastication, limits the force of the bite.

Mastication is not essential for adequate digestion and nutrition. Chewing does aid digestion, however, by reducing food to small particles and mixing it with the saliva secreted by the salivary glands. The saliva lubricates and moistens dry food, while chewing distributes the saliva throughout the food mass. The movement of the tongue against the hard palate and the cheeks helps to form a rounded mass, or bolus, of food.

Salivary glands. The oral cavity has other functions in addition to those associated with mastication. It is there that food is tasted and mixed with saliva secreted by several sets of salivary glands. The saliva dissolves some of the food and acts as a lubricant, facilitating passage through the subsequent portions of the digestive tract. The saliva of some mammals, including humans, also contains a starch-digesting enzyme called amylase (ptyalin), which initiates the process of enzymatic hydrolysis; it splits starch (a polysaccharide containing many sugar molecules bound in a continuous chain) into molecules of the double sugar maltose. Many carnivores, such as dogs and cats, have no amylase in their saliva; hence their natural diet contains very little starch.

Control of salivary secretion

The salivary glands are controlled by the two divisions of the autonomic nervous system (sympathetic and parasympathetic), and it is generally held that this innervation is exclusively responsible for regulation of the glands' secretory activity. No hormone appears to be involved. Normally secretion of saliva is constant, regardless of the presence of food in the mouth. When something touches the gums, the tongue, or some region of the mouth lining, or when chewing occurs, the amount of saliva secreted increases. The stimulating substance need not be food—dry sand in the mouth or even moving the jaws and tongue when the mouth is empty are effective in increasing the salivary flow. This coupling of direct stimulation to the oral mucosa with increased salivation is known as the unconditioned salivary reflex. When an individual learns that a particular sight, sound, smell, or other stimulus is regularly associated with food, that stimulus alone may suffice to stimulate increased salivary flow. This response is known as the conditioned salivary reflex.

A variety of drugs are capable of increasing or decreasing salivary flow. Two types of drugs that increase the flow of saliva are sympathomimetic agents, or drugs that produce effects similar to those elicited by the sympathetic nervous system (*e.g.*, epinephrine [adrenaline], norepinephrine [noradrenaline], and amphetamine), and parasympathomimetic agents, or drugs that mimic the effects of the parasympathetic nervous system (*e.g.*, acetylcholine and pilocarpine). Among the drugs that decrease salivary flow are antagonists of epinephrine and norepinephrine (*e.g.*, ergotamine and dibenzylchlorethamine) and antagonists of acetylcholine (*e.g.*, atropine and scopolamine).

Chemistry

The composition of saliva varies, but its principal components are water, inorganic ions similar to those commonly found in the blood plasma, and a number of organic constituents. The amount of saliva secreted by a human in 24 hours usually amounts to one to 1.5 litres. Although saliva is slightly acidic, the bicarbonates and phosphates contained within it serve as buffers and maintain the pH, or hydrogen ion concentration, of saliva relatively constant under ordinary conditions.

The concentrations of bicarbonate, chloride, and sodium in saliva are directly related to the rate of flow. There is also a direct relation between the bicarbonate concentration and the partial pressure of carbon dioxide in the blood. The concentration of chloride varies from five millimoles per litre at low flow rates, to 70 millimoles per litre when it is high. The sodium concentrations in similar circumstances vary from five millimoles per litre to 100 millimoles per litre. The concentration of potassium is often higher than that in the blood plasma, up to 20 millimoles per litre, which accounts for the sharp and metallic taste of saliva when flow is brisk. Organic constituents of saliva consist of salivary proteins, free amino acids, specific blood group substances, and the enzymes lysozyme and amylase. Glucose is normally absent from saliva even in individuals with diabetes.

Functions of saliva

The main functions of saliva are to initiate the digestion of starch, to keep the mucous membranes of the mouth moist, and to facilitate speech. The constant flow of saliva keeps the oral cavity and teeth comparatively free from food residues, sloughed epithelial cells, and foreign particles. By removing material that may serve as culture media, saliva inhibits the growth of bacteria. Lysozyme serves a protective function, for it has the ability to lyse, or dissolve, certain bacteria. Taste is mediated by chemical mechanisms, and substances must be in solution for the taste buds to be stimulated. Saliva provides the solvent for food materials. The secretion of saliva also provides a mechanism whereby certain organic and inorganic substances can be excreted from the body, including mercury, lead, potassium iodide, bromide, morphine, ethyl alcohol, and certain antibiotics, such as penicillin, streptomycin, and chlortetracycline.

Although saliva is not essential to life, its absence results in a number of inconveniences, including dryness of the oral mucous membrane, poor oral hygiene because of bacterial overgrowth, a greatly diminished sense of taste, and difficulties with speech.

Pharynx. The first stage of deglutition, or swallowing, consists of passage of the bolus into the pharynx and is initiated voluntarily. The front part of the tongue is retracted and depressed, mastication ceases, respiration is inhibited reflexly, and the back portion of the tongue is elevated and retracted against the hard palate. This action, produced by the strong muscles of the tongue, forces the bolus from the mouth into the pharynx. Pressures as great as 100 centimetres of water have been recorded in the posterior part of the oral cavity during swallowing.

At the same time, the larynx moves upward and forward under the base of the tongue. The superior pharyngeal constrictor muscles contract, initiating a rapid pharyngeal peristaltic, or squeezing, contraction that moves down the pharynx, propelling the bolus in front of it. The walls and structures of the lower pharynx are elevated to engulf the oncoming bolus. The epiglottis, a lidlike covering that protects the entrance to the larynx, diverts the bolus to the pharynx. The cricopharyngeal muscle, or upper esophageal sphincter, which has kept the esophagus closed until this point, relaxes as the bolus approaches and allows it to enter the upper esophagus. The pharyngeal peristaltic contraction continues into the esophagus and becomes the primary esophageal peristaltic contraction.

The swallowing reflex is coordinated so well that food normally takes only one path, namely, that into the esophagus. Return of the bolus into the mouth is prevented by the position of the tongue against the hard palate. Entry

into the nasal pharynx is prevented by the elevation of the soft palate against the posterior pharyngeal wall. Entry into the larynx is prevented because the larynx is drawn under the base of the tongue and because the epiglottis diverts material away from the laryngeal opening.

Esophagus. Transport through the esophagus is accomplished by the primary esophageal peristaltic contractions that originated in the pharynx. The primary esophageal peristaltic contraction is produced by an advancing peristaltic wave that creates a pressure gradient and sweeps the bolus ahead of it. Transport of material through the esophagus requires approximately 10 seconds. When the bolus arrives at the junction with the stomach, the lower esophageal sphincter relaxes and the bolus enters the stomach. If the bolus is too large, or if the peristaltic contraction is too weak, the bolus may become arrested in the middle or lower esophagus. When this occurs, secondary peristaltic contractions originate around the bolus in response to the local distension of the esophageal wall and propel the bolus into the stomach.

Esophageal function

In some vertebrates the esophagus is not merely a tubular connection between the pharynx and the stomach, but rather may serve as a storage reservoir, or an ancillary digestive organ. In many birds, for example, an expanded region of the esophagus anterior to the stomach forms a thin-walled crop (Figure 5), which is the bird's principal organ for the temporary storage of food. Some birds also use the crop to carry food to their young. Ruminant mammals, such as the cow, are often said to have four "stomachs." Actually, the first three of these chambers (rumen, reticulum, and omasum) are thought to be derived from the esophagus. Vast numbers of bacteria and protozoans live in the rumen and reticulum. When food enters these chambers, the microbes begin to digest and ferment it, breaking down not only protein, starch, and fats, but cellulose as well. The larger, coarser material is periodically regurgitated as the cud, and after further chewing, the cud is reswallowed. Slowly the products of microbial action, and some of the microbes themselves, move into the cow's true stomach and intestine, and further digestion and absorption take place. Since the cow, like other mammals, has no cellulose-digesting enzymes of its own, it relies upon the digestive activity of these symbiotic microbes in its digestive tract. Much of the cellulose in the cow's herbivorous diet, which otherwise would have no nutritive value, is thereby made available to the cow.

Lower esophageal sphincter

In humans, the tone of the lower esophageal sphincter is maintained at all times, except in response to a descending contraction wave, at which point it relaxes momentarily to allow the eructation of gas (belching) or vomiting. The sphincter has an important role, therefore, in protecting the esophagus from the reflux of gastric contents with changes in body position or with alterations of intragastric pressure. In animals, gastroesophageal reflux is prevented in different ways. For example, in the three-toed sloth, which spends much of its time hanging upside down, there are three large septa, or folds, in the upper end of the stomach, which are aligned so that when the upper stomach is distended the septa come into juxtaposition and completely shut off the cavity of the stomach from the esophagus.

When a liquid bolus is swallowed, its transport through the esophagus depends somewhat on the position of the body and the effects of gravity. When swallowed in a horizontal or head-down position, liquids are handled in the same manner as solids, with the liquid bolus moving immediately ahead of the advancing peristaltic contraction. (The high pressures and strong contractions of the esophageal peristaltic wave make it possible for animals with very long necks, such as the giraffe, to transport liquids through the esophagus to a height of many feet.) When the body is in the upright position, liquids enter the esophagus and fall to the lower end and await the arrival of the peristaltic contraction and the opening of the lower esophageal sphincter (eight to 10 seconds), before being emptied into the stomach.

Stomach. The uppermost third of the stomach, or fundus, adapts to the varying volume of ingested food by relaxing its muscular wall, holding the food while it undergoes the first stages of digestion. The middle third, or body, of the stomach contains a mucosal lining that has glands which house the chief cells and the parietal cells. The chief cells produce the proteolytic (protein-digesting) enzymes, the pepsins. The parietal cells secrete hydrogen ions into a branching system of tiny canals (canaliculi) within the cell, where they combine with chloride to form hydrochloric acid. The parietal cells also secrete intrinsic factor, a protein that is concerned with the liberation of vitamin B_{12}. Endocrine cells in the mucosal glands of the lower third, or antrum, of the stomach, produce the hormone gastrin. When gastrin is secreted in response to a meal or other stimuli, it enters the bloodstream and is carried in the circulation to the mucosa of the body of the stomach. There it binds to receptor sites on the outer membrane of the parietal cells. The gastrin-receptor complex that is formed triggers the metabolic steps within the cell that lead to the production and secretion of hydrogen ions and the formation of hydrochloric acid.

The stomach serves as a temporary reservoir for ingested food and liquids. Its size, shape, and capacity vary from one person to another and also within the same person. The stomach is capable of dilating to accommodate more than one litre of food or liquids without increasing intraluminal pressure within the stomach. This receptive relaxation of the upper part of the stomach to accommodate a meal is partly due to a neural reflex that is triggered when hydrochloric acid comes into contact with the mucosa of the antrum, possibly through the release of the hormone known as vasoactive intestinal peptide (see below *Small intestine*).

The stomach mixes the food with the gastric juices and renders the ingested meal more soluble, preparing it for further digestion in the small intestine. Factors that influence the digestive activity of the stomach include its mobility, the rate of emptying of the gastric contents into the small intestine, and the secretion of hydrochloric acid and enzymes.

Mobility. Three types of motor activity of the human stomach have been observed. The first is a small contraction wave of the stomach wall that originates in the upper part of the stomach and slowly moves down over the organ toward the pyloric sphincter (the opening into the small intestine at the distal end of the stomach). This type of contraction produces a slight indentation of the stomach wall and is thought to serve the purpose of mixing the gastric contents. The second type of motor activity is also a contracting wave, but it is peristaltic in nature. The contraction originates in the upper part of the stomach as well and is slowly propagated over the organ toward the pyloric sphincter. This type of gastric contraction produces a deep indentation in the wall of the stomach. As the peristaltic wave approaches the antrum, the indentation completely obstructs the lumen, thus compartmentalizing it. The contracting wave then moves over the antrum, propelling the material ahead of it through the pyloric sphincter into the duodenum. This type of contraction serves as a pumping mechanism for emptying the contents of the gastric antrum through the pyloric sphincter. The third type of gastric motor activity is best described as a tonic, or sustained, contraction of all of the muscles of the organ. It decreases the size of the lumen of the stomach, as all parts of the gastric wall seem to contract simultaneously. It is this type of activity that accounts for the stomach's ability to accommodate itself to varying volumes of gastric content. The tonic contraction is independent of the other two types of contractions; however, mixing contractions and peristaltic contractions normally are superimposed upon the tonic contraction.

Types of motor activity

Both the mixing and the peristaltic contractions of the human stomach occur at a constant rate of three per minute when recorded from the gastric antrum. This rate is now recognized as the basic rhythm, although some drugs are capable of abolishing both types of contractions or of stimulating the strength of contractions.

In the higher vertebrates and in humans, a wave of peristalsis sweeps along the lower half of the stomach and along the entire intestine to the proximal colon at two-hour intervals after meals. These peristaltic waves can be

halted by eating and can be induced by an intravenous infusion of a hormone, motilin.

Gastric emptying. The distension of the body of the stomach by food activates a neural reflex that initiates the activity of the muscle of the antrum. Retrograde waves frequently sweep from the pyloric sphincter to the antrum and up to its junction with the body of the stomach, resulting in a to-and-fro movement of the gastric contents that has a mixing and crushing effect. As the food is broken down, small particles flow through the pyloric sphincter, which opens momentarily as a peristaltic wave descends through the antrum toward it. This permits "sampling" of the gastric contents by the duodenum (the uppermost division of the small intestine). Larger particles are swept back for further grinding. When receptors in the duodenal bulb (the area of attachment between the duodenum and the stomach) have a fluidity and a hydrogen ion concentration at a certain level the duodenal bulb and the second part of the duodenum relax, allowing emptying of the stomach to start. The vagus nerve of the central nervous system has an important role in the control of emptying, but studies on paraplegia caused by injury to the spinal cord indicate that the sympathetic division of the autonomic nervous system is also involved.

Emptying process

Liquids empty according to the pressure gradient between the stomach and duodenum. During a duodenal contraction, the pressure in the duodenal bulb rises higher than that in the antrum, but the pylorus then acts like most other alimentary sphincters and prevents reflux by shutting. In pyloroplasty, an operation in which the encircling muscle fibres of the sphincter are cut, there is little effect upon the rate of gastric emptying. Solids empty when the masses are sufficiently reduced in size and nearly soluble. Several of the peptide hormones of the alimentary tract have an effect on intragastric pressure and gastric movements, but their role in physiological circumstances is unclear.

Gastric secretion. The gastric mucosa that lines the stomach of humans secretes 1.2 to 1.5 litres of gastric juice per day. This juice is highly acidic because of its hydrochloric acid content, and it is rich in enzymes. Gastric juice renders food particles soluble, initiates digestion (particularly of proteins), and converts the gastric contents to a semiliquid mass, called chyme, thus preparing it for the small intestine and further digestion. The composition of the gastric juice varies according to the stimulus. It is a mixture of water, hydrochloric acid, electrolytes (sodium, potassium, calcium, phosphate, sulphate, and bicarbonate), and organic substances (mucus, pepsins, and protein).

Hydrochloric acid is produced by the parietal cells when one or more types of receptors on the outer membrane of the parietal cell are bound to one of three substances (histamine, gastrin, or acetylcholine) that have a particular molecular structure specific for a certain type of receptor. Histamine, probably released from mast cells that are present near the parietal cells, is a response to food entering the stomach. Gastrin, released from the endocrine cells in the antrum, is a response to lowered acidity of the gastric contents when food enters the stomach. Acetylcholine, released when stimuli descend the vagus nerve, is a response to the aesthetic and gustatory aspects of feeding and to the physical effects of chewing and swallowing. Histamine release may have a central role as the final common pathway by which the parietal cell is activated, the other stimulants working by first activating the mast cells.

As the gastric contents become less acidic, gastrin is released and travels in the blood to receptor sites on the exterior of the parietal cells of the stomach. In these cells, an energy-consuming reaction moderated by the presence of ATPase bound to the membrane gives off hydrogen ions (protons). Intracellular hydrogen ions are exchanged for extracellular potassium ions, which become vehicles for transporting intracellular chloride ions to the canaliculi, where they form hydrochloric acid (HCl) with free hydrogen ions already extruded from the cell. Inhibition of this proton pump by a drug, omeprazole, stops the secretion of acid and is a promising treatment for peptic ulcer. The acid that is collected in the canaliculi within the parietal cell drains into the lumen of the gland and then passes through to the stomach. The chief cells secrete the zymogen, or proenzyme (precursor), pepsinogen, which is converted to the active enzyme, pepsin, by hydrochloric acid. This conversion is achieved by inserting water into the precursor molecules. Some other enzymes, including lipase and carbonic anhydrase, can be found, but their origin is uncertain.

Production of acid

Gastric mucus is a glycoprotein that serves two purposes: the lubrication of food masses, facilitating movement within the stomach, and the formation of a protective layer over the lining epithelium of the stomach cavity. This protective layer is a defense mechanism the stomach has against being digested by its own protein-lyzing enzymes, and it is facilitated by the secretion of bicarbonate into the surface layer from the underlying mucosa. The physical character of mucus—its viscosity, resistance to penetration by hydrogen ions, and the thickness of the layer over the mucosa—varies, although the mechanisms of this are unknown. Nonsteroidal anti-inflammatory drugs, including aspirin and those used in the treatment of arthritis, degrade mucus and reduce its protective properties. When these agents damage the mucosa, however, bicarbonate is secreted in increasing amounts, so that the result will depend on the balance of these opposing forces.

The acidity, or hydrogen ion concentration, in the "unstirred" layer of mucus on the surface of the mucosa is a gradient that is measured at pH7 (neutral) at the area immediately adjacent to the epithelium and becomes more acidic (pH2) at the luminal level. Pepsin and acid secreted from the glands dissolve mucus glycoprotein in the gastric lumen, but this is replenished continually with viscous undegraded mucus from the mucosa.

Another element in the protection of the stomach walls from digestive juices is the membrane on the surface of the epithelial cells bordering the lumen of the stomach: this membrane is rich in lipoproteins, which are resistant to attack by acid. Most invertebrates do not have proteolytic enzymes active in an acid milieu, whereas most vertebrates have some enzymes activated by acid and others activated by alkali.

Derived from dietary lipids in response to various chemical and hormonal stimuli, the prostaglandins are hormonelike substances that are present in virtually all animal tissues and body fluids. The many different prostaglandins are designated by combinations of letters and numbers according to the chemical structure. Their synthesis in the body reflects the major fatty acids in the diet. In humans, arachidonic acid is the precursor of most prostaglandins. Prostaglandins are involved in the contraction and dilatation of blood vessels, the aggregation of platelets (clotting), and the contraction and relaxation of the smooth muscle of the gastrointestinal tract. Prostaglandins also inhibit the secretion of hydrochloric acid by the stomach in response to food, histamine, and gastrin. On a molecular level, prostaglandin PGE_2 is a thousand times as potent as H_2-receptor antagonists in inhibiting acid secretion. Prostaglandins are able to protect the mucosa of the alimentary tract from injury by various insults, including boiling water, alcohol, aspirin, bile acids, hypertonic saline, and stress. This protection is not related to their ability to influence acid secretion. Prostaglandins increase the secretion of mucus and bicarbonate from the mucosa, and they stimulate the migration of cells to the surface for repair and replacement of the mucosal lining.

Prostaglandins

Vitamin B_{12}-binding glycoproteins, present in gastric juice, are designated IF and IF_R according to the rate at which they move during electrophoresis. They are secreted from the pepsinogen-producing chief cells in some vertebrates and from the acid-producing parietal cells in others, including humans. IF_R binds vitamin B_{12} more strongly than does IF. (Vitamin B_{12} is essential to the maturation of red blood cells and to the health of certain cells in the central and peripheral nervous systems.) Because only a fraction of the total IF and IF_R that is produced is necessary, the number of parietal cells must be markedly diminished before a deficiency state appears. In a rare disorder, IF secretion is absent, although acid production is normal.

There are two varieties of protein-splitting proenzymes,

Pepsinogen

known as pepsinogen I and pepsinogen II. Both are produced in the mucous and chief cells in the glands of the body of the stomach, but the mucous glands that are distributed elsewhere in the stomach produce only pepsinogen II. The ability of the pepsins to break down protein (proteolysis) is restricted by the necessity for an acidic background with a pH between 1.8 and 3.5. Those stimuli that excite gastric acid secretion, in particular, vagal nerve stimulation, also promote the secretion of the pepsinogens. Pepsinogen I is useful as a genetic marker that signals the inheritance of gastric diseases. When acid secretion is supranormal, so, as a rule, is the secretion of pepsinogen I.

Phases of gastric secretion. The process of gastric secretion can be conveniently divided into three phases (cephalic, gastric, and intestinal). These phases depend upon the primary mechanisms that cause the gastric mucosa to secrete gastric juice.

The cephalic phase of gastric secretion occurs in response to stimuli received by the senses; that is, taste, smell, sight, and sound. This phase of gastric secretion is entirely reflex in origin and is mediated by the vagus (10th cranial) nerves. The gastric juice that is secreted in response to vagal stimulation, either directly by electrical impulses or indirectly by stimuli received through the special senses, is rich in enzymes and is highly acidic. Ivan Petrovich Pavlov, the Russian physiologist, originally demonstrated this method of gastric secretion in a now famous experiment in dogs.

The gastric phase is mediated by the vagus nerves and by the release of gastrin. The acidity of the gastric contents after a meal is buffered by food proteins so that overall it remains around pH3 for approximately 90 minutes. Acid continues to be secreted during the gastric phase in response to distension and to the peptides and amino acids that are liberated from food protein as digestion proceeds. The chemical action of free amino acids and peptides excites the liberation of gastrin from the antrum into the circulation. Thus, there are mechanical, chemical, and hormonal factors contributing to the gastric secretory response to eating. This phase continues until the food leaves the stomach.

The secretion of acid itself is an important inhibitor of gastrin release. If the pH of the antral contents falls below 2.5, gastrin is not released. Similarly, some of the hormones that are released from the small intestine by products of food digestion (especially fat), in particular glucagon and secretin, suppress acid secretion, although intact vagus nerves seem to be necessary for this to take place because the suppression of gastrin secretion is not observed after vagus nerves are severed (vagotomy).

The intestinal phase

The gastric chyme that enters the duodenum and jejunum continues to elicit acid secretion for many hours, although the amount of acid released diminishes progressively during the digestion and absorption processes in the small intestine. Some of the actions of the intestinal phase are due to gastrin released from the duodenum, but there is evidence that another hormonelike substance not yet characterized may be responsible. Finally, as certain amino acids and small peptides are infused into the circulation during this phase, they promote gastric acid secretion. It is possible, therefore, that the absorption of the products of protein digestion also may have a role in the intestinal phase. The phases of gastric secretion overlap, and there is an interrelation and some interdependence between the neural and humoral pathways.

Gastric digestion. The stomach is not primarily a digestive organ and is not essential to life. It is possible, for example, after total gastrectomy (the complete removal of the stomach) for a person to remain, or to become, obese because most of the digestion and absorption of food takes place in the intestines. The main functions of the stomach are to commence the digestion of carbohydrates and proteins, to convert the meal into chyme, and to discharge the chyme into the small intestine periodically as the physical and chemical condition of the mixture is rendered suitable for the next phase of digestion.

Salivary amylase works on food starch while the acidity of the mixture is low, around pH6, but ceases when the acidity of the mixture increases with greater acid secretion. The gastric pepsins account for only about 10 to 15 percent of the digestion of protein and are most active in the first hour of digestion. A lipase (fat-splitting enzyme) may be present in gastric juice, but it is not capable of digesting medium- and long-chain fatty acids, and the proportion of short-chain fatty acids in the food is small. Thus, little fat digestion proceeds in the stomach.

In addition to pepsin, the gastric juice of some mammals (*e.g.*, calves) contains another enzyme, rennin, which clumps milk proteins, thus taking them out of solution and making them more susceptible to the action of a proteolytic enzyme. Few animals other than mammals have such an enzyme. Although rennin aids digestion, it is not itself a digestive enzyme since it does not catalyze a hydrolytic reaction.

Gastric absorption. Although the stomach absorbs few of the products of digestion, it can absorb many other substances, including glucose and other simple sugars, amino acids, and some fat-soluble substances. Water moves freely from the gastric contents across the gastric mucosa into the blood. The net absorption of water from the stomach is small, however, because water moves just as easily from the blood across the gastric mucosa to the lumen of the stomach. About 60 percent of the "heavy" water (isotopic) that is placed in the stomach to trace its movements is absorbed into the blood in 30 minutes.

Alcohol and drugs

A number of alcohols, including ethyl alcohol, are readily absorbed from the stomach. The membranes of the cells that line the stomach are partly composed of lipids; hence items in the diet that are fat-soluble may penetrate them. The pH of the gastric contents also determines whether or not some substances are absorbed. At a low pH, for example, the environment is acidic and aspirin is absorbed from the stomach almost as rapidly as water, but as the pH of the stomach rises and the environment becomes more basic, aspirin is absorbed more slowly.

Nevertheless, the absorption of water and alcohol can be slowed if the stomach contains foodstuffs and especially fats, probably because gastric emptying is delayed by fats, and most water in any situation is absorbed from the jejunum. The absorption of drugs is influenced by the rate of gastric emptying, the presence of food or other drugs, the particular formulation of the drug, and the vehicle carrying it. The rate of emptying of the stomach depends upon the physical and chemical composition of the meal. Fluids empty more rapidly than solids, carbohydrates more rapidly than proteins, and proteins more rapidly than fats. Liquid meals that have the same osmotic pressure as blood (isotonic) empty more rapidly than hypotonic or hypertonic mixtures.

Small intestine. The small intestine is the principal digestive organ of the human alimentary canal. Three principal activities within the small intestine are especially adapted for its role in digestion: (1) its motor activity allows intraluminal contents to be mixed and transported; (2) its secretions into the lumen provide the necessary enzymes and other constituents essential for normal digestion; and (3) its absorptive capabilities are highly selective. The absorptive functions of the small intestine are made possible by the specialized structures of the intestinal mucosa that line the small intestine.

Motor activity. The contractions of the spiral muscle layers of the small intestine (the circular and the longitudinal muscles) are regulated by an electrical impulse that begins with the passage of calcium ions into the muscle cell. The depolarization of the muscle cell membranes, or an excess of positive charges on the inside of the cell, cause the myofibrils (the contracting components of the myofilaments that constitute the muscle tissues) to contract. The two spiral layers of muscle then contract, causing the motor activity that permits the mixing and transporting of the food in the small intestine. The rate of these contractions is governed by the rate of depolarization of the muscle cell membrane.

The part played by the hormones motilin and neurotensin (see below *Hormonal control of gastrointestinal function*) remains uncertain, although when they are infused intravenously in experimental studies, they promote

motor activity in both the small and large intestines. The basic neural control of the parasympathetic nervous system, which induces smooth muscle contraction, is exerted by the cholinergic neurons that secrete acetylcholine. The basic neuronal control of the sympathetic system, which induces relaxation of the smooth muscle wall, is exerted by the adrenergic neurons, which secrete epinephrine. In the myenteric plexus (a network of nerve fibres in the wall of the intestine) there are several other messenger substances capable of modulating smooth muscle activity, including somatostatin, serotonin (5-hydroxytryptamine), and the enkephalins. With at least seven such substances in and around the smooth muscle, there is some confusion as to their respective roles.

Types of motor activity. The primary purposes of the movements of the small intestine are to provide mixing and transport of intraluminal contents. Two types of motor activity have been recognized: segmenting contractions and peristaltic contractions. A characteristic of small intestine motility is the inherent ability of the smooth muscle constituting the wall of the intestine to contract spontaneously and rhythmically. This phenomenon is independent of any extrinsic nerve supply to the small intestine and creates pressure gradients from one adjacent segment of the intestine to another. The pressure gradients, in turn, are primarily responsible for transport within the small intestine.

Segmentation

The predominant motor action of the small intestine is the segmenting contraction, which is a localized circumferential contraction, principally of the circular muscle of the intestinal wall. Segmenting contractions mix, separate, and churn the intestinal chyme. The contraction involves only a short segment of the intestinal wall, less than one to two centimetres, and constricts the lumen, tending to divide its contents. There is a gradual decrease in the number of segmenting contractions as the chyme moves from the duodenum to the ileum. This has been described as the "gradient" of small intestine motility. Although segmenting contractions usually occur in an irregular manner, they can occur in a regular or rhythmic pattern and at a maximum rate for that particular site of the small intestine (rhythmic segmentation).

Rhythmic segmentation may occur only in a localized segment of small intestine, or it may occur in a progressive manner, with each subsequent segmenting contraction occurring slightly below the preceding one (progressive segmentation).

The duodenal pacemaker sends electrical impulses down the small intestine at a rate of 11 cycles per minute in the duodenum, gradually decreasing to eight cycles per minute in the ileum. These electrical changes are propagated down the small intestine in the longitudinal muscle layer of the wall of the small intestine. Superimposed upon the slow-wave electrical activity may be fast, spikelike electrical changes. This type of electrical activity originates in the circular muscle layer of the intestinal wall and occurs when the circular layer contracts to form a segmenting contraction. Between meals electrical activity is random, but it becomes intense when at 80- to 120-minute intervals a major migrating complex rolls along at six to eight centimetres per second.

Peristaltic contractions

A peristaltic contraction may be defined as an advancing ring, or wave, of contraction that passes along a segment of the gastrointestinal tract. It normally occurs only over a short segment (approximately every six centimetres) and moves at a rate of about one or two centimetres per minute. This type of motor activity in the small intestine is used primarily for transport of intraluminal contents downward, usually one segment at a time.

When some inflammatory condition of the small bowel exists, or when irritating substances are present in the intraluminal contents, a peristaltic contraction may travel over a considerable distance of the small intestine: this has been termed the peristaltic rush. Diarrhea due to common infections is frequently associated with peristaltic rushes. Most cathartics produce their diarrheic effect by irritating the intestinal mucosa or by increasing the contents, particularly with fluid.

Digestive secretions. There are many sources of digestive secretions into the small intestine. The gastric chyme that is emptied into the duodenum contains gastric secretions that will continue their digestive processes for a short time in the small intestine. One of the major sources of digestive secretion is the pancreas, a large gland that produces both digestive enzymes and hormones. The pancreas empties its secretions into the duodenum through the major pancreatic duct in the papilla of Vater and the accessory pancreatic duct a few centimetres away from it. Pancreatic juice contains enzymes that digest proteins, fats, and carbohydrates. Secretions of the liver are delivered to the duodenum by the common bile duct, via the gallbladder, and are received through the papilla of Vater. Secretion from the mucosal surface of the small intestine is minimal and usually is no more than a few millilitres per hour for any one segment of intestine.

Composition of intestinal secretions

The composition of the fluids secreted (the succus entericus) varies somewhat in different parts of the intestine. In the duodenum, for example, where the mucous Brunner's glands are located, the secretion contains more mucus. In general, the secretion of the small intestine is a thin, colourless or slightly straw-coloured fluid, containing flecks of mucus, water, inorganic salts, and organic material. The inorganic salts are those commonly present in body fluids, with the bicarbonate concentration higher than it is in blood. Aside from mucus, the organic matter consists of enzymes and cellular debris. Many enzymes have been reported to be present in intestinal secretions. These include a pepsin-like protease (from the duodenum only), an amylase, a lipase, at least two peptidases, sucrase, maltase, enterokinase, alkaline phosphatase, nucleophosphatases, and nucleocytases.

Secretions into the small intestine are controlled by nerves (vagus) and hormones. Except in the duodenum, the quantity of the fluid secreted is never great, even under conditions of stimulation. Stimulation of the vagus nerves in experimental animals causes a moderate secretion of juice from the duodenum and smaller amounts from the rest of the small intestine after a latent period of one to one and one-half hours. Stimulation of sympathetic nerves supplying the small intestine causes no secretion, but cutting the vagus nerves results in an increase in secretion. The most effective stimuli for the secretion of succus entericus are local mechanical or chemical stimulations of the intestinal mucous membrane. Such stimuli always are present in the intestine in the form of chyme and food particles. A hormone, enterocrinin, extracted from intestinal mucosa in humans, causes the secretion of juice from the intestinal mucosa in animals.

The three principal components in the human diet that require digestion are carbohydrates, proteins, and fats. Most of the digestive processes that solubilize these substances and reduce them to relatively simple organic compounds occur in the upper (proximal) small intestine. The plasma membrane over the microvilli is thicker and richer in protein and lipids than is the plasma membrane on the cells at the side and base of the villus. Fused to this brush border is the layer of glycoprotein that is known as the "fuzzy coat." The microvilli are important to both digestion and absorption. They elaborate the enzymes, disaccharidases and peptidase, that hydrolyze disaccharides and polypeptides to monosaccharides and to dipeptides and amino acids, respectively.

Microvilli

Molecular receptors for specific substances are found on the microvilli surfaces at different levels in the small intestine. This may account for the selective absorption of particular substances at particular sites, for example, intrinsic-factor-bound vitamin B_{12} in the terminal ileum. Such receptors may also explain the selective absorption of iron and calcium in the duodenum and upper jejunum. Furthermore, there are transport proteins in the microvillus membrane associated with the passage of sodium ions, D-glucose, and amino acids.

Actin is found in the core of the microvillus, and myosin is found in the brush border; because contractility is a function of these proteins, the microvilli have motor activity that presumably initiates the stirring and mixing actions within the lumen of the small intestine.

Certain nutrients are partly digested in the glycoprotein

fuzz. The products of this digestion penetrate the surface of the microvillus and pass into the interior of the enterocytes (intestinal epithelial cells) for further digestion, and ultimately they are transferred to the intercellular space.

Water and solutes pass through pores in the surface epithelium of the mucosa. The size of the pores is different in the ileum than in the jejunum; this difference accounts for the various rates of absorption of water at the two sites. The enterocytes are joined near their apex by a contact zone known as a "tight junction." These junctions are believed to have the pores that are closed in the resting state and dilated when absorption is required.

The tight junction

The movement of sodium and chloride is dependent to an extent on solvent drag; *i.e.*, solutes are caught up in a moving stream of water and the water movement causes an increased concentration of the solute on the side of the membrane from which the water originally had come. This gradient dictates the direction of solute movement. This is one mechanism for solute absorption, the other being active transport systems that move solutes across the cell membrane by the expenditure of energy.

Large intestine. Unlike that of the small intestine, the mucosa of the large intestine (colon) does not have villi. The mucosa of the large intestine is more glandular. Its surface is covered by tall columnar epithelial cells, and it has many crypts that are lined with mucous glands. The principal substances secreted by the colon are mucus, potassium, and bicarbonate. The mucus aids in lubricating the intestinal contents and facilitates their transport during mass movement contractions.

The primary function of the colon is to absorb water, sodium, and chloride from the chyme. Each day approximately 1.5 to two litres of fluid chyme pass through the ileocecal valve that separates the small and large intestines. The fluid is reduced by absorption in the colon to around 150 millilitres. The residual indigestible matter, together with sloughed-off mucosal cells, dead bacteria, and food residues not digested by bacteria, constitute the feces.

The rate of transit depends largely on the frequency and strength of the contractions of the smooth muscle in the colon wall. The inner layer of muscle is wound in a tight spiral around the colon, and contraction results in segmentation of the lumen and its contents: the spiral of the outer layer follows a loose undulating course, and contraction causes the contents of the colon to shift forward and backward. The bulk of the contents influences these muscular activities, in particular the amount of undigested fibrous material (roughage).

Other colonic functions include the excretion of surplus bicarbonate and potassium and the absorption of sodium and chloride. Thus, the colon has a role in maintaining the osmolality, or level of solutes, of the blood, which is partly dependent on the concentration of electrolytes. In vertebrates, these various functions are controlled by neural and hormonal mechanisms. The colon contains large numbers of bacteria, and a state of symbiosis exists (*i.e.*, disparate groups living together to mutual advantage). The bacteria synthesize niacin (nicotinic acid) and thiamine (vitamin B_1), two vitamins that are essential to several metabolic activities as well as to the function of the central nervous system. The bacteria also synthesize vitamin K, which is essential to the formation of the factors that are responsible for the clotting ability of the blood.

Symbiosis

Colonic motility. The electrical activity of the muscles of the colon is more complex than that of the small intestine. In the lower (distal) half of the colon, variations from the basic rhythmic movements are present 5 to 20 percent of the time, and in the rectum, variations are present 70 to 90 percent of the time. Slow-wave activity that produces contractions from the ascending colon to the descending colon occurs at the rate of 11 cycles per minute, and slow-wave activity in the sigmoid colon and rectum occurs at a rate of six cycles per minute. Electrical spike potentials, which indicate local contractions, migrate distally in the colon at the rate of four centimetres per second. Retrograde, or reverse, movements occur mainly in the upper (proximal) colon. The local contractions and the retrograde propulsions ensure mixing of the contents and good contact with the mucosa.

Neuronal and hormonal mechanisms combine to elicit colonic motility, but the proportionate contribution of each mechanism remains uncertain. Whereas the presence of fat in the colon stimulates motility, the presence of carbohydrate and protein do not. Unabsorbed bile salts and bile acids also increase motor activity. The peptide hormones gastrin and cholecystokinin stimulate colonic motility; secretin, glucagon, and vasoactive intestinal peptide suppress it. Mastication stimulates colonic motor activity.

The accumulating feces are stored in the descending and sigmoid sectors. Once or twice in 24 hours a mass peristaltic movement shifts the feces onward. The rectum is normally empty, but when it is filled with gas, liquids, or solids to the extent that the intraluminal pressure is raised to 15 to 20 centimetres of water, the impulse to defecate occurs.

The act of defecation is preceded by a voluntary effort, which, in turn, probably gives rise to stimuli that augment the visceral reflexes, although these originate primarily in the distension of the rectum. Centres that control defecation reflexes are found in the hypothalamus of the brain, in two regions of the spinal cord, and in the ganglionic plexus of the intestine. As the result of these reflexes, the internal anal sphincter relaxes.

Defecation reflexes

The mass contraction of the colon carries its contents into the pelvic colon, which in turn transfers them into the rectum, eventually to be evacuated by way of the anus. Thus, the entire distal colon from the splenic flexure to the anus may be emptied at one time. A prominent mechanical feature of defecation is the contraction of the longitudinal muscles of the distal and pelvic colon. The resulting shortening of the distal colon tends to elevate the pelvic colon and obliterates the angle that it normally makes with the rectum. The straightening and shortening of the passage facilitates evacuation.

Anatomy of defecation. The anal canal between the rectum and the body surface is three to four centimetres long. It is surrounded by the muscles constituting the internal and external sphincters. The inner ring of muscle is smooth in type and controlled by the autonomic system. The outer ring is a complex formed from the puborectal fibres of the levator and muscles and an external sphincter; both of these are striated muscle and can be relaxed or contracted voluntarily.

The musculus puborectalis forms a sling around the junction of the rectum with the anal canal, and it is maintained in a constant state of tension (tone). This results in an angulation of the lower rectum so that the lumen of the rectum and the lumen of the anal canal are not in continuity, a feature essential to continence. Continuity is restored between the lumina of the two sectors when the sling of muscle relaxes, and the angulation is overcome.

The anal canal is lined proximally with columnar mucosa innervated by the autonomic system and distally by squamous cells (a modification of skin) that are innervated by peripheral nerves.

Fibre. Fibre includes cellulose, hemicellulose, pectins, gums, and lignins, mostly polysaccharides built from five-carbon (furanose) or six-carbon (pyranose) rings. Fibres are polymers (compounds of high molecular weight formed by the linear combination of simpler repeating molecules, or monomers) with various linkage arrangements between the molecules. They defy the hydrolyzing enzymes of the small intestine. In the cecum and colon, however, the commensal bacteria break down the linkages.

Fibre can hold water either by binding to its surface or by trapping it in interstices in a spongelike manner. Fibre also has a capability for ion exchange and adsorption. Ion exchange is promoted by the electrical potential at the interface between the water and the fibre, which thus gives it the property of a colloid. As the bacterial enzymes break down the polysaccharides these cause disintegration of the matrix. Adsorption can take place on the surface of fibre as well. Drugs prescribed for the treatment of a disease may be adsorbed onto the fibre and become unavailable to the body. The adsorption of bile acids and other digestive products by fibre may not necessarily be disadvantageous.

(N.C.H./W.S.)

The hepatocyte

Liver. Hepatocytes occupy about 80 percent of the volume of the liver, and their cytoplasm (the area surrounding the nucleus) contains many mitochondria, which provide the energy needed for the many synthetic and metabolic functions of the liver cell. The cytoplasm also contains a series of long tubules, called the endoplasmic reticulum, which contains many enzymes essential to liver function. Some of the membranes of the endoplasmic reticulum appear granular, or rough, owing to the presence of ribosomes, which are responsible for forming specific polypeptide (protein) chains from single amino acids. The non-ribosomal, or smooth, endoplasmic reticulum is the site where cytochromes (combinations of heme from hemoglobin with various proteins) and certain enzymes undertake the important hepatic functions of drug and hormonal metabolism, cholesterol synthesis, and conjugation with carbohydrate moieties of bilirubin and other fat-soluble metabolic and foreign compounds, thereby making them soluble in water. The Golgi apparatus, a series of tubular structures between the endoplasmic reticulum and the canaliculus, acts as a transport station for newly made proteins and other hepatocytic products before they are conveyed to other parts of the cell or out of the cell entirely. Lysosomes, another important cytoplasmic constituent, are responsible for the intracellular storage of pigments, such as iron or copper, and for the digestion of certain contents, such as glycogen or foreign particles. The nucleus of the hepatocyte has no apparent functions that distinguish it from nuclei of other cells. The nucleus guides replication of the cell and transmits genetic material in the form of messenger ribonucleic acid (mRNA) from deoxyribonucleic acid (DNA) to organelles located in the cytoplasm.

Major functions of the liver

The major functions of the liver are to participate in the metabolism of protein, carbohydrate, and fat; to synthesize cholesterol and bile acids; to initiate the formation of bile; to engage in the transport of bilirubin; and to metabolize and transport certain drugs. Dietary amino acids from ingested protein are circulated to the hepatocytes of the liver, where they are either cycled into the production of specific human proteins, or used as a source of energy after having had the amino group removed (deamination) and converted into glucose through a process called gluconeogenesis. The ammonia released from amino acids in the process of gluconeogenesis is converted into urea only in the hepatocyte by way of a special enzyme-controlled metabolic process called the urea cycle. Except for the immunoglobulins (gamma globulins), which are produced in the spleen and lymphoid tissue, hepatocytes are the major source for the production of all blood proteins. These include albumin, proteins essential to the coagulation of blood, certain enzyme inhibitors such as $alpha_1$-antitrypsin, lipoproteins, and the transport proteins such as thyroxine-binding globulin, ceruloplasmin (copper), transferrin (iron), and transcobalamin (vitamin B_{12}). The stability of these proteins is quite variable; albumin, for example, has a half-life of more than 15 days, while some of the blood coagulation factors are functional for only seven hours.

The liver controls the transport and storage of energy-producing carbohydrates. Glucose, which is one of the two monosaccharide components of table sugar (sucrose) and milk sugar (lactose) and is the sole building block of dietary polysaccharides, such as starch, is combined with phosphate in the liver cell and either transported to peripheral tissues for metabolic purposes or stored in the hepatocyte as glycogen, a complex polysaccharide. Specific enzyme systems are present in the hepatocyte for these conversions, as well as for the translation of other dietary monosaccharides (fructose from sucrose and galactose from lactose) into glucose. The hepatocyte is also able to convert certain amino acids and products of glucose metabolism (pyruvate and lactate) into glucose through gluconeogenesis.

The liver also plays a central role in metabolizing fat by converting stored fatty acids to their energy-releasing form, acetylcoenzyme A (acetyl CoA), when hepatic glucose and glycogen stores are exhausted or unavailable for metabolic purposes (as in diabetic ketoacidosis). The liver also plays a role in the formation of storage fats (triglycerides) whenever dietary carbohydrates, protein, or fat exceeds the requirements of tissues for glucose or the needs of the liver for glycogen. The liver also synthesizes cell membrane components (phospholipids) and proteins (lipoproteins) that carry lipids (fats and cholesterol) in the blood.

Cholesterol

Cholesterol is a major factor in cell membrane structure, and it is essential to cellular survival. Cholesterol is a four-ringed sterol that is absorbed from the diet or synthesized from dietary acetyl CoA by the liver and the intestinal lining. Excess cholesterol is a major constituent of the bile that is produced in the liver and transmitted into the intestine. About half of the hepatic cholesterol is first converted into bile acids, which have the same sterol structure as cholesterol but contain three fewer carbon atoms and an acidic side chain. The rate of bile flow is controlled in part by the rate of bile acid secretion by the hepatocyte.

The hepatocyte also acts to transport certain water-insoluble products of metabolism and agents foreign to the body into the bile and urine. Bilirubin is the product of hemoglobin metabolism after the iron and protein fractions have been removed. Bilirubin is formed in the bone marrow and the lymphatic tissue and is carried to the liver after becoming bound to plasma albumin. It is released at the hepatocytic sinusoidal membrane and is transported to the smooth endoplasmic reticulum where, in an enzymatic system, it is conjugated with one or two molecules of glucuronic acid, thereby becoming soluble in water and excretable in bile. Similarly, many drugs that are normally insoluble in water are conjugated, or joined with other substances to detoxify them, in phase II reactions in hepatocytes after having been oxidized by cytoplasmic enzyme systems (phase I reactions). Small drug metabolites are excreted into the urine, while larger molecules leave the body through the bile and the feces.

Biliary tract. Aside from inorganic ions (sodium, potassium, calcium, magnesium, chloride, and bicarbonate), bile contains protein and bilirubin; the latter is responsible for its golden colour in dilute solutions and dark amber colour in concentrate. It is richest, however, in bile acids (derived from cholesterol in the hepatocyte), phospholipids (largely phosphatidyl choline, or lecithin), and cholesterol. Normally the cholesterol, which is not soluble in watery secretions, is carried in a colloidal solution in bile in the form of mixed aggregates of complexes containing bile acids and lecithin. In the absence of adequate amounts of lecithin and bile acids, cholesterol crystallizes.

Types of bile acid

The liver synthesizes two types of primary bile acid from cholesterol, called chenodeoxycholic acid and cholic acid. In the lower intestine, bacterial action removes one of the hydroxyl groups (dehydroxylation) from cholic acid, changing it to deoxycholic acid. This secondary bile acid appears in bile because it is absorbed from the intestine and recirculated to the liver. Chenodeoxycholic acid is also dehydroxylated in the intestine, becoming lithocholic acid, a small amount of which is also reabsorbed and appears in normal bile. Neither deoxycholate nor lithocholate appears to be an important factor in the incorporation of cholesterol micelles, or vesicles, in bile because they lack the important feature of carrying hydroxyl groups at both the C_3 and C_7 positions of the sterol nucleus.

The total bile acid pool at any one time measures about three grams, almost all of which is contained at rest in the gallbladder. It is maintained largely because about 95 percent of the bile acids entering the intestine from the biliary system are reabsorbed actively in the lower portion of the small intestine, so that only 0.2 to 0.6 gram of bile acids is lost daily. This loss can be replaced readily by the normal liver.

Bile is formed initially in the hepatocyte, and the rate of formation is dependent primarily on the rate at which bile acids are secreted into bile canaliculi. A portion of the flow of bile, however, is related to factors other than the secretion of bile acids. This flow appears to be dependent on the secretion of sodium from the hepatocyte and is also partially governed by the action of intestinal hormones such as secretin, cholecystokinin, and gastrin. In its passage through the biliary tract, hepatic bile is con-

centrated to as little as one-tenth of its original volume by the selective reabsorption of water, chloride, and bicarbonate. This concentration process takes place largely in the gallbladder, with the result that bile from this organ is much thicker in density and darker in colour (due to concentration of pigments) than is bile emerging from the liver. Distension of the duodenum, particularly by a meal containing fat, provokes the secretion of CCK, a hormone that causes contractions of the muscular layer in the wall of the gallbladder. Bile concentration is greatly reduced if the gallbladder is removed, but this effect apparently does not impede the primary digestive function of bile, which is to aid in the dispersion and digestion of fat in the lumen of the intestine.

Acinar cells

Pancreas. The acinar cells constitute more than 95 percent of the cellular population of the exocrine pancreas. Their membranes contain specific receptor sites for cholinergic (parasympathetic) and polypeptide (secretin and cholecystokinin) agonists. Acetylcholine and cholecystokinin (CCK) bind to parasympathetic receptor sites and, in the presence of calcium, cause marked enzymic secretion by acinar cells. Binding of vasoactive intestinal polypeptide (VIP) or secretin to acinar receptors activates the adenosine monophosphate shunt and causes increased production of bicarbonate, sodium, water, and enzymes by acinar cells and small ductal cells. Bicarbonate is secreted in exchange for chloride, and sodium is exchanged for hydrogen, with a resultant increased acidity of the blood leaving the actively secreting pancreas.

In the acinar cell, almost all enzymatic proteins are synthesized on ribosomes from amino acids carried to the pancreas by the bloodstream. The enzyme precursors are conjugated in the Golgi apparatus, and then concentrated into membrane-wrapped cytoplasmic zymogen granules. Upon stimulation with CCK or acetylcholine, these zymogen granules migrate to the apex of the acinar cell where they are extruded into the central ductal lumen. These stimulants also increase the synthesis of zymogen granules. In the absence of CCK and acetylcholine, as in fasting subjects or in patients being fed intravenously, the synthesis of zymogen by the acinar cells is markedly reduced. Pancreatic atrophy also occurs after removal of the pituitary gland, probably due to the absence of growth hormone. Thus CCK, acetylcholine, and growth hormone are pancreatotrophic hormones. The pancreas itself also appears to secrete an as yet unidentified hormone that is trophic, or nutritive, to the liver.

Pancreatic enzymes

Acinar cells produce a great variety of digestive proteins, or enzymes, involved principally with the degradation in the intestine of dietary proteins (proteases), fats (lipases), and carbohydrates (amylases). Other protein secretions include a trypsin inhibitor, a so-called stone protein that keeps calcium in solution, and various serum proteins, including albumin and immunoglobulins. Proteases are of two types, endopeptidases and exopeptidases. The former, including trypsinogen, chymotrypsinogen, and proelastase, split food proteins at internal amino acid linkages, while the latter, including procarboxypeptidases A and B and kallikreinogen, cleave terminal chain residues from polypeptides (proteins). Each of these proteases is secreted in an inactive, or precursor, form. Trypsinogen is activated in the intestine by enterokinase, an enzyme liberated from duodenal lining cells by the interaction of bile acids and CCK. This activation of trypsinogen to trypsin is brought about by the cleavage from it of six terminal amino acid residues. The other proteases are activated by free trypsin. The net effect of these proteases is to reduce dietary proteins to small polypeptides (two to six amino acid chains) and to single amino acids. Lipases include phospholipase, esterase, colipase, and lipase, which function to reduce neutral fats (triglycerides) and free fatty acids and monoglycerides, to hydrolyze dietary phospholipids, and to reduce long-chain fatty acids. Lipases require the presence of bile acids in the intestinal lumen for the formation of micellar solutions of fat prior to optimal digestion. There are at least six varieties of amylase in pancreatic juice whose function is to hydrolyze complex carbohydrates (polysaccharides) to disaccharides and trisaccharides.

Pancreatic secretion is mediated by stimulants such as secretin, a hormone released from the duodenal wall by the physiological introduction of gastric acid into the duodenum, and CCK, which is released by the presence of dietary fat and amino acids, as well as by gastric hydrochloric acid. Stimulation of the vagus nerve by hunger also releases acetylcholine in the acinar milieu and leads to enzymatic secretion. The flow induced by secretin is a high-volume, bicarbonate-and-water mixture that also contains moderate amounts of enzymes. The flow induced by CCK is thick, low in bicarbonate and highly concentrated in enzymes. (H.J.Dw.)

Features of the gastrointestinal tract

GENERAL FEATURES OF DIGESTION AND ABSORPTION

Methods of absorption

There are four means by which digestive products are absorbed: active transport, passive diffusion, facilitated diffusion, and endocytosis.

Active transport involves the movement of a substance across the membrane of the absorbing cell against an electrical or chemical gradient. It is carrier-mediated, that is, the substance is temporarily bound to another substance that transports it across the cell membrane, where it is released. The process requires energy and is at risk of competitive inhibition by other substances; that is, other substances with a similar molecular structure can compete for the binding site on the carrier. Passive diffusion requires neither energy nor carrier; the substance merely passes along a simple concentration gradient from an area of high concentration of the substance to an area of low concentration, until a state of equilibrium exists on either side of the membrane. Facilitated diffusion also requires no energy, but it involves a carrier, or protein molecule located on the outside of the cell membrane that binds the substance and carries it into the cell. The carrier may be competitively inhibited. Endocytosis takes place when the material to be absorbed, on reaching the cell membrane, is enfolded into it. That part is then pinched off into the cell interior. This process is similar to phagocytosis.

Absorption of all food by the small intestine occurs principally in the jejunum; however, the duodenum, although the shortest portion of the small intestine, has an extremely important role. The duodenum receives not only chyme saturated with gastric acid, but pancreatic and liver secretions as well. It is in the duodenum that the intestinal contents are rendered isotonic with the blood plasma; *i.e.*, the pressures and volumes of the intestinal contents are the same as those of the blood plasma, so that the cells on either side of the barrier will neither gain nor lose water.

The bicarbonate secreted by the pancreas neutralizes the acid secreted by the stomach. This brings the intestinal contents to the optimal pH, allowing the various enzymes to act on their substrates at peak efficiency. A number of important gastrointestinal hormones regulate gastric emptying, gastric secretion, pancreatic secretion, and contraction of the gallbladder. These hormones, along with neural impulses from the autonomic nervous system, provide for autoregulatory mechanisms for normal digestive processes.

Electrolytes and water

Most salts and minerals, as well as water, are readily absorbed from all portions of the small intestine. Twelve to 25 grams of sodium are present in the average daily diet. The sodium is absorbed by an active process, and the necessary metabolic energy is provided by the epithelial cells of the mucosa of the small intestine. Sodium is moved from the lumen of the intestine across the mucosa against a concentration gradient (*i.e.*, a progressive increase in the concentration of sodium) and an electrochemical gradient (*i.e.*, a gradual increase in the concentration of charged ions). Sodium ions are absorbed more readily from the jejunum than from other parts of the small intestine.

Potassium is absorbed at about 5 percent of the rate of sodium. It is thought that potassium moves across the intestinal mucosa passively or by facilitated diffusion as a consequence of water absorption. Chloride is readily absorbed in the small intestine and probably takes place as a consequence of sodium absorption. The absorption of water appears to be secondary to the absorption of electrolytes (substances that dissociate into ions in a solution). Water absorption occurs throughout the small intestine,

though chiefly in the jejunum. The upper small intestine absorbs approximately 95 percent of a 50-gram sample within 10 minutes. Water moves freely across the intestinal mucosa both ways, but tends to move in the direction of the hypertonic solution (the solution into which a net flow of water occurs), and away from the hypotonic solution (one from which a net flow of water occurs). Thus, if the contents of the lumen are hypotonic, water moves rapidly from the lumen to the blood. If the contents of the intestinal lumen are hypertonic, water moves more rapidly from the blood into the lumen. This two-way movement of water tends to maintain the intestinal contents in an isotonic state.

SPECIFIC FEATURES OF DIGESTION AND ABSORPTION

Carbohydrates. Carbohydrates are absorbed as monosaccharides (simple sugars that cannot be further broken down by hydrolysis) or disaccharides (carbohydrates that can be hydrolyzed to two monosaccharides). The absorption of glucose and galactose is dependent on the presence of sodium and uses active transport to move against a concentration gradient. Amylose, a starch polysaccharide (a carbohydrate that contains many monosaccharides), accounts for 20 percent of dietary carbohydrate. It consists of a straight chain of glucose (sugar) molecules bound to their neighbours by oxygen links. The bulk of the starch is amylopectin, which has a branch chain linked in after every 25 molecules of glucose on the main chain.

Digestion of starch

Only a small amount of starch is digested by salivary amylase; most is rapidly digested in the duodenum by pancreatic amylase. But even this enzyme has little effect on the branch chains of amylopectin, and even less on the linkages in cellulose molecules. This accounts for the inability of humans to break down cellulose. Pancreatic amylase changes amylose to maltose (a disaccharide) and the amylopectins to dextrins.

In the brush border (comprising ultrafine microvilli) and the surface membrane of the epithelial enterocytes are the disaccharidase enzymes, lactase, maltase, sucrase, and trehalase, which hydrolyze maltose and the dextrins to the monosaccharides glucose, galactose, and fructose.

Fructose appears to be absorbed by simple diffusion, but glucose and galactose are transported by an energy-using process, probably binding it to a specific protein carrier with attached sodium ions; the sugar is released inside the enterocyte, sodium is pumped out, and the sugars then diffuse into the circulation down a concentration gradient.

Proteins. The digestion of protein entails breaking the complex molecule first into peptides, each having a number of amino acids, and second, into individual amino acids. The pepsins are enzymes secreted by the stomach in the presence of acid that breaks down proteins (proteolysis). The trypsins (proteolytic enzymes secreted by the pancreas) are much more powerful than pepsins so that the greater part of protein digestion occurs in the duodenum and upper jejunum. Hence, even after total removal of the stomach, protein digestion usually is not impaired.

Pancreatic secretion contains inactive protease precursors that become enzymatically active after being mixed with another enzyme, enterokinase, which is secreted from the microvillous component of the enterocytes in the duodenal and jejunal mucosa. Enterokinase converts an inactive precursor, trypsinogen, to trypsin, which activates the other pancreatic proteases, including chymotrypsin and elastase. Trypsin, chymotrypsin, and elastase are known as endopeptidases and are responsible for the initial breakdown of the protein chains to peptides by hydrolysis. The next step, the breakdown of these peptides to smaller molecules and then to individual amino acids is brought about by the enzymic activity of carboxypeptidases, which are also secreted by the pancreas.

Endopeptidases

Peptidase activity commences outside the enterocytes (in the mucus and brush border) and continues inside the cell. There appears to be a different peptidase for each stage of the breakdown of protein to amino acids. Likewise, the transport of different peptides involves different mechanisms. Dipeptides (peptides that release two amino acids on hydrolysis) and tripeptides (peptides that release three amino acids) are moved from the surface brush border into the cell by an energy-requiring process involving a carrier protein. Small peptides with few amino acids are absorbed directly as such. The greater part of the breakdown of peptides to amino acids takes place within the enterocyte. Curiously, small peptides are absorbed more rapidly than amino acids, and indeed the precise details of the mechanism for absorption of amino acids is largely unknown. It is known that some amino acids have a specific individual transport system while others share one.

Transport of peptides

Amino acids may be classified into groups, depending upon their optical rotatory characteristics (*i.e.*, whether they rotate polarized light to the left, or levo; or to the right, or dextro) and in terms of reactivity, or acidity (pH). Levorotatory amino acids are absorbed extremely rapidly—much more rapidly than are dextrorotatory amino acids. In fact, levorotatory amino acids are absorbed almost as quickly as they are released from protein or peptide. Neutral amino acids have certain structural requirements for active transport, and if these specific structural arrangements are disturbed, active transport will not occur. Basic amino acids, which have a pH above 7, are transported at about 5 to 10 percent of the rate of neutral levorotatory amino acids.

Fats. Almost all dietary fat is stored as triglycerides. Solubility in water is necessary in order for fat to be transferred from the lumen of the intestine to the absorptive cells. Many factors, such as the length of the fatty acid chains of the triglycerides, play an important role in determining this solubility. Triglycerides have three long chains of fatty acids (LCFA) attached to a glycerol framework, and they are insoluble in water. The remainder are medium-chain triglycerides (MCT), which can be absorbed intact by the mucosa of the small intestine. Lipase acts on MCT's to free medium-chain fatty acids (MCFA), which are more soluble in water than the LCFA's and move quickly through the cells and pass into the portal circulation and then to the liver. Because MCFA's are more soluble in water, and because MCT's are absorbed by the mucosa, the addition of MCT's to the diet when disease or surgery impair enzyme hydrolysis of fat guarantees that some fat will be available for nutrition.

Pancreatic lipase

Long-chain fatty acids attached to the triglycerides are attacked by the pancreatic enzyme lipase. Two of the three fatty acid chains are split off, leaving one attached to the glycerol (forming a monoglyceride). In the presence of excess levels of bile salts, however, the lipolytic activity of pancreatic lipase is inhibited. Another pancreatic enzyme, colipase, binds to the bile salts, leaving lipase available to attack the triglycerides. The monoglycerides that result from these splitting processes combine into a complex called a micelle. The micelle, because of its physiochemical properties, permits fat components to be soluble in water. Because bile salts have a hydrophobic, or water-repelling region, and a hydrophilic, or water-attracting region, the micelle is formed with bile salts arranged around the outside with hydrophobic ends facing inside, and hydrophobic fatty acids, monoglycerides, phospholipids, and cholesterol, as well as the fat-soluble vitamins A, D, E, and K, in the centre.

There is a layer of fluid overlying the surface cells of the mucosa of the small intestine known as the "unstirred" layer. It is across this layer that the micelles must pass to reach the cell membranes. The rate of diffusion through the unstirred layer is determined by the thickness of the layer and the gradient in concentrations of the various elements of the transport system from the lumen of the intestine to the cell membrane. Underneath the unstirred layer is another layer known as the fuzz, which mainly comprises mucus. Beneath the fuzz is the brush border on the surface of the cell membrane. It has a double layer of lipid which is easily penetrated by the fatty acids and monoglycerides that are soluble in lipids. Once the micelle has passed through the fuzz and the brush border, it has entered the cells of the tissues that line the intestine. The micelle disintegrates, the bile salts diffuse back into the lumen, and a carrier protein picks up the fatty acids and the monoglycerides and transports them to the endoplasmic reticulum in the cell interior. The endoplasmic reticulum is a tubular structure rich in enzymes. At this site the

Intracellular events

triglyceride is synthesized again under the influence of an enzyme catalyst called acyltransferase.

The triglycerides pass to the membrane of another tubular structure, known as the Golgi apparatus, where they are packaged into vesicles (chylomicrons). These vesicles are spheres with an outer coating of phospholipids and a small amount of apoprotein while the interior is entirely triglyceride except for a small quantity of cholesterol. The chylomicrons migrate to the cell membrane, pass through it, and are attracted into the fine branches of the lymphatic system, the lacteals, and from there pass to the thoracic duct. The whole process of absorption, from the formation of micelles to the movement out of the cells and into the lacteals, takes between 10 and 15 minutes.

The medium-chain triglycerides are broken down to medium-chain fatty acids by pancreatic lipase. Medium-chain fatty acids are soluble in water and readily enter the micelles. Ultimately, after moving across the membrane of the enterocyte, they pass into the capillary tributaries of the portal vein and then to the liver.

Fat-soluble vitamins. Fat-soluble vitamins pass with the chylomicrons into the lymphatic system. Vitamin A, first presenting as a precursor, beta-carotene, is cleaved to form retinol, which is then recombined with fatty acids before entering the chylomicron. Vitamins D and D_3 diffuse passively into the chylomicron. The absence of bile salts from the intestine, which occurs in jaundice due to obstruction of the biliary tract, severely impairs vitamin K absorption and blood clotting, with risk of hemorrhage. Vitamin E, a mixture of oils known as tocopherols, is present in hen eggs and is synthesized by such plants as soybeans, corn (maize), wheat, and palms. It passes through the enterocyte with the other lipids of the micelle and is ultimately stored in the liver. The average diet contains 15 to 25 milligrams of alpha-tocopherol per day, which covers recommended requirements.

Calcium. Calcium is required for the construction of bone; it forms part of the substance cementing together the walls of adjacent cells; and it is vital in the responsiveness to stimuli of muscle and nerve cells, which determines their excitability. The main sources of calcium are milk and milk products, meat, in which it is bound to proteins; and vegetables, in which it is bound to phytates (phytic acid) and oxalates (the salt of oxalic acid).

Sources of calcium

The absorption of calcium is influenced by conditions within the lumen of the small intestine. The acid secretion from the stomach converts the calcium to a salt, which is absorbed in the jejunum. Unabsorbed calcium is precipitated in the ileum and is excreted in the feces. Lactose, the sugar of milk, aids calcium absorption, whereas excess fatty acid and high concentrations of magnesium and oxalates interfere with it.

Calcium is absorbed across the brush border of the enterocyte cell membrane by a mechanism that requires energy. Vitamin D is essential to this process, and when deficient, the active transport of calcium stops. Other influences on absorption of calcium are the activity of the parathyroid hormone (parathormone) and of growth hormone from the pituitary gland. An average diet contains 1,200 milligrams of calcium, one-third of which is absorbed. In the passage of the blood through the kidney, 99 percent of the circulating calcium is reabsorbed. Thus, in kidney failure as well as in jejunal malabsorption states, excessive losses of calcium occur. In calcium deficiency, calcium is resorbed from the bone, thereby weakening and softening the skeletal structure.

Magnesium. An average day's diet contains around 300 milligrams of magnesium, of which two-thirds is absorbed. Half of the absorbed magnesium is excreted by the kidneys, which can regulate the amount within a range of one to 150 millimoles per day. This control is subject to the influences of the parathyroid hormone, parathormone, and the thyroid hormone calcitotonin. Magnesium is important to neuromuscular transmission. It is also an important cofactor in the enzymic processes that form the matrix of bone and in the synthesis of nucleic acid. Magnesium deficiency can result from the overuse of diuretics and from chronic renal failure, chronic alcoholism, uncontrolled diabetes mellitus, and severe intestinal malabsorption.

Magnesium has an inverse relationship with calcium. Thus, if food is deficient in magnesium, more of the calcium in the food is absorbed. If the blood level of magnesium is low, calcium is mobilized from bone. The treatment of hypocalcemia due to malabsorption includes administration of magnesium supplements.

Hematinics. Hematinics are substances that are essential to the proper formation of the components of blood. They include folic acid, vitamin B_{12}, iron, and vitamin D.

Folic acid. Folic acid (pteroylglutamic acid) is necessary to the synthesis of nucleic acids and to cell replication. In deficiency of folic acid, maturation of red blood cells (erythrocytes) is impaired. Folates are synthesized by bacteria and plants and are hydrolyzed to folic acid in the intestine. Milk and fruit are the main sources of folic acid, providing on average 500 micrograms daily, which is four times the normal requirement. The liver stores amounts up to 5,000 micrograms.

The hydrolysis of the folates, a necessary step to absorption, takes place on the brush borders of jejunal enterocytes and is completed on lysosomes (structures within the cell that contain various hydrolytic enzymes and are part of the intracellular digestive system). When hydrolysis of folates is disturbed, anemia develops. This process is interfered with by certain drugs, especially phenytoin, used in the management of epilepsy, and by the long-term use of sulfonamides in the suppression of disease. A methyl group is added to pteroylglutamic acid in the enterohepatic circulation (methylation) in the liver and is excreted in the bile. Approximately 100 micrograms are utilized each day. The method of absorption is uncertain.

Hydrolysis of folates

Vitamin B_{12}. Vitamin B_{12}, also called cobalamin because it contains cobalt, is essential to the formation of blood cells. It is a coenzyme that assists the enzymes responsible for moving folate into the cell interior. Vitamin B_{12} is a product of bacterial metabolism and enters animal tissue from this source. Although bacteria in the human colon also produce vitamin B_{12}, it cannot be absorbed at that site. Vitamin B_{12} is in a bound form in food and is liberated by proteolytic activity in the stomach and small intestine. It then binds with intrinsic factor (IF), a glycoprotein elaborated in humans by the same parietal cells that form hydrochloric acid. In some species the IF is produced in the chief cells. Intrinsic factor is essential to transport, and the B_{12} protein complex, known as transcobalamin II, is necessary to movement of the vitamin from the intestine to the rest of the body. Once the IF is attached, further proteolytic digestion of the bound vitamin is prevented. Absorption is confined to the distal 100 centimetres of ileum, especially the last 20 centimetres, where the complex binds to receptors in the brush border of the enterocytes. The process is slow; it takes three hours from its presentation in food to its appearance in the peripheral blood via the enterohepatic circulation and hepatic veins. The daily requirement of vitamin B_{12} is one microgram; however, five to 10 micrograms circulate via the ileum and liver, and the liver stores up to 5,000 micrograms. A small amount (1.5 percent) of the vitamin can be absorbed in the small intestine by diffusion.

Iron. Iron is necessary for the synthesis of hemoglobin, the oxygen-carrying compound of the red blood cells. It also has an important role as a cofactor in intracellular metabolism. The main dietary sources are meat, eggs, nuts, and seeds, and more iron is absorbed from meat (20 percent) than from vegetables (5 percent). The average daily diet contains approximately 20 milligrams of iron, and humans are unable to excrete iron that has been absorbed in excess of the daily requirement of one milligram.

Dietary sources of iron

The acid in the stomach prevents the formation of insoluble complexes, as does vitamin C. Some amino acids from dietary protein stabilize the iron in complexes of low molecular weight. Phosphates and phytates of vegetable origin, some food additives, and the inhibition of acid secretion impede the absorption of iron. Iron is almost wholly absorbed in the duodenum by a process that involves metabolic activity requiring energy. Most of the iron remains trapped in the surface enterocytes and is lost when the cells die and fall off into the intestine. The amount of iron lost seems to be related in some way to the state

of the body's iron stores, although this can be overcome if very large doses of iron are taken orally. Alcohol in the stomach and duodenum increases the rate of absorption. Transport of the iron from the enterocyte is achieved by binding to a carrier, a plasma protein called transferrin. From the intestine, it passes into the portal circulation and the liver. When the loss of iron is increased, as in excessive menstruation and in bleeding disorders, the rate of absorption is stepped up from less than one milligram per day to 1.5 milligrams or more.

Vitamin D. Vitamin D is essentially a hormone and is available from two sources. First, under the influence of photosynthesis made possible by ultraviolet rays from the Sun, a sterol compound from the liver (dehydrocholesterol) is converted to vitamin D_3. This supplies enough vitamin D_3 for human needs. In the absence of contact between sunlight and skin, dietary supplements become necessary. Fish liver oil, eggs, liver, fortified bread, and milk are the main sources. Deficiency of vitamin D occurs when there is lack of sunlight and inadequate vitamin D in the diet. It may also result from disease or after resection of the small intestine, which may cause malabsorption. In these circumstances, softening of bone (osteomalacia) and rickets occur.

Deficiency of vitamin D

In the jejunum, vitamin D is incorporated along with bile salts and fatty acids into the micelles, and subsequently, as the provitamin D_1, vitamin D is absorbed in the ileum and then passes into the circulation via the portal vein. A specific blood-borne protein, an alpha-1–globulin, carries it to the liver, where the process of chemical change to the active hormone begins by hydroxylation to cholecalciferol. The derivatives are conveyed from the liver to various tissues, including the skin, bone, and parathyroid glands. In the intestine, vitamin D influences the permeability of the brush borders of the enterocytes to calcium.

Intestinal gas. The movement of gas through the intestines produces the gurgling sounds known as borborygmi. In the resting state, there are usually about 200 millilitres of gas in the gastrointestinal tract. Its composition varies: between 20 and 90 percent is nitrogen, up to 10 percent is oxygen, up to 50 percent is hydrogen, up to 10 percent methane, and between 10 and 30 percent is carbon dioxide. Most of the air we swallow, while talking and eating in particular, is either regurgitated (as in belching) or is absorbed in the stomach.

Although some of the carbon dioxide in the small intestine is due to the interaction of hydrogen ions of gastric acid with bicarbonate, some is generated in the jejunum by the degradation of dietary triglycerides to fatty acids. High levels of carbon dioxide in rectal flatus reflect bacterial activity in the colon. Methane cannot be produced by any human cell and is entirely the result of bacteria acting on fermentable dietary residues in the colon, although there appears to be a familial factor involved in this as not everyone can generate methane. How much of this is genetic and how much is environmental is not known. In the colon, bacterial production of hydrogen is markedly elevated when the diet contains an excess of vegetable saccharides. This is particularly noticeable after a meal of baked beans, for example. Gas is more often responsible for the buoyancy of stools than is excessive residual fat in malabsorption states.

The gradient between the partial pressures (or the pressure exerted by each gas in a mixture of gases) of particular gases in the intestinal lumen and the partial pressures of gases in the circulating blood determines the direction of movement of gases. Thus, because oxygen tends to be in low pressure in the colon, it diffuses out from the blood into the intestine. The diffusion of nitrogen from the blood into the intestine occurs because a gradient is established by carbon dioxide, methane, and hydrogen that result from the metabolic activities of the commensal bacteria; the partial pressure contributed by nitrogen in the colon is lowered, stimulating nitrogen to enter the intestine from the blood.

Direction of gas movement

Anxiety induces frequent swallowing of air with consequent belching or increased rectal flatus. The action of sighing sucks air into the stomach as it creates a negative pressure (or one that is less than that of the atmosphere) in the thoracic cage. Fast eaters develop uncomfortable gaseous distension of the abdomen, and swallowed air may reach the anus within 15 to 30 minutes. Rectal gas in air-swallowers contains a high proportion of nitrogen, whereas in excess flatus due to bacterial metabolism of food residues, the gas has a high content of hydrogen and carbon dioxide.

In areas where lactase, the enzyme that breaks down lactose (milk sugar), is missing from the group of disaccharidases of the small intestine, lactose passes into the colon undigested. In the lactase-deficient subject, the unhydrolyzed lactose enters the colon, where the amount of lactose normally present in a glass of milk is capable of liberating, after bacterial fermentation, the equivalent of two cups (500 millilitres) of gas (hydrogen), about 15 percent of which diffuses back into the blood, with the rest passing as flatus.

Hydrogen generated in the colon is partly absorbed, passes in the circulating blood to the lungs, and diffuses into the respiratory passages, where its presence can be easily determined. The time taken for hydrogen to appear in the breath after ingestion of a standard load of glucose or lactose is used to determine whether the upper area of the gastrointestinal tract is colonized by bacteria. Hydrogen that appears within 30 minutes of the ingestion of the sugar load suggests heavy colonization of the small intestine.

Hormones of the gastrointestinal tract. Control of the activity of the specialized cells in the digestive system that are concerned with motor and secretory functions depends upon signals received at their cell membranes. These sig-

Hormones of the Digestive Tract*

notation of cell type	product	location
A	glucagon	pancreas
B	insulin	pancreas
D	somatostatin	body, antrum, duodenum, jejunum, ileum, colon, pancreas
G	gastrin	antrum, duodenum
I	cholecystokinin	duodenum, jejunum, ileum
K	gastric inhibitory peptide	duodenum, jejunum, ileum
L	intestinal glucagon	ileum, colon
Mo	motilin	duodenum, jejunum

Messenger molecules

nals originate in either endocrine or nerve cells and are carried to the target cell by amino or peptide "messenger" molecules. When secreted, these substances either diffuse into the tissue spaces around the cells and affect target cells in the vicinity or are taken up in the circulating blood and delivered to target cells some distance away. In both circumstances, the messengers are hormones, but those exerting their effect locally are called paracrine; those exerting their effect at a distance are called endocrine.

Peptides are composed of a number of amino acids strung together in a chain. The amino acids occur in an ordered sequence that is peculiar to each peptide. The biological activity of the peptide (*i.e.*, the ability to stimulate the target cells) may reside in only a fraction of the chain, for example, in a four- or five-amino-acid sequence. In other instances, the entire chain must be intact to achieve this purpose. For example, dispersed throughout the whole gastrointestinal tract are the delta (D) cells (see Table), which produce a hormone known as somatostatin. This hormone has inhibiting effects on the production of acid in the stomach, the motor activity of the intestine, and the release of digestive enzymes from the pancreas. These effects are achieved by local diffusion of somatostatin from the delta (D) cells in the vicinity of the target tissue; there is no evidence that somatostatin circulates in the blood. On the other hand, gastrin, a hormone produced by the granular enterochromaffin (G) cells in the mucosa of the gastric antrum, is secreted into the blood.

Gastrin also exemplifies the biological capability of a fraction of the molecule. These fractions have a molecular structure that fits the receptor site on the membrane of the target cell and therefore can initiate the intracellular events in the production of the acid. The G cells produce a messenger peptide with 34 amino acids in sequence and another with only 17 in the chain. The shorter molecule is more potent. The chain can be cleaved to only four amino acids (the tetrapeptide), however, and providing the sequence remains the same as in the parent molecule and the fragment is the one at the amino terminal of the whole molecule, the cleaved amino acid chain retains biological activity, although it is less potent than the larger molecules of gastrin.

Immunocytochemistry

The identification of the gastrointestinal hormones and their cells of origin has been facilitated by the advent of immunocytochemistry, for both light and electron microscopy. In this process, the peptide under study is injected into an animal. Because this is "foreign" protein, or antigen, it stimulates the formation of specific antibodies that fight a particular peptide. In due course the antibodies are harvested from the animal's blood. The antibodies are then "labeled" by attaching a fluorescent dye (for viewing by ordinary light microscopy), or gold (for viewing by electron microscopy). The tissue under examination is treated with this immunochemical complex, and the antibody seeks out the original peptide, or antigen, latches onto it, and deposits the fluorescein or gold at the site. The cell and its contents are then available for detailed microscopy.

Immunocytochemistry made possible the recognition that G cells of the antrum of the stomach mainly produce the 17-amino-acid variety of gastrin, while those in the duodenum and jejunum mainly produce the 34-amino-acid variety. Through the application of such methods, certain messenger peptides have been found to originate not in endocrine cells but in neural elements within the gastrointestinal tract, to be released during electrical discharge within the nerves. For example, vasoactive intestinal peptide (VIP) released from nerve terminals in the brain also is present in abundance in the nervous structures of the gut, including the submucosal and myenteric nerve plexuses. Occasionally VIP coexists with acetylcholine, the messenger molecule of the autonomic parasympathetic nervous system. The discharge of VIP brings about receptive relaxation of the esophageal and pyloric sphincters, modulates the long peristaltic movements in the intestine, and influences the secretion of electrolytes from the mucosa of the small intestine.

Eighteen different endocrine cells can be identified within the gastrointestinal tract, but it is probable that several of these and their particular peptides are evolutionary vestiges that functioned in other stages of human development, while others may represent different stages of maturation of the same endocrine cell.

Peptides that bind with target cell receptors and stimulate the cell to react are known as agonists. Others that fit the receptor but do not initiate intracellular events are known as antagonists. The ability of antagonists to occupy receptors and thereby deny access to an agonist is the basis of the treatment of peptic ulcer disease with histamine (H_2) receptor blockers. By occupying the receptors on the parietal cells, antagonists deny histamine the opportunity to initiate the production of hydrochloric acid.

Antagonists

It should be noted that similar events stimulate or suppress the production of the messenger peptides in their endocrine or neural cell of origin. For example, the discharge of granules of gastrin from the G cells occurs when a meal is taken. While the concentration of hydrogen ions (the acidity) remains low because of the buffering effect of the food, the release of gastrin continues. As digestion proceeds and the stomach begins to empty, however, the acidity increases because of the diminishing neutralizing effect of the food. When the contents of the stomach in contact with the mucosa of the antrum reach a certain level of acidity (pH of 2.5 or less), the release of gastrin stops. Failure of this mechanism leads to inappropriate secretion of acid when the stomach is empty of food and may cause peptic ulcers in the duodenum. Some endocrine cells have microvilli on their surface that project into the lumen of the gland or into the main channel of the stomach or intestine. These cells probably have an ability to "sample" continuously the lumenal contents in their vicinity. This could be the basis of the information pertinent to the behaviour of the endocrine cell.

When production and secretion of a peptide hormone is excessive, it induces an increase in the number of the target cells and may increase the size of the individual cells. This is known as trophism and is similar to the increase in size of skeletal muscle in response to appropriate exercise (work hypertrophy). Such trophism is observed in certain disease states that involve the gastrointestinal hormones. Thus, when gastrin is secreted into the blood by a tumour of G cells (gastrinoma) of the pancreas, it is a continuous process because there is no mechanism at that site to inhibit the secretion: this brings about a massive increase in the number of parietal cells in the stomach and an overproduction of acid. This overwhelms the defenses of the mucosa of the upper gastrointestinal tract against autodigestion and results in intractable and complicated peptic ulceration.

Characteristics of gastrointestinal hormones

The individual endocrine cells and their products are listed in the Table. The characteristics of the gastrointestinal hormones are summarized below.

Insulin. Insulin is secreted by the beta (B) cells of the pancreas in response to a rise in plasma glucose concentration and a fall in glucagon level. It disperses carbohydrate (glucose) to stores in muscle and adipose (fatty) tissue. Insulin is used in the treatment of diabetes mellitus.

Glucagon. A hormone that is elaborated by alpha (A) cells, which are widely distributed in the alimentary tract, glucagon may stimulate the secretion of water and electrolytes by the mucosa of the small intestine. Otherwise, glucagon is an inhibiting hormone. It inhibits the production of gastric and pancreatic secretions—in particular the secretion of insulin—and the contractions of smooth muscle. It is sometimes used in radiology and endoscopy to improve visualization of the duodenum. Glucagon also is used in the treatment of conditions in which the level of sugar in the blood is lowered.

Somatostatin. Somatostatin is a peptide secreted by the delta (D) cells in response to eating, especially when fat enters the duodenum. It is an inhibitory modulator of the secretion of acid and pepsin and the release of gastrin, insulin, and other intestinal hormones. It inhibits motility of the gallbladder and intestines and suppresses the secretion of lipase by the pancreas.

Serotonin. Serotonin, or 5-hydroxytryptamine, is an amine that is formed from amino acid 5-hydroxytrytophan, in the enterochromaffin cells (EC) and in other similar

cells called enterochromaffin-like cells (ECL). These cells also secrete histamine and kinins, which likewise have important messenger functions in glandular secretions and on blood vessels. Serotonin acts in paracrine fashion. Both EC and ECL cells are widely distributed in the gastrointestinal tract.

Cholecystokinin. A peptide secreted by the I cells in response to the emptying of the stomach contents into the duodenum, cholecystokinin causes contraction of the gallbladder with emptying of its contents, relaxation of the sphincter closing the end of the bile duct, and stimulation of the production of enzymes by the pancreas. Cholecystokinin increases intestinal peristalsis, and it is used in radiological examination of the gallbladder and in tests of pancreatic function.

Uses of cholecystokinin

Gastric inhibitory peptide. Secreted by the K cells, gastric inhibitory peptide enhances insulin production in response to high concentration of blood sugar, and it inhibits the absorption of water and electrolytes in the small intestine. The cell numbers are increased in persons with duodenal ulcer, chronic inflammation of the pancreas, and diabetes resulting from obesity.

Intestinal glucagon. Secreted by the L cells in response to the presence of carbohydrate and triglycerides in the small intestine, intestinal glucagon (enteroglucagon) modulates intestinal motility and has strong trophic influence on mucosal structures.

Motilin. A high level of motilin in the blood stimulates the contraction of the fundus and antrum and decreases gastric emptying. It contracts the gallbladder and increases the squeeze pressure of the lower esophageal sphincter. Motilin is secreted between meals.

Neurotensin. Secreted by the N cells of the ileum in response to fat in the small intestine, neurotensin modulates motility, relaxes the lower esophageal sphincter, and blocks the stimulation of acid and pepsin secretion by the vagus nerve.

Pancreatic polypeptide. Special endocrine cells, "PP" cells, secrete pancreatic polypeptide in response to protein meals. Their function is intimately related to vagal and cholinergic activity. The level of pancreatic polypeptide is frequently raised in diabetes.

Secretin. Secreted by the S cells of the duodenum in response to meals and to the presence of acid in the duodenum, secretin stimulates the production of bicarbonate by the pancreas.

Vasoactive intestinal peptide. Secreted locally by endocrine cells or nerve endings, vasoactive intestinal peptide is located almost exclusively in nerves distributed throughout the gastrointestinal tract. It inhibits the release of gastrin and the secretion of acid and is a mild stimulant of bicarbonate secretion from the pancreas and a powerful stimulant of the secretion of water and electrolytes by the small and large intestines. It relaxes the sphincters and slows intestinal transit time. There is a further group of peptide messengers that is found in quantity within the brain and in the nerves of the gastrointestinal tract. These include substance P, endorphins, enkephalins, and bombesin.

Substance P. Present in significant amounts in the vagus nerves and the myenteric plexus, substance P stimulates saliva production, contraction of smooth muscle cells, and inflammatory responses in tissues, but it is uncertain whether it is other than an evolutionary vestige.

Endorphins and enkephalins. Endorphins and enkephalins, each comprising five amino acids in the molecule, are present in the vagus nerves and the myenteric plexus. They have the properties of opiate (opium-derived) substances such as morphine; they bind to the same receptors and are neutralized by the opiate antagonist naloxone. There is no evidence that endorphins and enkephalins are circulating hormones, but the enkephalins may have a physiological paracrine role in modulating smooth muscle activity in the gastrointestinal tract, and endorphins may serve in modulating the release of other peptides from endocrine cells in the digestive system.

Properties of endorphins and enkephalins

Bombesin. A peptide that is found in the intrinsic nerves of the gastrointestinal tract, bombesin stimulates the release of gastrin and pancreatic enzymes and causes contraction of the gallbladder. These functions may be secondary, however, to the release of cholecystokinin, a hormone secreted by the mucosa of the intestine that has similar effects. It is uncertain if bombesin has a physiological role in humans or if it is an evolutionary vestige.

THE GASTROINTESTINAL TRACT AS AN ORGAN OF IMMUNITY

The body is continuously exposed to damage by viruses, bacteria, and parasites; ingested toxins and chemicals, including drugs and food additives; and foreign protein of plant origin. These insults are received by the skin, the respiratory system, and the digestive system, which constitute the interface between the "perfect" and sterile body interior and the environment.

The defense of the body is vested largely in the lymphatic system and the lymphocytes in it. A substantial part of the gastrointestinal tract is occupied by lymphoid tissue, which can be divided into three sectors. The first is represented by the pharyngeal tonsils, the appendix, and the large conglomerates known as Peyer's patches sited at intervals throughout the small intestine. The second sector includes the lymphocytes and plasma cells that populate the basement membrane (lamina propria), the loose connective tissue area above the supporting tissue of the mucosal lining extending into the villi. The third sector comprises lymphocytes, which lie between the epithelial cells in the mucosa. The basis of defense of the gastrointestinal tract is the interaction between these cells of the lymphatic system and the threatening agent.

Lymphocyte classes

Lymphocytes are of two types, B and T, according to whether they originate in the bone marrow (B) or in the thymus gland in the chest (T). On leaving their tissue of origin, both types end up in the peripheral lymphoid structures. These include the peripheral lymph glands, the spleen, the lymph nodes in the mesentery of the intestine, the Peyer's patches, and the spaces between the epithelial cells of the mucosa.

Lymphocytes are described as immature until they come into contact with antigens. If this foreign material is recognized as such by T cells (T lymphocytes), the cells undergo a process of maturation. They proliferate and divide into subclasses. The first subclass comprises the "helper" T cells, which are mediators of immune function. The second class consists of "suppressor" T cells, which modulate and control immune responses. The third class comprises the "killer" T cells, which are cytotoxic (*i.e.*, they are able to destroy other cells). Most of the lymphocytes lying between the epithelial cells of the mucosa are killer T cells.

When B cells (B lymphocytes) recognize antigen, they also mature, changing to the form known as plasma cells. These cells elaborate a highly specialized protein material, immunoglobulin (Ig), which constitutes antibodies. There are five varieties of immunoglobulin, IgA, IgM, IgG, IgD, and IgE. The cells in the spaces of the basement membrane are mainly B cells and plasma cells. Another group of specialized cells are known as M cells. These are stretched over and around ordinary epithelial cells of the mucosa. The M cells have a function in transportation: they package antigenic material into vesicles and move it through the cell and into the surrounding spaces.

Lymphocytes of the Peyer's patches undergo migration. They pass through lymph vessels to the nodes in the mesentery and then to the thoracic duct. This is the collecting channel in the abdomen, which passes up through the thorax to drain into the venous system at the junction of the left internal jugular and left subclavian veins. The various ramifications of the abdominal lymphatics all drain into the thoracic duct. From there, the lymphocytes are carried back to the intestine as well as being dispersed to other organs. It is these migrated lymphocytes that come to populate the basement membrane and to occupy the spaces between epithelial cells.

Immunoglobulin classes

Most cells in the mesenteric nodes and the basement membrane are plasma cells that produce immunoglobulin of class IgA, while IgM and, to a lesser extent, IgE are produced by other cells, and IgG is formed by cells in the spleen and peripheral lymph nodes. The IgA of plasma cells is secreted into the lumen of the intestine, where it

is known as "secretory IgA" and has a different molecular structure from that of the IgA circulating in the blood. When secreted, it is accompanied by a glycoprotein that is produced by the epithelial cells of the mucosa. This substance, when attached to the IgA molecule, protects it from digestion by protein-splitting enzymes. This IgA complex can adhere to virus and bacteria, interfering with their growth and diminishing their power to invade tissue. It is also capable of rendering toxic substances harmless.

Formed by B cells, IgE coats the surface of mast cells, which are specially adapted to deal with the allergic challenge posed by parasites and worms.

The newborn infant is protected by already-matured immunoglobulin with which the colostrum is richly endowed. Colostrum is the initial secretion of the lactating breast. As time passes, the gastrointestinal tract of the infant is increasingly exposed to various insults, and the lymphocytes and other cells of the immune system become adapted to deal with these. In this way, the body also develops a tolerance to potentially offending substances. If invasion of tissue occurs despite these various defenses, then a generalized systemic immune reaction is marshaled. Some of the features of this reaction, such as fever and a massive increase in the white blood cells, are the evidence of illness. For detailed treatment of the immune system, see IMMUNITY. (W.S.)

Disorders and diseases of the digestive system

IMMUNE-RELATED DISORDERS

Some individuals fail to produce adequate amounts of certain classes of immunoglobulin. Consequently, they suffer from overgrowth of bacteria in the small intestine and from protozoal and other parasitic infections. Because this often leads to massive accumulations of lymphocytes and plasma cells, the lining of the intestine may become studded with nodules that may interfere with the absorptive functions of the small intestine.

IgA deficiency. Immunoglobulin A (IgA) deficiency is a selective disorder that affects about one out of every 500 infants and arises out of a genetically endowed defect. It results in the inadequate production of IgA. These individuals are prone to allergic reactions to a variety of proteins, such as that in cow's milk. They also have a low resistance to infection by fungi.

Genetically endowed defect

There are a number of uncommon conditions that result from defects in the immune system. They are usually evident as chronic diarrhea, malabsorption, or a relative failure of mucosal cell repair and replacement, resulting in a tendency for the intestinal mucosa to atrophy. These include a disorder known as alpha-chain disease, in which the molecular structure of the IgA is faulty and the amino acid sequence in the chain is disturbed. Besides diarrhea and "opportunistic" infections with viruses, bacteria, or fungi (so called because they take advantage of the reduced immune capability of the individual) there is an increased risk of ultimately developing malignant disease.

Failure of this kind in the immune system may have resulted from other diseases of the intestinal tract. For example, a number of diseases can so damage the gastrointestinal lining that protein leaks out and is lost in the feces. This state is designated by the general term protein-losing enteropathy. In this condition, lymphocytes and immunoglobulin are lost as well.

Organ or tissue rejection after transplantation occurs when the graft and host tissues show a disparity in the tissue markers of the sixth chromosome (known as the HLA histocompatability complex). In the gastrointestinal tract this reaction leads to severe destruction and subsequent atrophy of the mucosa, resulting in malabsorption.

Another failure of the immune system is due to a deficiency in the ability of certain white blood cells, the neutrophils (leukocytes), to kill the viruses and bacteria that they ingest. As a result, mucosal destruction, severe diarrhea, and secondary malabsorption occur with chronic inflammation in the mucosa. The condition is known as chronic granulomatous disease of childhood, "granulomatous" because of the large conglomerates of lymphocytes and giant multinuclear cells that develop in the mucosa.

Chronic granulomatous disease

Most of the deficiency states of the body's immune system have a heightened risk of subsequent malignant disease, especially of the lymphomas, which involve the lymphoid tissues.

Crohn's disease. A chronic inflammatory and ulcerative disease of the gastrointestinal tract, named after one of the physicians who first described it, Crohn's disease has many features of abnormal immune reactions. These include the production of antibodies to colonic bacteria and to milk proteins. Various complications affecting the liver, skin, and joints indicate damage due to the deposition of immune complexes, which arise from the interaction between the antigen and the antibody. The combined antigen–antibody complex circulates in the blood, and those that are not promptly removed by the liver or other components of the reticuloendothelial system (a defensive system of the body comprising phagocitizing cells) may be deposited in the linings of the blood vessels and in the skin, the joints, the kidneys, and elsewhere, commencing a disease process.

MOUTH AND ORAL CAVITY

Besides local disease, features characteristic of systemic disorders are often present on the mouth and in the oral cavity. The lips may be fissured and eroded at the corners in riboflavin deficiency (angular chelitis). Multiple brown freckles on the lips associated with polyps in the small intestine is characteristic of Peutz-Jegher's syndrome. Spider nevi, which are prominent in chronic liver disease, are not confined to the face or congregated on the lip margins. Aggregates of small yellow spots on the buccal mucosa and the mucosa behind the lips indicate Fordyce's "disease." The spots are due to the presence of enlarged sebaceous glands just below the mucosal surface.

The most common mouth ulcers are due to aphthous stomatitis. These affect one out of every five Caucasians. The spectrum of this condition ranges from one or two small painful vesicles rupturing to form round or oval ulcers, occurring once or twice a year and lasting seven to 10 days, to deep ulcers of one centimetre or more in diameter. The ulcers are frequently multiple, occur anywhere in the mouth (on the tongue or the palate), and may persist for months at a time. The disability ranges from a mild local irritation to severe distressing pain that prevents talking and eating. Scarring can be seen at the sites of previous ulcers. Aphthous ulceration is sometimes associated with psychological stress, but it may also be a reflection of an underlying malabsorptive disease such as celiac disease. Treatment is directed to the predisposing cause. Local anesthetic agents and analgesics may permit talking and eating. Topical and systemic corticosteroids are the most effective treatment. In a more serious condition, Behçet's syndrome, similar ulcers occur in the mouth and on the genitalia, and the eyes are involved.

Aphthous ulcers

Discoloration of the tongue, commonly white, is due to deposits of epithelial debris, effete (or worn out) bacteria, and food. It occurs in circumstances in which there is reduced saliva production. This may be acute, as in fevers, when the body temperature is high and loss of water through the skin is excessive. The reduced saliva flow in fever is a conservation phenomenon, akin to oliguria (reduced urine losses) and constipation. The discoloration becomes chronic following atrophy of the glands and in the absence of good oral hygiene. If the person is a heavy smoker, the deposit is coloured brown. Black discoloration of the tongue with the formation in the centre of a dense pellicle of fur (black hairy tongue) may be due to a fungus with pigmented filaments. Occasionally it simply represents excessive elongation of the filiform papillae. It may be due to sucking licorice candy.

Tongue discoloration

A bald tongue, with a smooth surface due to complete atrophy of the papillae, is seen in severe iron-deficiency anemia, pernicious anemia, and pellagra, a disorder of skin and mucous membranes due to niacin deficiency. This condition occurs in cereal eaters, usually of corn, when the cereal is contaminated or has a low content of the vitamin that leads to an imbalance in the amino acids derived from food. The condition is endemic in underdeveloped countries in which there are periods of famine.

A deeply fissured tongue (scrotal tongue) may be due to a congenital variation in the supporting tissue of the tongue, but it can be acquired. There is a mild degree of inflammation in the fissures, which causes a slight burning discomfort.

Geographic "tongue," or migrating exfoliative glossitis, describes areas of denudation of the surface of the tongue of various shapes and sizes. These gradually become reepithelialized with regrowth of the filiform papillae, only for the inflammatory process to begin elsewhere in the tongue. Thus, the picture changes with time as the bald zones move around the tongue. These changes usually give rise to no symptoms or, at the most, to a mild burning sensation. The cause is unknown, and the condition may persist for years.

Trench mouth

Vincent's disease (trench mouth) is an ulcerating, necrotizing infection of the gingiva (gums) notable for the spontaneous bleeding from affected areas and the foul odour of the breath arising from the gangrenous tissue. It is endemic in countries where there is severe malnutrition and poor oral hygiene. The infection probably involves several organisms, including spirochetes and fusiform bacilli. It is uncertain if in the developed countries it is transmitted by the exchange of saliva in kissing, but its epidemic increase in wartime and its frequency in the promiscuous suggest this. Vincent's disease responds to antibiotics followed by trimming of the gum margins to eliminate subgingival pockets.

Malignant disease, or cancer, of the mouth is sometimes caused by chronic thermal irritation in heavy smokers and is often preceded by leukoplakia (plaque-like patches arising on the mucous membranes of the cheeks, gum, or tongue). Similarly, cancer of the mouth can be caused by the habit of keeping tobacco or a package of intensely "hot" spices in the space between the cheek and the teeth. These cancers arise from the squamous cells that line the oral mucosa. Cancers of the salivary glands and of the mucous membranes of the cheeks cause pain, bleeding, or difficulty in swallowing. The lymphomas and other tumours of lymphoid origin may first appear in the tonsillar or pharyngeal lymph nodes. Cancer of the tongue and of the bony structures of the hard palate or sinuses may project into the mouth or may burrow deep into the surrounding tissues.

Dental caries. Dental caries are due to the destruction of the dental enamel and underlying tissues by organic acids. These acids are formed by bacteria growing in debris and food accumulated in pockets between the base of the teeth and the gum margins. This periodontal infection ultimately leads to the invasion of the dental pulp, and the involvement of the nerve in the inflammation is the cause of toothache. An abscess may form at the apex of the tooth and extend into the jawbone, causing osteomyelitis (inflammation of the bone), or into the soft tissues around the roots of the teeth, causing cellulitis (inflammation of the soft tissues). Halitosis is due to the rotting debris in the pockets under the gum margins. In due course the teeth loosen and fall out or need to be extracted. Poor oral hygiene is the underlying predisposing circumstance. Malnutrition due to poverty, alcoholism, and malabsorption of vitamin D (rickets) or of proteins (as in celiac disease), initiate or aggravate caries. The resistance of the dental enamel to damage by organic acids is increased by fluoride, and in many countries this is incorporated into the toothpaste formula and is added to the water supplied to homes. In areas where these steps have been taken, the incidence of caries has dropped by more than 50 percent.

Pharyngitis. Inflammation of the posterior wall of the mouth and of the tonsils and adjoining tissue on each side of the oropharynx is very common, especially in young persons. Such infections are due to bacteria of the streptococcal and staphylococcal species, but it should be emphasized that just as many diffuse inflammatory reactions in these tissues result from viral infections as from invasion by pyogenic (pus-forming) bacteria. In viral pharyngitis the tissue is usually less violently red and swollen than is true of streptococcal pharyngitis and it is less often covered by a whitish exudate. Other tonsillar tissue in the upper part of the pharynx and at the root of the tongue may be similarly involved. In diphtheritic pharyngitis, the membranous exudate is more diffuse than in other types of pharyngitis, it is tougher, and it extends over a much larger part of the mucous membrane of the mouth and nose. One of the complications of any tonsillitis or pharyngitis may be a peritonsillar abscess adjacent to one tonsil; this appears as an extremely painful bulging of the mucosa in the area. Surgical evacuation is usually required.

Causes of pharyngeal infections

Inborn defects. The most important of the inborn defects is harelip, which involves failures in fusion of the palate (the bones and soft tissues of the roof of the mouth), thus impairing the ability to produce a closed, high-pressure cavity behind the lips and teeth. Other disorders are related to defective apposition of the teeth and the jaws, resulting in inefficient mastication, and to the absence of one or more of the salivary glands, which may lessen the amount and quality of saliva that they produce. Neurological defects that provide inadequate motor power to the muscles of the tongue and the pharynx can seriously impair mastication and even swallowing. Sensory-innervation defects may not allow the usual reflexes to mesh smoothly, or they may permit harmful ingestants to pass by undetected.

SALIVARY GLANDS

Hyposecretion of saliva

The secretion of saliva is markedly diminished in states of anxiety and anxiety depression. The consequent dry mouth interferes with speech, which becomes thick and indistinct. In the absence of the cleansing action of the saliva, food debris persists in the mouth and stagnates, especially around the base of the teeth. The debris is colonized by bacteria and causes foul breath (halitosis). In the absence of saliva, swallowing is impeded by the lack of lubrication for the mastication of food that is necessary to form a bolus. The condition is aggravated in states of anxiety depression when drugs that have an anticholinergic-like activity (such as amitriptyline) are prescribed, because they further depress the production of saliva. The salivary glands are severely damaged and atrophy in a number of autoimmune disorders such as Sjögren's disease and systemic lupus erythematosus. The damage is done partly by the formation of immune complexes (antigen–antibody associations), which are precipitated in the gland and initiate the destruction. In these circumstances, the loss of saliva is permanent. Some symptomatic relief is obtained by the use of "artificial saliva," methylcellulose mouthwashes containing herbal oils such as peppermint. As some of the salivary glands retain their function, they may be stimulated by chewing gum and by a parasympathomimetic agent such as bethanecol. The production of saliva may be impaired by infiltration of the salivary glands by pathological lymphocytes, such as in leukemias and lymphomas. In the early stages of these diseases, the glands swell and become painful.

Excessive production of saliva may be apparent in conditions interfering with swallowing, as in parkinsonism due to disease of the brain stem and basal ganglia of the brain, or in pseudobulbar paralysis from blockage of small arteries to the midbrain regions. Both conditions bring about drooling. True salivary hypersecretion is seen in poisoning due to lead or mercury used in certain industrial processes, and as a secondary response to painful conditions in the mouth, such as aphthous stomatitis (certain ulcers of the oral mucosa) and advanced dental caries.

Acute and painful swelling of a salivary gland develops when salivary secretion is stimulated by the sight, smell, and taste of food but a salivary duct is obstructed. The swelling and pain that develop because saliva is prohibited from flowing through the duct subside between meals. The diagnosis can be confirmed by X ray. Persistent swellings may be due to infiltration by benign or malignant tumours or to infiltration by the abnormal white blood cells, as in leukemia. The most common cause of acute salivary swelling is mumps.

ESOPHAGUS

Dysphagia

Difficulty in swallowing (dysphagia) may be the only symptom of a disorder of the esophagus. Sometimes difficulty in swallowing is accompanied by pain (odynophagia), or

pain may occur spontaneously without swallowing being involved. The esophagus does nothing to alter the physical or chemical composition of the material it receives, and it is poorly equipped to reject materials that have gotten past the intricate sensors of the mouth and throat. Consequently, it is peculiarly vulnerable to mucosal injury from ingestants, as well as to materials that reflux into its lower segment from the stomach. Although its muscle coats are thick, it is not protected with a covering of serous membrane, as are neighbouring organs in the chest.

Congenital disorders. Inborn defects of the esophagus are most often seen in infancy, primarily as a failure to develop normal passageways. An opening often occurs between the esophagus and the trachea. Babies born with these openings cannot survive without early surgery. The lower end of the esophagus is subject to various developmental anomalies that shorten the organ so that the stomach is pulled up into the thoracic cavity. Anomalies of the diaphragm may contribute to a similiar outcome.

Inflammatory disorders of the esophagus result from a variety of causes; for example, ingestion of noxious materials as in lye or acid burns, lodgment of foreign bodies, or a complex of events associated with reflux of gastric contents from the stomach into the lower esophagus. All types of trauma produce damage to the mucous membrane of the esophagus. Inflammation resulting from surface injury by caustics is called corrosive esophagitis. When the problem is associated with reflux, the term peptic esophagitis is applied to inflammation, which involves both the mucous membrane and the submucosal layer in a generally mild process. A number of other diseases may cause inflammation of the esophagus; *e.g.*, scleroderma, a disease in which the smooth muscle of the organ degenerates and is eventually replaced by fibrous tissue; and generalized moniliasis, in which the esophagus is often involved in a septic process characterized by many small abscesses and ulcerations throughout its entire length.

Peptic esophagitis

Strictures. It is characteristic of all fibrous (scar) tissue that it contracts over time. Consequently, when fibrous tissue is laid down around a tube, as in the esophagus, in response to inflammation, the contracting scar narrows the lumen, causing a stricture, and may come to obstruct it totally. Strictures are readily diagnosed by X ray and by viewing directly through an esophagoscope.

Dysphagia. Most individuals can locate the site of the dysphagia (difficulty in swallowing) and the distribution of the pain with accuracy. A sense of food sticking or of pain on swallowing, however, may be felt to be in the throat or upper sternum when the obstruction or disease is in fact at the lower end of the esophagus. The sensation of a "lump in the throat" that is not connected with eating or swallowing is called "globus hystericus." This is an expression of a psychoneurosis and is accompanied by other symptoms indicative of this. Globus hystericus is managed by explanation and treatment of the underlying nervous disorder.

The neural arc of swallowing involves the medulla of the brain stem, the vagus (10th cranial) nerves, and the glossopharyngeal, trigeminal, and facial nerves. Consequently, dysphagia may result from interference with the function of any part of this pathway. Thus, it occurs commonly, but usually transiently, in strokes. Dysphagia may be prominent in degenerative disease of the central nervous system, especially of the ganglia at the base of the brain. In these circumstances, it is the behaviour of the smooth muscle of the pharynx and the upper esophageal sphincter that is disturbed.

Pain. The nerve fibres conveying the sense of pain from the esophagus pass through the sympathetic system in the same spinal cord segments as those that convey pain sensations from the muscle and tissue coverings of the heart. Episodes of pain arising from the esophagus as a result of muscle spasm or transient obstruction by a medicine tablet or other object may be experienced in the chest and posterior thorax and radiate to the arms. It thus mimics angina (pain) of cardiac origin (pseudoangina). The pain due to transient obstruction may be felt not only in the chest but also, through radiation to the back, between the shoulder blades. Because this is very similar to pain from gallstones, attacks lasting 10 to 30 minutes mimic that condition.

Pseudoangina

In middle-aged and elderly persons, spontaneous and diffuse spasm of the smooth muscle of the esophagus causes considerable discomfort as well as episodes of dysphagia. Alternative names for the condition are "corkscrew" esophagus and diffuse spasm of the esophagus. The appearance of the esophagus seen on an X-ray screen while a barium bolus is swallowed resembles that of the outline of a corkscrew because of the multiple synchronous contractions at different levels of the spirally arranged smooth muscle.

Drugs that relieve cardiac angina may also relieve the pain of esophageal spasm, especially nifedipine. In persons over 50 years of age, the sensation of food "sticking" is more often caused by a disease process, frequently a tumour, involving the wall of the esophagus and providing a mechanical rather than a functional obstacle to the passage of food.

Motility. Disorders of the motility of the esophagus tend to be either precipitated or aggravated at times of nervous stress. Eating rapidly is another trigger, as this demands more precise and rapid changes in muscle activity than eating slowly. An interesting disease of the esophagus is achalasia, formerly called cardiospasm. In this disorder, a primary disturbance in the peristaltic action of the esophagus results in failure to empty the organ of its ingested and swallowed contents. The lower sphincteric portion of the esophagus does not receive its customary signal to relax and, over the months and years, may become hypertonic, resisting stretching. A vicious cycle is thus set up in which the main portion of the esophagus slowly becomes distended, holding a column of fluid and food that it cannot propel downward to a lower exit valve mechanism that stays closed because of a failure in its information-feedback system. In most persons with this disorder, there is a shortage or disease of ganglion cells of the intramuscular plexus (Auerbach's plexus), or a disease of the network of nerves within the muscles of the esophagus, so that coordinated peristalsis becomes impossible. In Chagas' disease, the infecting trypanosomes invade the neural tissue and directly destroy the ganglion cells. These organisms are not present in the temperate zones of the world, however, and the reason for ganglion cell degeneration in achalasia is generally unknown. Effective treatment is achieved by destroying the ability of the lower esophageal sphincter of the esophagus to contract. This may be done by forcible dilatation, using a balloon, of the esophagus in the area that is tonically contracted. The objective is to rupture the circular muscle at that site, and this is generally achieved with one or two dilatations. If this fails to overcome the contraction or if the contraction recurs, the surgical cure involves opening the abdomen and cutting through the circular muscles from the outside of the esophagus. The disadvantage of both methods of treatment is that the antireflux mechanism is thereby destroyed. Consequently, if precautions are not taken, the individual may lose the symptoms and risks of achalasia but may develop the symptoms and signs of reflux peptic esophagitis.

Onset of disorders of motility

Gastroesophageal reflux. In healthy individuals, reflux of gastric contents into the esophagus occurs occasionally. This causes the burning sensation behind the sternum that is known as heartburn. It may be accompanied by regurgitation, some of the refluxed material reaching the pharynx where it also may be felt as a burning sensation. Reflux is most likely to occur after large meals, especially if physical activity, including bending, stooping, or lifting, is involved. In these circumstances, the esophagus responds with peristaltic waves that sweep the gastric contents back into the stomach, with rapid relief of the heartburn.

Persistent reflux symptoms are invariably due to inadequate functioning of the anatomical components, such as the lower esophageal sphincter, which keep the contents of the stomach below the diaphragm. The disorder is most commonly due to obesity. Excessive fat on the trunk is almost always accompanied by large deposits of fat within the abdomen, especially in the mesentery (the curtain-like structure on which most of the intestine is hung). Consequently, when intra-abdominal pressure is increased, such

Mechanism of reflux

as in physical activity, there is insufficient room within the abdomen to accommodate the displacement of the organs, and the resulting pressure forces the stomach upward. The weak point is the centre of the diaphragm at the opening (hiatus) through which the esophagus passes to join the stomach. The upper pole of the stomach is pushed through the hiatus, and the distortion of the anatomical relations brings about impaired functioning of the anti-reflux mechanisms. In the early stages the stomach may slide back into the abdomen when the increase in the intra-abdominal pressure eases, but eventually, if the circumstances are unchanged, the upper part remains above the diaphragm. A common contributory cause in women is pregnancy. As the uterus containing the developing fetus comes to occupy a large part of the abdomen, the effect is the same as in obesity. Because only gravity keeps the gastric contents within that organ, once a hernia is established, the reflux and the symptoms from it promptly occur when the individual lies down. Persisting reflux of gastric contents with acid and digesting enzymes leads to chemical inflammation of the lining of the esophagus and ultimately to (peptic) ulceration. If inadequately treated, the process leads to submucosal fibrosis and stricturing, and, besides the symptoms of heartburn and regurgitation, the patient experiences pain on eating and swallowing.

Treatment of reflux

The treatment of peptic esophagitis includes eliminating obesity, avoiding activity that increases intra-abdominal pressure, and raising the head of the bed high enough to discourage nocturnal gastroesophageal reflux. Mixtures of alkali and alginic acid derivatives that are viscous and adhere to the inflamed area of mucosa are effective and are aided by taking agents that reduce the secretion of acid by the stomach, such as those blocking the receptors on the surface of the parietal cells. If a stricture has formed, it can be dilated easily. If the disability is not overcome with these conservative measures, surgical repair is undertaken through either the chest or the abdomen. When feasible, the vagus nerves may be cut to stop acid secretion permanently.

In some individuals with severe reflux esophagitis, the repair of the damaged lining of the esophagus after conservative treatment is brought about by relining the esophagus with columnar cells. These cells are similar to those lining the upper part of the stomach and are not the usual squamous cells that line the esophageal mucosa. In some persons in whom this transformation occurs, a carcinoma develops some 10 to 20 years later. The decision as to the treatment of a hiatus hernia by conservative means or by surgery is influenced by such factors as the age of the patient, his occupation, and the likelihood of compliance with a strict regimen.

There is a much less common form of hiatus hernia, called paraesophageal, in which the greater curvature of the stomach is pushed up into the thorax while the esophagogastric junction remains intact below the diaphragm. Such individuals experience dysphagia caused by compression of the lower esophagus by the part of the stomach that has rolled up against it. This rarer form of hernia is more dangerous, often being complicated by hemorrhage or ulceration, and requires relief by surgery.

Diverticula. Pouches in the walls of the structures in the digestive system that occur wherever weak spots exist between adjacent muscle layers are called diverticula. In the upper esophagus, these may occur in the area where the striated constrictor muscles of the pharynx merge with the smooth muscle of the esophagus just below the larynx. Some males over 50 years of age show protrusion of a small sac of pharyngeal mucous membrane through the space between these muscles. As aging continues, or if there is motor disturbance in the area, this sac may become distended and actually fill with food or saliva. It usually projects to the left of the midline, and its presence may become known by the bubbling and crunching sounds produced during eating. Often the patient can feel it in the left side of the neck as a lump, which can be reduced by pressure of the finger. Sometimes the sac may get so large that it compresses the esophagus adjacent to it, producing a true obstruction. The treatment is by surgery. Small diverticula just above the diaphragm sometimes are found after the introduction of surgical instruments into the esophagus.

Pharyngeal diverticulum

A serious injury to the esophagus is spontaneous rupture. It can occur in patients who have been vomiting or retching and in debilitated elderly persons with chronic lung disease. Emergency surgical repair of the perforation is required. A rupture of this type confined to the mucosa only at the junction of the linings of the esophagus and stomach is called a Mallory-Weiss lesion. At this site, the mucosa is firmly tethered to the underlying structures and, when repeated retching occurs, this part of the lining is unable to slide and suffers a tear. This leads to immediate pain beneath the lower end of the sternum and bleeding that is often severe enough to require transfusion. The circumstances preceding the event are commonly the imbibing of a large quantity of beer or other alcoholic drink followed by eating and then vomiting. The largest group of individuals affected are alcoholic men. Diagnosis is made by direct vision using an endoscope. Most ruptures spontaneously stop bleeding, and the tear heals over the course of some days. If transfusion does not correct blood loss, surgical suture of the tear may be necessary. An alternative to surgery is the use of the drug vasopressin, which shuts down the blood vessels that supply the mucosa in the region of the tear.

Mallory-Weiss lesion

Cancer. Tumours of the esophagus may be benign or malignant. Generally, benign tumours originate in the submucosal tissues and principally are leiomyomas (tumours composed of smooth muscle tissue) or lipomas (tumours composed of adipose, or fat, tissues). Malignant tumours are either epidermal cancers, made up of unorganized aggregates of cells, or adenocarcinomas, in which there are gland-like formations. Cancers arising from squamous tissues are found at all levels of the organ, whereas adenocarcinomas are more common at the lower end where a number of glands of gastric origin are normally present. Tumours produce difficulty in swallowing, particularly of solid foods; they are much more common in men than in women, and they seem to vary greatly in their worldwide distribution. In North China, for example, the incidence of esophageal cancer in men is 30 times that of white men in the United States and eight times that in black men. The incidence in Europeans is much the same as in the United States, except in France, where it is higher. Some correlations with the alcohol or tobacco consumption of the population have been established, suggesting that continued ingestion or inhalation of these materials may predispose a person to malignant change. In the United Kingdom, for example, there is a higher than average incidence in men working in the alcohol trade. Previous stricture formation also apparently plays a role.

In women, cancer of the upper esophagus is more common than in men, and women may be predisposed by long-standing iron deficiency, or Plummer-Vinson (Paterson-Kelly) syndrome. Dysphagia is the first and most prominent symptom. Later swallowing becomes painful as surrounding structures are involved. Hoarseness indicates that the nerve to the larynx is affected. The diagnosis is suggested by X ray and proved by endoscopy with multiple biopsies from the area of abnormality. Diagnosis can be reinforced by removing quantities of cells with a nylon brush for examination under a microscope (exfoliative cytology). The prognosis is poor because the tumour has usually been growing for one or two years before symptoms are apparent. The channel of the esophagus is encroached upon and can be almost entirely obliterated. The disease is usually accompanied by considerable weight loss, but nutrition may be restored by dilating the lumen through the tumour and passing a flanged tube prosthesis through it so that the proximal end is above the tumour and the distal end is in the stomach. In advanced cases, this may be the only useful measure. Where the channel is greatly narrowed, the tumour can be debulked by destroying the tissue with lasers. Radiotherapy is used for malignancies of the upper esophagus and as treatment for those at the lower end. Some clinics practice a combination of radiotherapy followed by surgical excision. The five-year survival rate remains very low, 15 percent at best. Lessening the effects of the disease, with restoration of eating

Plummer-Vinson syndrome

ability, is very important, because otherwise the inability to swallow even saliva is distressing and the patient dies slowly from starvation.

The poor results of treating cancer of the esophagus have stimulated the development of new techniques based on endoscope-guided laser light beams. The developments include preliminary uptake of a photosensitizing agent by the tumour before its exposure to laser light and the use of a krypton-fluoride laser with ultraviolet wavelength and a power density of 10^8 watts per square centimetre. The extent and depth of the tumour in the wall of the esophagus can be determined using ultrasound probes under endoscopic guidance.

STOMACH

Indigestion. The stomach moves in a rolling and wringing pattern, beginning about one-third of the way down the length of the organ, propelling the mixture of food and juices toward its outlet, the pylorus. Any disorder that affects the power of coordination of the stomach muscles is capable of producing symptoms ranging from those that are mildly unpleasant to others that are life-threatening. The unpleasant sensations, called anorexia and nausea, seem to be mediated through the central nervous system, with reflex input from nerve endings in the stomach and duodenum. Sometimes the entire duration of a nausea-vomiting episode is so short that it appears to be vomiting alone, obscuring the presence of nausea. This is characteristically noted in persons with primary diseases of the brain, especially those with tumours or meningitis in which the cerebrospinal fluid is under increased pressure. In many diseases, vomiting may not be preceded by nausea at all, and in others there may be a long time lag between nausea and vomiting. Seasickness is the best known example of this relationship.

The intrinsic muscles of the stomach are innervated by branches of the vagus nerves, which travel along the esophagus from their point of emergence in the brain stem. Severing these nerves, as is often done in the surgical treatment of peptic ulcer, may produce temporary or more prolonged change in the ability of the stomach to empty itself. Many drugs, particularly the anticholinergic medications, are often used in the treatment of peptic ulcer. These drugs exert an action comparable to that produced by cutting the vagus nerves, but they have the potential disadvantage of reducing the flow of saliva, interfering with vision by disturbing accommodation reflexes in the pupil, and reducing the power of the muscle on which bladder emptying depends.

Treatment of peptic ulcer

Gastric retention may result from the degeneration of the nerves to the stomach that can result from diabetes mellitus. Obstruction due to scarring in the area of the gastric outlet, or to tumours encroaching on the lumen, causes the stomach to fill up with its own secretions as well as with partially digested food. In these circumstances, vomiting leads to dehydration and to electrolyte losses, which threaten life if not corrected. The ingestion of soluble alkali in this situation may aggravate the disturbance in the acid–base balance of the body. Bulimia, a nervous disorder characterized by compulsive eating followed by vomiting and purging, can cause severe dehydration and even a ruptured stomach, and it can prove fatal.

Ulcerative diseases. The area of the stomach in which acid and pepsin are secreted has the highest resistance to peptic ulcer. The mucosa elsewhere is less well protected, and its breakdown may lead to ulceration. If the breach is confined to the superficial layers of the mucosa, it is called an erosion; if it extends through the intrinsic layer of muscle of the mucosa into the tissues below, it is known as an ulcer. Erosions and ulcers can be acute or chronic according to how readily they heal. The circumstances that contribute to mucosal injury and ulcer formation include physical and chemical trauma that result from hot fluids and food, aspirin and other drugs, irritating spices, and pickling fluids.

Reduction of the secretion of mucus by the stomach and duodenum, or a reduction of bicarbonate secretion (which neutralizes excess acid), lowers resistance. Extracellular paracrine messenger substances, in particular the prostaglandins, which stimulate secretion of mucus and bicarbonate and also stimulate cell replication, may be deficient in the mucosa of individuals with peptic ulcer. The rate of cell replication is lowered by malnutrition.

In the United States and the Western world generally, duodenal ulcer is much more common than gastric ulcer, occurs more often in men than in women, and is aggravated by nervous tension and fatigue. In Japan, gastric ulcer is more common than duodenal ulcer and is thought to be related to the raw fish and acetic acid pickles of the traditional diet.

Disturbed physiology

In 60 percent of persons with duodenal ulcer, acid and pepsin secretion is on the high end of normal, and in 40 percent, it is above normal. Of particular concern in duodenal ulcer is the inappropriate secretion of acid and pepsin due to failure of homeostatic-controlling mechanisms, so that it continues when the stomach is empty and during the night hours. In special circumstances such as the state of shock produced by large burns, intracranial surgery, coronary occlusion, and septicemia, acute and rapidly penetrating ulcers may occur.

Genetic factors are involved in the development of ulcers. Inheriting blood group O and an inability to secrete antigen substance H into body fluids, while secreting the Lewis antigen, renders a person four times more likely to develop duodenal ulceration than average. There are families in whom the secretion of pepsinogen I is excessive and renders them prone to duodenal ulcer since excess acid secretion is linked to excess pepsinogen I secretion. Possession of blood group A increases the chance of developing a gastric ulcer. Otherwise, the secretion of acid and pepsin in individuals with gastric ulcer is normal in all respects. There are other distinct differences between ulcers at the two main sites: duodenal ulcer is most common between 25 and 35 years of age, while gastric ulcer is uncommon before 40 years and has a peak frequency between 55 and 65 years.

Pain is the major symptom of duodenal ulcers. The pain is a burning or gnawing sensation felt in the upper abdomen in the midline below the sternum. In gastric ulcer it comes on soon after eating, whereas in duodenal ulcer it comes on when the stomach is empty, one and a half to two hours after meals and during the night hours. In the early stages of the disease, the pain is easily and immediately relieved by alkalis and, in duodenal ulcer, by light food.

Peptic ulcers naturally show remissions and relapse. Attacks last from four to eight weeks before spontaneously ceasing. In most instances this behaviour corresponds to healing and breakdown of the ulcer, but an active ulcer may produce no symptoms. Gastric ulcers are slower than are duodenal ulcers to pass into remission and to respond to treatment. The fluctuating course of activity continues for five to 20 years or more. At some point in this span, the symptoms disappear in 60 percent of the individuals, never to recur. Of the remainder, 20 percent have surgery at some time because of complications and resistance to cure, and 20 percent have some degree of disability throughout their lives.

Response to treatment

Gastric ulcers almost always recur in the same site within the stomach, but duodenal ulcers are often multiple and recurrence may be anywhere in the bulb. Furthermore, duodenal ulcers are usually accompanied by an inflammation affecting the whole of the bulb (duodenitis). Multiple erosions varying in size between 0.5 and five millimetres are frequently scattered over the mucosa. With gastric ulcers the inflammation is usually confined to the immediate vicinity of the crater and, as a rule, is not accompanied by erosions. The exceptions are gastric ulcers in the antrum and prepyloric area associated with the use and abuse of analgesics and nonsteroidal anti-inflammatory drugs for arthritic disorders, in which multiple erosions are commonly present.

The most common site of gastric ulcers is halfway up the inner curvature of the stomach at the junction of the lower one-third with the upper two-thirds. This may be because blood flow to this site is more easily reduced than elsewhere. Chronic gastric ulcers at this site are strongly associated with obstructive disease of the airways (chronic

bronchitis and emphysema). Smoking impairs the healing of both gastric and duodenal ulcers.

Complications

The complications of peptic ulcers are hemorrhage, perforation, and obstruction of the outlet of the stomach (pyloric stenosis) by scarring of the duodenal bulb or of the pyloric channel. Bleeding may be obscured because of oozing from the floor of the ulcer and detectable only by testing the feces with blood-sensitive agents, or bleeding may be brisk, leading to the passage of tar-coloured stools (melena). Occasionally when the ulcer erodes into a large vessel bleeding is torrential and life-threatening. Brisk bleeding is usually accompanied by the vomiting of blood (hematemesis), which requires treatment by blood transfusion. In the elderly, hardening of the arteries (arteriosclerosis) prevents the vessel from closing down around the breach. If bleeding persists or recurs, surgery becomes necessary. Ulcers that penetrate the back wall of the stomach or duodenum erode into the pancreas, and back pain becomes prominent. If the ulcer penetrates the anterior wall, free perforation into the abdominal cavity may occur. This causes immediate, intense pain and shock, and the abdominal wall becomes rigid. In most instances this requires emergency surgery with drainage of the abdomen.

Obstruction of the gastric outlet through the pylorus and duodenum by scarring leads to bouts of vomiting and accompanying malnutrition and requires surgery. The mortality of bleeding is high in the aged because of chronic changes in the lungs, heart, and blood vessels, which reduces cardiorespiratory reserves. This is further aggravated by smoking.

Surgery for chronic ulceration is used less frequently since the introduction of powerful drugs that block the pathways of stimulation of the parietal cells and of others that increase the resistance of the mucosa. Two major classes of drugs are involved. The first class comprises drugs such as cimetidine and ranitidine, H_2-receptor antagonists that engage the histamine receptor sites on the outer membrane of the parietal cells without initiating the production of acid. These drugs are called antagonists because they bind a receptor but do not elicit its normal response. The second class of drugs has no effect on acid secretion but lowers the activity of pepsin by absorption, binds to the tissue in the floor of an ulcer and forms a clot and increases the resistance of the mucosa to break down. This class includes sucralfate and tripotassium dicitrato-bismuthate. A third class, which inhibits the ATPase enzyme inside the cell, preventing the pumping out of the acid ions, is being studied. The most promising agents for treating peptic ulcer diseases are the prostaglandins because they inhibit acid secretion and protect the tissue.

For most individuals, a single tablet of an H_2-receptor antagonist taken before sleeping is adequate to control the disease and can be used for long-term suppression. A proportion of persons taking this drug relapse and need a higher dosage from time to time.

Gastritis. A diffuse inflammation of the stomach lining, gastritis is usually an acute process caused by contaminated food, alcohol abuse, or by bacterial- or viral-induced inflammation of the gastrointestinal tract (gastroenteritis). Such episodes are short-lived and require no specific treatment. Unlike the pain of ulcerative disease, the discomfort is generalized in the upper abdomen and is continuous, but it progressively subsides over two or three days. Aspirin and nonsteroidal anti-inflammatory drugs taken for arthritis cause erosions in the antrum of the stomach, which in some instances becomes chronic ulceration. This usually responds to the withdrawal of the offending drugs and treatment with the same agents used to treat peptic ulcers of the stomach and duodenum. Erosions from drugs are a common cause of bleeding.

Drug erosions

The other form of gastritis is gastric atrophy, in which the thickness of the mucosa is diminished. This may be the culmination of damage to the stomach over many years. Although the mechanism is not understood, there are immunological features. Diffuse gastric atrophy leads to partial loss of the glands and secreting cells throughout the stomach and may be associated with iron-deficiency anemia. Atrophy of the mucosa confined to the body and fundic regions of the stomach is seen in pernicious anemia and is due to the formation of antibodies to intrinsic factor secreted by the parietal cells. Intrinsic factor is necessary to the absorption of vitamin B_{12}.

Cancer. Malignant tumours of the stomach are common, but they show variations in incidence from country to country, probably a result of both genetic and environmental factors. Cancer of the stomach often occurs in older persons whose stomachs produce only small quantities of acid. Whether this indicates that the same process that depresses acid secretion also causes cancer or that gastric cancer is inhibited normally by the secretion of acid and pepsin is not known. Gastric cancer affects men more often than women and accounts for about 20 percent of all deaths from cancers of the gastrointestinal tract in the United States. In Japan, on the other hand, it accounts for nearly 70 percent of such cancers.

Other malignant tumours that involve the stomach are tumours ordinarily made up of lymphoid and connective tissue, respectively. Benign tumours, especially leiomyomas, are common and may, when large, cause massive hemorrhage. Polyps of the stomach are not common except in the presence of gastric atrophy. Treatment for these tumours, benign or malignant, is surgery.

Symptoms of stomach cancer

Because symptoms produced by tumours of the stomach are highly variable, there are no common characteristics of the disease in its early stages. The symptoms most often seen are loss of appetite, some weight loss, and symptoms attributable to an anemia, a condition that frequently is present because of blood loss into the stools, which, though constant, is usually so minimal as to escape notice by the patient. Tumours in the lower part of the stomach produce obstructive symptoms, and tumours high in the stomach may obstruct the esophageal entry into the stomach, producing difficulty in swallowing. Although pain is usually mild, it may be the most noticeable symptom. Stomach cancers often spread to neighbouring lymph nodes or to the liver in the early stages, accounting for the low percentage of cures by surgery.

DUODENUM

The duodenum, aside from being the site of duodenal peptic ulceration, is otherwise not an important seat of disease. It is, however, often involved in the diseases of its neighbours, in particular the pancreas and the biliary tract. Primary cancer of the duodenum is an infrequent disease. Benign tumours, particularly polyps and carcinoids, are more frequent. Cancers of the common bile duct or of the pancreas are important causes of death and may make their presence known by what they do to the duodenum, particularly in terms of obstruction and pain. It is because of their encroachment on the duodenum that these entities often are diagnosed by upper intestinal X-ray studies. Benign anomalies of the organs of this area, like an encircling ring of pancreas, may also encroach upon the duodenum. In countries of the Middle and Far East, where parasites are endemic, roundworms and tapeworms in particular are often found anchored in the duodenum. In inflammations of the pancreas, the neighbouring duodenum is often involved in such a way as to produce impairment of motility and occasionally ulceration with hemorrhage. A protozoal parasite, *Giardia lamblia,* can contaminate drinking water and is a common cause of diarrhea and, if unrecognized, malabsorption.

SMALL INTESTINE

Causes of cramping pain

A lack of coordination of the inner circular and outer longitudinal muscular layers of the intestinal wall usually results in an accumulation of excess contents in the lumen, with consequent distension. This distension may cause pain and usually results in hyperactive contractions of the normal segment next to the distended area. Such contractions may be strenuous enough to produce severe, cramping pain. The most common cause of disturbed motility in the small intestine is food that contains an unsuitable additive, organism, or component.

Traveler's diarrhea. Traveler's diarrhea is watery, accompanied by cramps, and lasts a few days. It is almost always caused by toxin-generating *Escherichia coli,* less often by other organisms. *Shigella* infection may occur

simultaneously, however, and visitors to countries where giardiasis is endemic may suffer infection. Salads remain the most common cause of traveler's diarrhea in countries where the climate is hot. Such diarrhea generally disappears spontaneously with abstention from food accompanied by drinking of nonalcoholic fluids. Mixtures of sodium and potassium chloride, sodium bicarbonate, and glucose reconstituted with water are one method of treatment.

Intestinal obstruction. The most serious problems in small intestine motor disturbances arise from an intestinal obstruction that results from an actual encroachment on the bowel by an adhesive band or from an internal block produced by a tumour or gallstone. As profound an obstruction results when a portion of the intestine undergoes partial necrosis, or death, from failure of its blood supply. This necrotic section cannot pass peristaltic activity and, for all practical purposes, serves as an obstruction. The death of the tissue, furthermore, results in the escape of highly toxic fluids from the intestinal contents through the wall, producing peritonitis. Surgery is usually necessary early in the course of the illness.

Tissue necrosis

The speed with which the contents are passed along the small intestine is increased by many factors, including swallowing air, the nature or physical characteristics of foods (*i.e.*, whether they are cold or highly spiced), and, most importantly, by emotions. An upright position during physical activity causes the small intestine to swing about on its mesenteric root, so that merely assuming the horizontal position often markedly slows intestinal motor activity.

Irritable bowel syndrome. The extremely common disorder known as the irritable bowel syndrome is probably due to a disturbance of the motility of the whole intestinal tract. The symptoms vary from watery diarrhea to constipation and the passage of stools with difficulty. When the colon is involved, an excess of mucus is often observed in the stools. Pain is most often felt in the lower abdomen and in the left lower quadrant. Generalized abdominal discomfort, sometimes with nausea, may follow defecation and may last 15 to 30 minutes. Most sufferers are nervous persons, and some have periods of anxiety depression. Motor activity in those individuals with diarrhea tends to be decreased in the lower colon, whereas motor activity in those with constipation is increased. The strength of contractions is greatly augmented, the frequency increased, and there are periods of diffuse spasm when a long sector of the colon stays contracted.

Occasionally the irritable bowel syndrome may be due to an allergy to a particular foodstuff. The syndrome may develop following an infection such as bacillary dysentery, after which the small intestine remains irritable for many months. Treatment of the irritable bowel syndrome is best limited to an explanation to the patient, elimination of stress, psychological support, change in life-style if appropriate, and outdoor activities. Possible aggravating items such as lactose-containing foods, coffee, and deep-fried dishes should be eliminated from the diet, and dietary fibre should be added to help in modulating motility and resolving the diarrhea and the costive activity of the condition. When discomfort is prominent, antispasmodic agents that relax smooth muscle, such as dicyclomine hydrochloride or mebeverine, may be prescribed. If diarrhea does not respond to an increase in dietary fibre, diphenoxylate or loperamide may slow the movement of the intestinal contents, thereby increasing the potential for the reabsorption of water.

Malabsorption. Of the mixture of fats, proteins, carbohydrates, minerals, and vitamins that are ingested, it appears that fat is most subject to malabsorption. Measurements of fat absorption have been used for some time as an index of general intestinal malabsorption. Fat must be solubilized to be absorbed, and this requires optimum conditions for the action of bile salts, phospholipids, and lipase. Malabsorption occurs when the small intestine is unable to transport properly broken down products of digestive materials from the lumen of the intestine into the lymphatics or mesenteric veins, where they are distributed to the rest of the body. Defects in transport occur either because the absorptive cells of the intestine lack certain enzymes, whether by birth defect or by acquired disease, or because they are hindered in their work by other disease processes that infiltrate the tissues, disturb motility, permit bacteria to overpopulate the bowel, or block the pathways over which transport normally proceeds.

The basis of malabsorption

Diagnosis of malabsorption is made primarily from the patient's history, physical examination, X-ray films of the abdomen, and study of the stools under controlled dietary conditions. Some test substances can be administered and their recovery measured in the stools and in the blood. Motor aspects of the intestine can be studied using a variety of techniques.

Congenital malformations. Meckel's diverticulum is a common congenital malformation that occurs when the duct leading from the navel to the small intestine in the fetus fails to atrophy and close. The duct serves the fetus as the principal channel for nourishment from the mother. The diverticulum in the child or adult may range from a small opening to a tube that is a foot or more in length and it may contain cells derived from the stomach glands that secrete acid and pepsin. If such secretions spill onto normal intestinal mucosa, which is totally nonresistant to it, the mucosa ulcerates and often bleeds. Thus a peptic ulcer can develop at a site far distant from the stomach or duodenum. The peptic ulcer gives rise to pain, bleeding, or obstruction, and it is the most common cause of bleeding from the lower intestine in children. Meckel's diverticulum must be treated surgically.

Meckel's diverticulum

Another congenital problem in the small intestine is the presence of multiple diverticula, or outpouchings of mucosa and serosa. These are seen usually in elderly persons, although occasionally one may be the site of acute inflammation in a young adult. Bacteria flourish in these diverticula because the outpouchings have no motor activity and cannot empty themselves. The bacteria deprive the body of nutrients and may cause diarrhea and serious malabsorption. The overgrowth of bacteria also upsets the motor activity of the small intestine. Antibiotics may control the condition in the elderly, but surgical resection of diverticula is used in younger persons.

A third congenital malformation is a failure of complete rotation of the small and large intestine, which is a normal step in the development of the fetus. This can result in abnormal intestinal attachments with a subsequent risk of obstruction when the intestine twists around the attachments.

Bacterial infections. Besides the *Shigella* infections described above, other organisms can infest the human body and cause disease. Species of *Salmonella* that cause typhoid and paratyphoid remain endemic scourges in the hot countries and, together with *Shigella*, are occasional causes of epidemics in institutions, especially where the elderly are concerned. The diagnosis is confirmed by the presence of the organisms after a stool culture. Antibiotics and solutions rich in electrolytes are effective therapy. Only severe cases of *Shigella* infection require antibiotics, but typhoid and paratyphoid require hospitalization and, if severe, treatment with chloramphenicol, sulfonamides, or antibiotics. Periodic injection of vaccine is advisable for the protection of individuals exposed to areas where typhoid and paratyphoid are endemic.

Cholera, caused by *Vibrio cholerae*, is endemic to Southeast Asia and periodically becomes pandemic (widely distributed in more than one country). The oral or intravenous administration of electrolyte solutions rich in potassium has revolutionized the treatment of cholera, because deaths are due to a massive depletion of electrolytes and water. The toxin produced by *V. cholerae* attaches to the intestinal cells, the enterocytes, where it stimulates the membrane enzyme adenylate cyclase; this in turn interferes with the intracellular enzyme 3′,5′-cyclic adenosine monophosphate synthetase (cyclic AMP), thereby disrupting the sodium pump system for movement of water and allowing potassium and bicarbonate to seep out of the cell.

Cholera

Parasitic infections. In hot countries, parasitism is endemic. Roundworms, tapeworms, amoebae, hookworms, strongyloides, threadworms, and blood flukes (schistosomiasis) are the main types of parasites. Consequently it is commonplace in these areas for multiple parasite in-

festation to occur in addition to other disorders. This phenomenon, reflecting poverty, lack of education, malnutrition, contaminated drinking water, and inadequate sanitation, is a major factor in chronic ill health and early death.

Parasitic infections. *Roundworms.* Roundworms, or *Ascariasis lumbricoides,* may cause intestinal obstruction if present in sufficient numbers. As they mature from the larval state to the adult worm, they migrate through the body, causing fevers, pneumonitis (lung inflammation), cholangitis (inflammation of the bile ducts), and pancreatitis. Roundworms interfere with the absorption of fat and protein in the intestine, which causes diarrhea. They are eliminated with the administration of piperazine or other anthelmintics, but occasionally surgery is required for obstruction.

Hookworms. Hookworm, or *Ancylostoma duodenale,* infection begins when the worm is in the larval stage. It penetrates the skin, usually of the feet, and migrates during its life cycle through the liver and the lungs, and it attaches to the mucosa of the small intestine where it matures. Hookworms deplete the body of nutrients, and a major effect is severe chronic iron-deficiency anemia. This effect can be corrected with the oral administration of iron, and the number of worms can be controlled with tetrachloroethylene or other anthelmintics.

Life cycle of the hookworm

Threadworms. Threadworms, or *Enterobius vermicularis,* live mainly in the cecum. The adult female migrates at night to the anus and lays eggs on the perianal skin, which causes anal itching. Transmission of the threadworm is fecal–oral, and it can affect an entire family. Threadworms can be eradicated with piperazine or vyprinium embonate.

Tapeworms. The common tapeworms are *Taenia saginata,* found in beef, and *T. solium,* found in pork. Larvae of *Echinococcus granulosus, Diphyllobothrium* species, and some dwarf tapeworms also cause disease. Fertilized ova are passed in feces and are ingested by an intermediary host animal, such as a cow. The embryos migrate to the bloodstream and on reaching muscle or viscera develop into larvae. When the flesh is consumed by humans, the larvae pass into the intestine, where they attach and mature into adult worms. Thus the most common source of infection is inadequately cooked meat. Tapeworms found in beef and pork only give rise to symptoms if their number and size cause intestinal obstruction. *Diphyllobothrium latum,* a fish tapeworm, may cause a severe anemia similar to pernicious anemia, because it consumes most of the vitamin B_{12} in the diet of the host.

Appendicitis. Appendicitis is an inflammation of the vermiform appendix that may be caused by infection or partial or total obstruction. It is a major cause of intra-abdominal pain, principally attacking those younger than 35 years of age. Appendicitis is easily diagnosed and is treated with surgery. Widespread use of antibiotics for upper respiratory and other diseases may have lessened the incidence of the acute form of this disorder, so that more cases of late-developing appendiceal abscess are being reported. Parasitic worms also can contribute to its incidence. Appendicitis occasionally occurs in elderly people, and instances where an abscess forms and bursts require urgent surgery.

Chronic inflammations. Chronic inflammations of the small intestine include tuberculosis and regional enteritis (Crohn's disease). These disturbances are difficult to diagnose in their early stages since their initial symptoms are often vague. General symptoms include low-grade fever, a tendency toward loose stools, weight loss, and episodes of cramping abdominal pain caused by obstruction of the lumen and interference with normal muscular activity by the inflammation of the intestinal wall. Diagnosis is usually made by X ray. There is specific drug therapy for tuberculosis. In Crohn's disease anti-inflammatory, nonspecific drugs are helpful. Surgical excision of the diseased segments of intestine may be necessary.

Crohn's disease

The incidence of Crohn's disease is rising. The disease is largely confined to young women and may reflect the increase in smoking and use of oral contraceptives. About 60 percent of persons with Crohn's disease require surgery because of obstruction of the intestinal lumen and another 20 percent because of fistulation, or connection, between adjacent structures, for example, from the sigmoid colon to the bladder. A combination of repeated surgical excisions from the small intestine and disease of the intestinal wall can result in a severe malabsorptive state. This sometimes requires long-term intravenous (parenteral) nutrition. Crohn's disease tends to affect the colon more often now than previously.

Celiac disease. Celiac disease affects between one in 500 and one in 2,000 persons, depending on the region of the world. The disease is due to an inability to tolerate a fraction of the gluten, a protein present in wheat, rye, barley, and some oats. It is not clear whether the disability is an allergy, with the damage to the mucosa of the small intestine caused by an immune reaction, or whether it is caused by an inability to break down a toxic protein, gluten, to smaller peptide fractions. The existence of a specific enzyme deficiency has not been proved.

Cause of celiac disease

Studies of the immune function of those with celiac disease suggest that at least a major part of the process is a delayed hypersensitivity reaction and that the morphological changes are correlated with the presence of circulating antibodies to gluten. The mucosal reaction results in progressive atrophy, with dwarfing, if not complete disappearance, of the microvilli and villi that line the intestinal tract. This dramatically reduces the area available for absorption, and malabsorptive diarrhea results. The peak frequency is between six and 24 months of age but the disorder may not manifest itself until middle age, or, if mild, may be unnoticed until then. Iron- and folic-acid deficiency anemias, softening of the bones (osteomalacia), and general weakness may be accompanied by a variety of disorders attributable to the nonabsorption of vitamins. Untreated, it is a serious though rarely life-threatening disease after infancy. Diagnosis is established by a biopsy. Withdrawal from the diet of the cereals that contain gluten generally brings about dramatic improvement and disappearance of all symptoms. A few cases require treatment by corticosteroids as well. Untreated celiac disease may be complicated in middle age by malignant lymphoma of the jejunum. A skin condition, dermatitis herpetiformis, seems likely to be a variant of the disease, and some patients respond immediately to a gluten-free regimen.

Tropical sprue. A malabsorption disorder of unknown cause, tropical sprue affects residents and visitors in tropical countries. It is associated with partial atrophy of the mucosa of the small intestine. Its symptoms are diarrhea, anorexia, and fatigue. If the disease is prolonged, anemia caused by malabsorption of vitamin B_{12} develops. Steatorrhea (excess fat in stools) is common, and glucose absorption is impaired. Prolonged treatment with antibiotics, such as tetracycline, and the replacement of vitamins, especially B_{12} and folic acid, are successful.

LARGE INTESTINE

A wide variety of diseases and disorders occur in the large intestine. Imperfect fetal development may result in an anus that has no opening, a defect that requires major plastic surgery to correct. Abnormal rotation of the colon is fairly frequent and occasionally leads to disorders. Unusually long mesenteries (the supporting tissues of the large intestine) may permit recurrent twisting, cutting off the blood supply to the involved loop. The loop itself may be completely obstructed by rotation. Such complications are usually seen in elderly patients and particularly in those with a long history of constipation.

Simple constipation. Brain disease, metabolic failure, or drugs can dull the normal signals that give rise to the urge to defecate. Poor abdominal musculature or a poor pelvic floor, sometimes the result of surgery or childbirth, makes it difficult to mobilize effective pressures to bring about defecation.

Congenital megacolon. A disease that is analogous to achalasia of the esophagus is an idiopathic (the cause being unknown) condition called aganglionic megacolon, or Hirschsprung's disease. It is characterized by the absence of ganglion cells and normal nerve fibres from the distal (or lower) three to 40 centimetres of the large intestine.

Aganglionic megacolon

Neuromuscular transmission is absent from this segment, and peristalsis cannot occur. It is thus a functional obstruction. In 10 percent of cases a larger segment is involved and, on rare occasions, the whole colon. The area of normal intestine above the obstruction works harder to push on the fecal contents, and eventually the muscle of the normal segment thickens. The entire colon thus slowly becomes more and more distended and thick-walled. Diagnosis is made by the microscopic appearances in a deep biopsy of the lower rectum. Various surgical procedures are used to correct the condition.

Acquired megacolon. Acquired megacolon is commonly caused by a combination of faulty toilet training and emotional disorders during childhood, in which the child withholds defecation. This starts a cycle of the administration of increasing amounts of laxatives with, ultimately, damage to the intrinsic innervation in the intestinal wall. A huge, dilated rectum full of feces develops over the years. The impacted feces act as an obstruction, and further fecal material piles up behind, with voluminus dilatation of the whole colon in some cases. The task of the evacuation of the contents of the bowel prior to surgery, if it is required, may require hospitalization for up to three months. The same phenomenon is occasionally encountered in those with schizophrenia and severe depression. It may be related to neurological disorders such as paraplegia, to unrecognized rectal strictures, and to some metabolic disorders. Severe degrees of constipation, often running in families and leading to megacolon, occur, but the cause has not been discovered. Persons with the disorder are often mistakenly regarded as psychoneurotic or malingerers. Resection of the colon and uniting the ileum to the rectum is effective treatment.

Diarrhea. Because water is normally absorbed from the colonic content, principally in the ascending, or right, colon, any inflammatory, neoplastic, or vascular disturbance of that part of the colon usually decreases the firmness of the stool, increases its 24-hour total weight, and produces blood or other evidence of inflammation.

Lactase deficiency

An example of the relation of motor and absorptive defects is shown by those who are deficient in lactase, the enzyme that splits lactose (milk sugar) into its component parts, glucose and galactose. Shortly after drinking milk, such persons usually have severe intestinal cramping, followed later by watery diarrhea. The lactose in the milk is not broken down, and it stays in the lumen of the small intestine, drawing water to it. The increased bulk of fluid and sugar distends the intestine, which then contracts actively. The rapid contractions become crampy, and the material is driven along the intestine into the colon, which cannot absorb the water rapidly enough. The resultant watery, unformed stools are frequently acidic.

Gas. Gas–fluid mixtures do not provide the distribution of peristaltic pressure as smoothly as do fluids alone. When a person is in an upright position, gas diffuses to the uppermost portions of the colon: the right and left "corners." There it is compressed by the contraction of adjacent segments, giving rise to pain that is localized either near the liver and gallbladder or under the diaphragm and heart. This pain can be incorrectly thought to be associated with diseases of these organs whereas it is actually caused by increased gas in the colon. Eating slower to reduce the amount of air ingested, decreasing the intake of carbonated beverages and whipped desserts that contain air bubbles, and avoiding certain gas-producing foods, such as most beans, onions, sprouts, nuts, and raisins, usually help to reduce flatulence.

Diverticula. Arteries penetrate the muscular walls of the colon from its outside covering, the serosa, and distribute themselves in the submucosa. The channels in which these arteries lie may be regarded as potential tunnels for hernias. With aging, and perhaps in persons predisposed to the disorder, these channels become larger. If the peristaltic activity of the colon maintains a high pressure within its lumen, as in patients straining to defecate, the mucous membrane of the colon may be driven slowly into these channels and eventually may follow the arteries back to their site of colonic entrance in the serosa. At such time, the outward-pushing mucosa becomes a budding sac, or diverticulum, on the antimesenteric border of the colon but with a connection to the lumen. In the Western world, multiple colonic diverticula occur in as many as 30 percent of persons older than 50 years. Diverticula are particularly common in those whose diets are deficient in fibre (roughage), and they are rare in countries where high-fibre diets are usual. Hypertrophy (increase in size and mass) of the muscle fibre of the colon, especially in the sigmoid region, precedes or accompanies diverticulosis; this is especially apparent in the diverticulosis in middle-aged persons as opposed to that in the elderly.

Diverticulosis

The principal dangers of diverticulosis are massive hemorrhage and inflammation. Hemorrhage results from the action of hard stools against the small arteries of the colon that are exposed and unsupported because of diverticula. As the arteries age, they become less elastic, less able to contract after bleeding begins, and more susceptible to damage. Diverticulitis, on the other hand, occurs when the narrow necks of the diverticula become plugged with debris or inedible foodstuff and bacteria, uninhibited by the usual motor activity that keeps the intestine clean, proliferate in the blind sacs. When the sacs enlarge, the adjacent intestinal wall becomes inflamed and irritable, muscle spasms occur, and the patient experiences abdominal pain and fever. If the sacs continue to enlarge, they may rupture into the peritoneum, giving rise to peritonitis, or an inflammation of the peritoneum. More commonly they fix themselves to neighbouring organs and produce localized abscesses, which may prove difficult to treat surgically. Mild diverticulitis responds well to conservative treatment and to antibiotics; massive hemorrhages often require emergency surgery. Recurrent diverticulitis requires resection of the affected area of the colon.

Abscesses. Abscesses (cavities of pus formed from disintegrating tissue) in the perianal area are common complicating features of many diseases and disorders of the large intestine. Fungal infections of the moist and poorly cleansed area around the anus are common and permit the maceration (or gradual breaking down) of tissue and the invasion by bacteria from the skin and colon. In a diabetic, who is susceptible to skin infection, scrupulous perianal hygiene is very important.

Bacterial infections. The colon may become inflamed because of invasion by pathogenic, or disease-causing, bacteria or parasites. A variety of species of *Shigella,* for example, attack the mucous membrane of the colon and produce an intense but rather superficial hemorrhage. In infants and in the elderly, the amount of fluid and protein lost by the intense inflammatory response may be fatal, but ordinarily such symptoms are less serious in otherwise healthy persons. *Salmonella* species, responsible for severe generalized infections originating from invasion of the small intestine, may damage the lymph follicles of the colon, but they do not produce a generalized inflammation of the colon (colitis). The cytomegalic virus can cause a severe colitis, producing ulcerations. Lymphopathia venereum causes a more generalized and superficial colitis.

Food residues provide an excellent culture medium for bacteria, and the interior of the colon is a nearly ideal environment for their growth. The most important parasite producing disease in the human colon is the protozoan *Entamoeba histolytica.* This widely distributed parasite enters the human digestive tract via the mouth and lodges in the cecum and ascending colon. This usually results in irritability of the right colon and failure to absorb water properly, so that intermittent, watery diarrhea ensues. The amoebas undermine the mucosal coat and may create large ulcerations that bleed impressively. Stools contain blood, but there is little pus or other evidence of reaction by the colon to the invading organism. In more generalized amoebic colitis, the rectum and sigmoid colon are invaded by *E. histolytica,* which manifest their presence by numerous discrete ulcerations separated from each other by a relatively normal-appearing mucous membrane. The amoebas may enter the portal circulation and be carried to the liver, where abscesses form and sometimes rupture into the chest or the abdominal cavity. Immunologic tests of the blood may help in diagnosis. After identification

Amoebic disease

of the parasites by direct smears from the margin of the ulcers, or from the stools, treatment is with a combination of amoebicidal drugs and a broad-spectrum antibiotic—*i.e.*, an antibiotic that is toxic to a wide variety of parasites—usually metronidazole and tetracycline.

Colitis. The most common form of chronic colitis (inflammation of the colon) in the Western world, ulcerative colitis, is idiopathic (*i.e.*, of unknown cause). It varies from a mild inflammation of the mucosa of the rectum, giving rise to excessive mucus and some spotting of blood in the stools, to a severe, sudden, intense illness, with destruction of a large part of the colonic mucosa, considerable blood loss, toxemia and, less commonly, perforation. The most common variety affects only the rectum and sigmoid colon and is characterized by diarrhea and the passage of mucus. The disorder tends to follow a remitting-relapsing course. About 15 percent of cases of all colitis involve extension of the disease beyond the area initially affected, with an increase in severity. Where the destruction has been extensive, there is a risk of malignancy 10 to 20 years after the onset of the disease.

Crohn's disease. The cause of Crohn's disease is unknown. Apart from the greater tendency for fistulas to form and for the wall of the intestine to thicken until the channel is obstructed, it is distinguishable from ulcerative colitis by microscopic findings. In Crohn's disease, the maximum damage occurs beneath the mucosa, and lymphoid conglomerations, known as granulomata, are formed in the submucosa. Crohn's disease attacks the perianal tissues more often than does ulcerative colitis. Although these two diseases are not common, they are disabling.

Sites of damage

Because there is no specific etiology, a combination of anti-inflammatory drugs, including corticosteroids and aminosalicylic acid compounds, is used to treat Crohn's disease. The drugs are effective both in treating acute episodes and in suppressing the disease over the long term. Depending on the circumstances, hematinics, vitamins, high-protein diets, and blood transfusions are also used. Surgical resection of the portion of the large bowel affected is often done. The entire colon may have to be removed and the small intestine brought out to the skin as an ileostomy, an opening to serve as a substitute for the anus. In ulcerative colitis, as opposed to Crohn's disease, the rectal muscle may be preserved and the ileum brought through it and joined to the anus.

Tumours of the colon are usually polyps (growths from the mucous membranes) or cancers. The tendency of some persons to form polyps is strikingly exemplified in the rare disorder known as familial polyposis, in which the colon may be studded with hundreds or thousands of small polyps. Because a colon that produces so many polyps eventually produces cancers as well, these colons should be removed surgically as soon as the diagnosis is made. The rectum may be left, but a visual examination of the residual mucosa must be made twice yearly to detect signs of early cancerous change. Another peculiar form of polyp is the villous adenoma, often a slowly growing, fernlike structure that spreads along the surface of the colon for some distance. It can recur after being locally resected, or it can develop into a cancer.

Cancer. In the West, cancer of the colon is a more common tumour than is cancer of the stomach, and it occurs about equally in both sexes. Symptoms are highly variable, the main feature being blood in the stools, but this may be detectable only by chemical testing. Cancers compress the colonic lumen to produce obstruction, they attach to neighbouring structures to produce pain, and they perforate to give rise to peritonitis. Cancers also may metastasize to distant organs before local symptoms appear. Nevertheless, the prognosis for patients with this tumour is considerably better than it is for cancer of the stomach. About half the patients who have a colonic cancer removed surgically live at least five years. A colostomy is required for some patients, in which an opening is made from the colon to the skin, where the fecal contents are extruded. After the colon has been removed partially, it is possible to join the terminal ileum or the remnant colon directly to the anal canal. A reservoir also can be fashioned out of the terminal ileum and placed inside the rectum muscle from which the inflamed mucosa has been removed. This functions as a normal rectum and with retained sphincters at the anus can render the patient continent, although there usually are three or four movements daily.

Symptoms of colon cancer

Anal disorders. Anorectal disorders related to defecation are more common in the Western world than elsewhere. Whether this distribution is related to diet, exercise, personal hygiene, or to social customs that inhibit the natural gratification of the urge to defecate is not clear. These disorders usually take the form of fissures (cuts or cracks in the skin or mucous membrane) at the junction of the anal mucous membrane with the skin between the thighs. If such fissures become chronically infected and resistant to treatment by sitz baths and local medication, they may require surgical correction. Anal fistulas sometimes occur as complications of serious bowel disease, as in tuberculosis or Crohn's disease of the bowel, or in certain parasitic diseases. A more general disorder is the enlargement of veins of the rectum and anus to form external or internal hemorrhoids. Many adults in the West have such venous enlargements, but only a small number suffer serious symptoms from their presence. Hemorrhoids protrude, are associated with anal itching and pain, and bleed, especially when they come in contact with hard stools. These symptoms generally can be controlled by conservative measures, but occasionally they persist or cause so much distress that surgical removal of the enlarged and dilated veins is necessary.

Hemorrhoids

In the past, poor obstetrical and postnatal care resulted in a severe loss of support of the pelvic floor in parturient women; prolapse, or downward displacement, of the rectum, as well as of the uterus and bladder, was common. Such complications have largely been eliminated except in conditions such as fibrocystic disease of the pancreas in children or in certain neurological disorders in aged persons. (W.S.)

LIVER

A variety of agents, including viruses, drugs, environmental pollutants, genetic disorders, and systemic diseases, can affect the liver. The resulting disorders usually affect one of the three functional components of the liver: the hepatocyte (liver cell) itself, the bile secretory (cholangiolar) apparatus, or the blood vascular system. Although an agent tends to cause initial damage in only one of these areas, the resulting disease may in time also involve other components. Thus, although viral hepatitis (inflammation of the liver) predominantly affects hepatocytes, it commonly leads eventually to canalicular damage.

Most acute liver diseases are self-limited, and liver functioning returns to normal once the causes are removed or eliminated. In some cases, however, the acute disease process destroys massive areas of liver tissue in a short time, leading to extensive death (necrosis) of hepatic cells and often to death of the patient. Hepatitis may result from viral infections or toxic damage from drugs or poisons. When acute hepatitis lasts for six months or more, a slow but progressive destruction of the surrounding liver cells and bile ducts occurs, a stage called chronic active hepatitis. If hepatocellular damage is severe enough to destroy entire acini (clusters of lobules), they are often replaced with fibrous scar tissue. Bile canaliculi and hepatocytes regenerate in an irregular fashion adjacent to the scar tissue and result in a chronic condition called cirrhosis of the liver. Where inflammatory activity continues after the onset of cirrhosis, the disorderly regeneration of hepatocytes and cholangioles may lead to the development of hepatocellular or cholangiolar cancer.

Chronic active hepatitis

Acute hepatocellular hepatitis. Although a number of viruses affect the liver, including the cytomegalovirus of infancy and childhood and the Epstein-Barr virus of infectious mononucleosis, there are three distinctive transmissible viruses that are specifically known to cause acute damage to liver cells: hepatitis virus A (HAV), hepatitis virus B (HBV), and hepatitis virus non-A, non-B (NANB).

The hepatitis A virus is transmitted almost exclusively by the fecal–oral route, and it thrives in areas where sanitation

and food handling are poor and hand washing is infrequent. Hepatitis A virus proliferates in the intestinal tract during the two weeks following the onset of symptoms, but it then disappears. Many infected persons are unaware of being ill, since their disease remains asymptomatic or quite mild. The incubation period of HAV infections, from viral ingestion to the onset of symptoms, averages four to five weeks. Acute illness in an otherwise healthy pregnant woman does not appear to have adverse effects upon the fetus. Persons can become passively immunized against hepatitis A attacks for several months with a single injection of immunoglobulin, a product made from pools of 100 or more donor plasmas. Persons can be actively immunized to HAV by acquiring the virus subsequent to becoming passively immunized, but such infections are either inapparent or very mild. An active vaccine is not available, and there are no carriers of the virus.

Incubation period of HAV infections

Hepatitis B virus is present throughout the world in asymptomatic human carriers who may or may not have ongoing liver disease. Formerly, the disease was widely spread by the transfusion of whole blood or blood products, such as the cryoprecipitate used in the treatment of hemophilia. Since the markers of infection have become so readily identifiable, this mode of transmission is much less common, comprising only about 10 percent of cases, compared with 60 percent in the past. Hepatitis B virus is still transmitted in some blood specimens because the levels of virus particles present may be too low to be detected. Virus particles in carriers are found in bodily secretions, especially saliva and sexual emissions, as well as in blood. The incidence of B antigens is high among persons engaging in promiscuous sexual activity, drug addicts who share syringes, health care workers, and infants of mothers who are carriers. Many newly infected persons develop the acute disease within three weeks to six months after exposure, while some develop an asymptomatic form of hepatitis that may appear only as chronic disease years later. Others eliminate the virus completely without any symptoms beyond the appearance of antibodies to surface antigen, while still others become carriers of surface antigen and thus presumably are infective to others.

There are two methods of preventing hepatitis B: passive immunization, through the use of a specific immunoglobulin derived from patients who have successfully overcome an acute HBV infection; and active immunization, through the injection of noninfective, purified HBV surface antigen. The first method is used following specific exposures that carry a high risk of infection, such as using needles contaminated with HBV particles, the ingestion of body products likely to be infected, or the birth of an infant to a surface-antigen-positive mother. The second method, active immunization, is used for those who belong to groups with a high risk of HBV infection, such as children living in endemic areas, medical personnel in high-risk specialties, drug addicts, sexually promiscuous persons, and family groups living close to known carriers. Active immunization, involving a series of three injections of vaccine over a period of three to six months, has been shown to confer a high degree of resistance to infection.

Groups at high risk

Non-A, non-B hepatitis virus has not been isolated, so that the markers of infection and of immunity are not available. Because of this, NANB is the major cause of posttransfusion hepatitis, and it appears with a frequency of three to six cases per 1,000 transfusions of blood prescreened for HBV. The average incubation period of the disease is about seven weeks, and an acute attack of NANB hepatitis is usually less severe than acute hepatitis B. Non-A, non-B hepatitis, however, is more likely to become chronic than is hepatitis B, and it may recur episodically with acute flares.

The symptoms characteristic of the acute hepatitis caused by the HAV, HBV, and NANB viruses are essentially indistinguishable from one another. Patients often complain of a flulike illness for several days, with chills, variable degrees of fever, headache, cough, nausea, occasional diarrhea, and pronounced malaise. Abdominal pain caused by swelling of the liver is a common complaint. As many as half of the infected patients develop only mild symptoms or none at all. A small percentage of patients, especially those with HBV infections, may develop hives, painful skin nodules, acute arthritis, or urinary bleeding caused by the deposition of large immune antigen–antibody complexes in the small blood vessels of adjacent organs. After several days or a week of such symptoms, jaundice commonly develops. At times the jaundice is so mild that it is not noticed by patients, although they often do note that the urine has become dark amber in colour because of the high levels of water-soluble bilirubin transmitted to the kidneys by the bloodstream.

The onset of jaundice usually brings with it a marked improvement in other symptoms (see below, *Biliary tract: Jaundice*). Jaundice lasts about two weeks but may continue for several months, even in those who have complete recovery. Some patients complain of itching during this period, and they notice the light colour of their stools. These symptoms probably result from the compression of bile canaliculi and intralobular bile ducts by the swelling of hepatocytes and Kupffer cells. The changes result in the reduced secretion of bile pigments into the biliary system, their reflux into the bloodstream, and the deposition of bile salts and other biliary constituents in the skin and subcutaneous tissues, a condition called obstructive jaundice. After the phase of jaundice subsides, almost all patients with hepatitis A, and at least 90 percent of those with hepatitis B, recover completely.

The onset of jaundice

Aside from jaundice, the physical examination of patients with acute viral hepatitis may reveal nothing more than the swelling of lymph nodes in the neck. Many patients have detectable enlargement and, at times, tenderness of the liver. Some also show an enlarged spleen. Signs of confusion or disorientation indicate severe damage to the liver. The diagnosis of hepatitis is confirmed by blood tests that show marked elevations of enzymes (aminotransferases) released from damaged liver cells and, at times, by the presence of viral antigens or acute viral antibodies (IgM).

A small number, perhaps 1 percent, of patients with viral hepatitis, especially the elderly, develop a sudden, severe (fulminant) form of hepatic necrosis that can lead to death. In this form of the disease jaundice increases to high levels during the first seven to 10 days, spontaneous bleeding occurs because of reductions of blood-clotting proteins, and irrational behaviour, confusion, or coma follow, caused by the accumulation in the central nervous system of the breakdown products of protein normally metabolized by the liver. Beyond supportive measures there is no effective treatment of fulminant hepatic failure.

Acute hepatitis also may be caused by the overconsumption of alcohol or other poisons, such as commercial solvents (*e.g.*, carbon tetrachloride), acetaminophen, and certain fungi. Such agents are believed to cause hepatitis when the formation of their toxic intermediate metabolites in the liver cell (phase I reactions) is beyond the capacity of the hepatocyte to conjugate, or join them with another substance for detoxification (phase II reactions) and excretion. As long as the levels of these agents are small enough to permit complete phase I and phase II reactions, there is no damage to the liver cell.

Other causes of acute hepatitis

Acute canalicular (cholestatic) hepatitis. This form of hepatitis is most commonly caused by certain drugs, such as chlorpromazine, that lead to idiosyncratic reactions or, at times, by hepatitis viruses. The symptoms are generally those of biliary obstruction and include itching, jaundice, and light-coloured stools. Drug-induced cholestasis almost invariably disappears within days or weeks after exposure to the agent is discontinued. Acute congestive liver disease usually results from the sudden engorgement of the liver by fluids after congestive heart failure. The liver may enlarge and become tender. The levels of hepatocytic enzymes in the blood are often greatly increased, and recovery is rapid once the heart failure improves. Jaundice is uncommon in acute hepatic congestion.

Chronic active hepatitis. The result of unresolved acute injury, chronic active hepatitis is associated with ongoing liver damage. A milder form of chronic disease, called persistent hepatitis, does not appear to lead to progressive liver damage despite evidence of a continuing mild inflammation. These conditions may result from viral hepatitis,

drug-induced hepatitis, autoimmune liver diseases (lupoid hepatitis), or congenital abnormalities. A prominent autoimmune liver disease is Wilson's disease, which is caused by abnormal deposits of large amounts of copper in the liver. Granulomatous hepatitis, a condition in which localized areas of inflammation (granulomas) appear in any portion of the liver lobule, is a type of inflammatory disorder associated with many systemic diseases, including tuberculosis, sarcoidosis, schistosomiasis, and certain drug reactions. Granulomatous hepatitis rarely leads to serious interference with hepatic function, although it is often chronic.

Chronic active viral hepatitis cannot be treated effectively and the course of the disease is usually slow but relentlessly progressive. Cirrhosis of the liver, and occasionally hepatocellular cancer, usually result from a gradual loss of liver function. Chronic active hepatitis that is the result of autoimmune disorders usually responds to the administration of adrenal corticosteroids, which moderate the inflammatory reaction.

Cirrhosis. The end result of many forms of chronic liver injury is cirrhosis, or scarring of liver tissue in reponse to previous acinar necrosis and irregular regeneration of liver nodules and bile ducts. Among the congenital disorders producing cirrhosis are Wilson's disease, hemochromatosis (over-deposition of iron pigment), cystic fibrosis, biliary atresia (congenital absence of a part of the bile ducts), and alpha$_1$-antitrypsin deficiency, or the congenital absence of a proteolytic enzyme inhibitor that results in the accumulation of abnormal forms of carbohydrate in hepatocytes. In the West, cirrhosis of the liver most commonly results from chronic heavy intake of alcohol. Chronic viral hepatitis is probably the leading cause of cirrhosis in underdeveloped countries. Primary biliary cirrhosis, a widespread, though uncommon, autoimmune inflammatory disease of bile ducts, is a disorder primarily affecting middle-aged and older women. The inflammation leads to necrosis and gradual disappearance of bile ducts over a period of one or more decades. Secondary biliary cirrhosis results from chronic obstruction or recurrent infection in the extrahepatic bile ducts caused by strictures, gallstones, or tumours. Infestation of the biliary tract with a liver fluke, *Clonorchis sinensis,* is a cause of secondary biliary cirrhosis in Asia. Cirrhosis occasionally is the result of chronic vascular congestion of the liver in persons with prolonged heart failure and in those with chronic obstruction of the hepatic veins caused by benign blood clots or metastatic cancer. Symptoms of cirrhosis are usually absent during the early stages of the disease. Occasionally, cirrhosis is detected during a physical examination when an enlargement of the liver, spleen, or veins in the upper abdominal wall is found. More often, patients develop symptoms related either to the failure of the liver to perform its functions or to complications caused by the circulatory changes that a cirrhotic liver imposes on the venous blood flow from the intestinal tract (portal hypertension). Thus, common symptoms include jaundice, resulting from reduced passage of conjugated bilirubin into the biliary tract; increased bleeding, from sequestration of blood platelets in a congested spleen; or the deficient production of short-lived coagulation proteins by the liver. In males, there may be certain changes in the skin, such as the appearance of small spider-like vascular lesions on the hands, arms, or face, a marked reddening of portions of the palms, or enlargement of the breast or reduction in testicular size. These symptoms are believed to occur because of the liver's inability to metabolize the female sex hormones normally produced by the body. The gradual accumulation of fluid in the abdominal cavity (ascites), sometimes accompanied by swelling of the ankles, is attributable to portal hypertension and to reduced hepatic production of albumin, while failure of the liver to metabolize amino acids and other products of protein digestion may lead to the state of confusion called hepatic encephalopathy. Loss of appetite, reduction of muscle mass, nausea, vomiting, abdominal pain, and weakness are other symptoms of hepatic cirrhosis. Diabetes in a patient with cirrhosis is caused by hemochromatosis (excessive deposition of iron in tissues, especially in the liver and pancreas), since iron deposits compromise the production of insulin by the islets of Langerhans in the pancreas. Severe spastic disorders of the muscles in the limbs, head, and face suggests the presence of Wilson's disease, especially if there is a family history, since the copper deposits characteristic of that disorder are toxic to the liver and to structures in the base of the brain. A history of chronic lung infections or of progressive obstructive lung disease may be present in patients with cystic fibrosis or a deficiency of alpha$_1$-antitrypsin.

Congenital disorders producing cirrhosis

A diagnosis of cirrhosis is confirmed by blood tests that show an elevated concentration of hepatocytic enzymes, reduced levels of coagulation proteins, elevated levels of bilirubin, and, most importantly, reduced amounts of serum albumin (a major protein of human blood plasma) and increases in serum globulin (a specific group of proteins found in blood plasma and including immunoglobulins). Although other tests may also be abnormal in patients with acute liver disease, serum albumin levels are usually not reduced in the acute stage of the disease because that protein is rather long-lived, up to one month, and levels do not decrease until the liver disease becomes chronic. Elevated levels of serum iron or copper support a diagnosis of hemochromatosis or Wilson's disease, respectively, while a positive test for serum antibodies to cellular mitochondria is associated almost solely with primary biliary cirrhosis. The presence of HBV surface antigen or of delta agent suggests posthepatic cirrhosis. A percutaneous needle biopsy of the liver is the most valuable diagnostic test, since this procedure makes available an actual specimen of liver tissue for microscopic examination. Treatment of cirrhosis of the liver never results in a completely normal organ, since the process of scarring and nodular regeneration is permanent. The process itself, however, can be prevented or its progress halted by managing the precipitating factors of the disease.

Confirmation of cirrhosis

Complications of advanced liver disease. *Hepatic encephalopathy.* Hepatic encephalopathy refers to the changes in the brain that occur in patients with advanced acute or chronic liver disease. If liver cells are damaged, certain substances that are normally cleansed from the blood by the healthy liver are not removed. In the case of cirrhosis, blood from the portal system is not exposed to functioning hepatocytes because it is transported through blood vessels in the liver that do not run through regenerating nodules of hepatocytes, owing to the atypical growth inherent in the cirrhotic process. These products of cell metabolism are primarily nitrogenous substances derived from protein, especially ammonia, or possibly certain straight-chain fatty acids. They pass to the brain where they damage functioning nervous tissue or subvert the actions of neurotransmitters, chemical messengers that carry impulses from one brain cell to another. In acute diseases, the brain exposed to those agents becomes swollen to the point where normal breathing may cease. Chronic exposure can lead to destruction of nerve cells with replacement by scar tissue (gliosis). A patient with chronic hepatic encephalopathy may develop progressive loss of memory, disorientation, untidiness, and muscular tremors, leading to a form of chronic dementia. The ingestion of protein invariably aggravates these symptoms.

Gliosis

The treatment of hepatic encephalopathy involves, first, the removal of all drugs that require detoxification in the liver and, second, the reduction of the intake of protein. Ammonia is a potentially harmful by-product of digestion, and its concentration in the blood can be lowered either through the reduction of intestinal bacteria by the administration of enteric antibiotics, which reduce the production of ammonia in the colon, or by the administration of lactulose, a nonabsorbable carbohydrate whose by-products make the contents of the colon more acidic, creating an environment that reduces the diffusion of ammonia from the intestinal lumen to the portal blood vessels.

Portal hypertension. Portal hypertension, the increased pressure in the portal vein and its tributaries that is the result of impediments to venous flow into the liver, is brought about by the scarring characteristic of the cirrhotic process. The increased pressure causes feeders of the portal vein to distend markedly, producing varices, or

dilations of the veins. When varices are located in superficial tissues, they may rupture and bleed profusely. Two such locations are the lower esophagus and the perianal region. Esophageal varices are likely to bleed most heavily, and, because of the reduced blood flow in the liver that results and the large amount of protein contained in the blood that is shed into the intestines, profuse bleeding from esophageal varices is frequently associated with the onset of hepatic encephalopathy or coma. Because of their location at the lower end of the esophagus or the upper portion of the stomach, bleeding from varices is often difficult to control. It may stop spontaneously, but it is likely to recur. Considerable success in stemming such hemorrhage and preventing its recurrence has been achieved by the injection of sclerosing (hardening) agents into varices during endoscopic visualization. If variceal bleeding persists and if the patient can withstand a long and complex operative procedure, surgical formation of a shunt, or artificial passageway, from the portal vein or one of its feeders to a systemic abdominal vein, such as the vena cava or the left renal vein, may be done.

Esophageal varices

Ascites. The accumulation of fluid in the abdominal cavity, or ascites, is related to portal hypertension, significant reduction in serum albumin, and renal retention of sodium. When albumin levels in blood are lower than normal, there is a marked reduction in the force that holds plasma water within the blood vessels and normally resists the effects of the intravascular pressure. The resulting increase in intravascular pressure, coupled with the increased internal pressure caused by the portal venous obstruction in the liver, leads to massive losses of plasma water into the abdominal cavity. The associated reduction of blood flow to the kidneys causes increased elaboration of the hormone aldosterone, which, in turn, causes the retention of sodium and water and a reduction in urinary output. In addition, because the movement of intestinal lymph into the liver is blocked by the cirrhotic process in the liver, the backflow of this fluid into the abdominal cavity is greatly increased. The volume of abdominal ascites in adults with cirrhosis may reach levels as great as 10 to 12 litres (10.6 to 12.7 quarts). Ascitic fluid may accumulate in the scrotum and in the chest cavity, where its presence, combined with the upward pressure on the diaphragm from the abdominal fluid, may severely affect breathing. Appetite also is often reduced by the abdominal distention.

Treatment of cirrhotic ascites

The treatment of cirrhotic ascites begins with the removal of enough fluid directly from the abdomen by needle puncture to ease discomfort and breathing. Patients are placed on diets low in salt (sodium chloride), and they are given diuretic drugs to increase the output of water by the kidneys. If these measures do not control massive ascites, ascites can be drained internally into the general venous blood system by running a plastic tube from the abdominal cavity, under the skin of the chest, into the right internal jugular vein of the neck (peritoneovenous shunt of LeVeen).

Hepatorenal syndrome. A progressive reduction in kidney function that often occurs in persons with advanced acute or chronic liver disease, hepatorenal syndrome probably results from an inadequate perfusion of blood through the cortical (outer) portions of the kidneys, where most removal of waste products occurs. In some instances, hepatorenal syndrome is precipitated by marked reductions in blood volume that result from a low concentration of water in the blood. Hemorrhages also can reduce kidney function by leading to damage of renal tubules. Finally, with advanced hepatocytic dysfunction, a spasm of blood vessels in the renal cortex can occur, often with good blood flow to the rest of the kidney. This spasm results in progressive failure in kidney function and often leads to death. The kidneys themselves are frequently undamaged structurally. Treatment of patients with volume depletion and tubular damage often may lead to significant improvement in kidney function.

Tumours. Although not uncommon, cancer originating in the liver, usually in hepatocytes and less frequently in cells of bile duct origin, is rare in the West and is almost always associated with active cirrhosis, particularly the form found in patients with chronic hepatitis. The survival rate from liver cancer is small. In certain underdeveloped countries, especially in tribal Africa, the incidence of this malignancy is high and is a major cause of death in the population. Most of these cases appear to stem from the prevalence of chronic viral hepatitis or the chronic presence of viruses in the blood (viremia) caused by hepatitis B. Long exposure to certain environmental poisons, such as vinyl chloride or carbon tetrachloride, has also been shown to lead to hepatic cancer.

Incidence in underdeveloped countries

Cancers arising elsewhere in the body, particularly in abdominal organs, lungs, and lymphoid tissue, commonly lead to metastatic cancer in the liver and are by far the most frequent type of hepatic malignancy. Usually, when such metastases are found, the primary tumour has advanced beyond the stage where it can be removed surgically. Various benign types of tumours and cysts arise from certain components of the liver, such as the hepatocytes (adenomas) or blood vessels (hemangiomas). While the cause of these lesions is not always clear, hepatic adenomas are associated with the prolonged use of female sex hormones (estrogens). Symptoms of benign tumours depend mainly on their size and their position in relation to the surface of the liver. If they enlarge significantly, patients may note pain or sensations of heaviness in the upper abdomen. When benign tumours are located close to the surface of the liver, they may rupture through the capsule and bleed freely into the abdominal cavity. Surgery is then required.

Benign cysts (tissue swellings filled with fluid) in the liver may occur as congenital defects or as the result of infections from infestation of the dog tapeworm (*Echinococcus granulosus*). Abscesses on the liver result from the spread of infection from the biliary tract or from other parts of the body, especially the appendix and the pelvic organs. Specific liver abscesses also result from infections with the intestinal parasite *Entamoeba histolytica.* Abscesses usually respond well to treatment with specific antibiotics, although surgical drainage is required in some cases.

BILIARY TRACT

Gallstones. Cholelithiasis, or the formation of gallstones in the gallbladder, is the most common disease of the biliary tract. Gallstones are of three types: stones containing primarily calcium bilirubinate (pigment stones); stones containing 25 percent or more of cholesterol; and stones composed of variable mixtures of both bilirubin and cholesterol (mixed gallstones). Purely pigment stones are more common in certain parts of Asia than in the West, and they are prone to occur in persons who suffer from forms of anemia caused by the rapid destruction of red blood cells (hemolysis). Hemolytic disease results from the hereditary or acquired acquisition of abnormal forms of hemoglobin or from abnormalities of the red blood cell membrane in disorders such as sickle-cell anemia, thalassemia, or acquired hemolytic anemias. Increased destruction of red blood cells leads to abnormally large amounts of bilirubin, the hemoglobin derivative, in the liver and the consequent secretion into the biliary tract of increased amounts of the water-soluble conjugate, bilirubin diglucuronide, a pigment that is normally secreted in the urine. In the biliary tract, particularly in the gallbladder, some of this bilirubin diglucuronide is broken down by bacterial or mucosal enzymes into water-insoluble bilirubin, which then tends to form stones. There are two types of pigment stones, black and brown. Black stones tend to form mainly in the gallbladder and occur in sterile bile, while brown stones may occur in any part of the biliary tract in patients with chronic biliary infections and varying degrees of stasis. The reasons for the increased incidence of pigment stones among persons with cirrhosis of the liver and the aged are not clear, although increased red blood cell destruction may play a part. The occurrence of pigment stones is slightly more common in women.

Types of gallstones

Cholesterol and mixed cholesterol-bilirubinate stones occur when the proportion of cholesterol in bile exceeds the capacity of bile acids and lecithin to contain the total amount of cholesterol in micellar colloidal solution. When this critical micellar concentration is surpassed and the

solution is saturated, crystalline particles of cholesterol are formed. The resulting gallstones contain large amounts of crystalline cholesterol and smaller quantities of calcium bilirubinate. Pure cholesterol gallstones are rare.

Cholesterol gallstones occur about twice as frequently in women as they do in men, and at younger ages. Those at increased risk of cholesterol gallstones include persons who are obese, on diets high in caloric content or in cholesterol, diabetic, or taking female sex hormones. Each of these factors favours increased concentrations of cholesterol in bile. In addition, some persons are unable, for genetic reasons, to convert sufficient amounts of cholesterol to bile acids, thus favouring the increased formation of stones. Some illnesses reduce the capacity of the lower small intestine to reabsorb bile acids, leading to deficits of bile acids that cannot be overcome by hepatic synthesis alone. During pregnancy, the ratio of chenodeoxycholic acid to cholic acid in hepatic bile is reduced, thus making bile more prone to produce stones (lithogenic). Decreased flow of bile in the gallbladder, a condition that occurs late in pregnancy, in persons on diets low in fat, and among certain diabetics, also appears to favour the formation of cholesterol stones. Occasionally, some persons produce lithogenic bile, which results from reduced concentrations of phospholipids.

Risk factors

Symptoms are likely to be absent in about half of all patients who have gallstones. When they do appear, symptoms are caused by transient or prolonged obstruction of a portion of the biliary tract, most commonly the cystic duct at the point where it emerges from the gallbladder. This obstruction leads to painful contraction of the gallbladder, swelling of its wall, and acute inflammation (cholecystitis). During an attack of cholecystitis, patients are often found to have fever, sharp pain in the abdomen (which also may be felt in the right shoulder region), tenderness over the region of the gallbladder, and elevations of the white blood cell count. If the obstruction of the neck of the gallbladder is prolonged, bacterial infections may appear, leading to formation of an abscess. Patients with bacterial infections in the gallbladder or bile ducts commonly have severe rigours, or shaking chills, with high, spiking fevers. Jaundice does not occur with gallstone complications unless the stones become impacted and obstruct the common bile duct, thus slowing or interrupting the free passage of bile from the liver to the intestine. This jaundice is associated with a marked lightening of stool colour, caused by the absence of bile pigments in the intestine, and a change in the colour of urine to a dark amber, caused by large quantities of conjugated bilirubin.

Cholecystitis

Gallstone disease is easy to diagnose since calculi in the gallbladder can be easily detected by ultrasonography. Enlargement of the gallbladder and bile ducts (resulting from obstruction) also can be detected by this method.

As many as one-half of all persons with gallstones never have serious symptoms or complications. Thus, if gallstones are discovered on routine examination or during abdominal surgery for other reasons, and if the patient has no history of gallstone symptoms, nothing probably needs to be done. The situation is different, however, in persons who are clearly symptomatic or who are suffering acute complications, such as cholecystitis or abscesses. The traditional treatment in these cases is surgical removal of the diseased gallbladder and exploration of the bile ducts by X rays at the time of surgery for stones. The risks of this surgery are extremely small, although they do increase considerably in persons with acute complications and in older persons. Once the gallbladder and ductal stones are removed, there is little likelihood that cholesterol or black pigment stones will recur, although brown pigment stones may occasionally recur in the bile ducts after cholecystectomy.

Many cholesterol gallstones can be dissolved without surgery as long as the gallbladder has retained its ability to concentrate bile and the cystic duct is unobstructed. This is accomplished by regular oral administration of the bile acids chenodeoxycholic acid or ursodeoxycholic acid. The ingestion of these acids increases the amount of bile acids in hepatic bile and increases the ratio of bile acids to cholesterol, thus changing the bile from lithogenic to nonlithogenic. This medication must be continued for more than one year for the cholesterol gallstones to be completely dissolved and then continued permanently at reduced doses to prevent the reappearance of stones. Only a small percentage of patients are willing to undergo this permanent treatment, and the use of bile acids is confined either to those who strongly oppose surgery or those for whom surgery imposes great risk. Pigment stones do not respond to bile acid therapy.

Other biliary tract disorders. Cancer of the biliary tract is rare but may occur in almost any area, including the gallbladder, the hepatic ducts, the common bile duct, or the ampulla of Vater. About 90 percent of persons with primary cancer of the gallbladder also have gallstones. The risk of cancer in persons with gallstones, however, is very low (about 1 percent or less). In cancer of the bile duct, congenital cysts and parasitic infections, such as liver flukes, seem to lead to increased risks. Persons with extensive chronic ulcerative colitis also show a greater than normal incidence of bile duct carcinoma. Obstructive jaundice is usually the first sign of biliary tract cancer. Surgery is the only treatment, and the chances of cure are very small. Because most biliary duct cancers grow very slowly, physicians often try to relieve the obstructive jaundice by passing tubular stents (supporting devices) through the obstruction, using endoscopic or radiologic techniques.

Cancer

Postcholecystectomy syndrome comprises painful attacks, often resembling preoperative symptoms, that occasionally occur following the surgical removal of gallstones and the gallbladder. These attacks may be related to intermittent muscular spasms of the sphincter of Oddi or of the bile ducts. Drugs are used to help prevent or reduce these spasms.

Jaundice. Jaundice, or yellowing of the skin, scleras, and mucous membranes, occurs whenever the level of bilirubin in the blood is significantly above normal. This condition is evident in three different types of disorders, more than one of which may be present simultaneously in a single person. The first type, unconjugated, or hemolytic, jaundice, appears when the amount of bilirubin produced from hemoglobin by the destruction of red blood cells or muscle tissue (myoglobin) overwhelms the normal capacity of the liver to transport it or when the ability of the liver to conjugate normal amounts of bilirubin into bilirubin diglucuronide is significantly reduced by inadequate intracellular transport or enzyme systems. The second type, hepatocellular jaundice, arises when liver cells are damaged so severely that their ability to transport bilirubin diglucuronide into the biliary system is reduced, allowing some of this yellow pigment to regurgitate into the bloodstream. The third type, cholestatic, or obstructive jaundice, occurs when essentially normal liver cells are unable to transport bilirubin either through the hepatocytic-bile capillary membrane, because of damage in that area, or through the biliary tract, because of anatomical obstructions (atresias, gallstones, cancer).

Three types of jaundice

Unconjugated jaundice. Unconjugated jaundice, or hemolytic jaundice, is characterized by the absence of bile pigments in the urine and by normal stool colour. The colour of the urine is normal because the bilirubin in the blood is unconjugated to glucouronic acid and therefore bound to blood albumin and insoluble in water. Thus the bilirubin is not filtered by the kidney. The colour of stools remains normal because much of the bilirubin in the blood is filtered normally by the liver and enters the intestine promptly by way of the biliary system. Hemolytic diseases in newborn infants may lead to serious brain damage (kernicterus) if the unconjugated bilirubin crosses into the brain stem and destroys vital nuclei. The exposure to blue light of infants at risk for kernicterus converts the bilirubin to harmless and colourless degradation products. Unconjugated hyperbilirubinemia also occurs in many newborn infants, especially if they are premature, when the bilirubin transport enzyme systems are not fully developed (physiologic jaundice of the newborn). This disorder is self-limited, may require occasional exposures to blue light, and usually disappears within the first two weeks of extrauterine life. In Gilbert's disease, there is a fairly common hereditary reduction in one hepatic transport

Effects on newborn infants

protein, ligandin, and one conjugating enzyme, glucuronyl transferase. This results in a harmless lifelong tendency to mild degrees of unconjugated jaundice, especially during periods of fasting or fatigue.

Hepatocellular jaundice. A characteristic in all types of hepatitis and cirrhosis and in congestive liver disease, hepatocellular jaundice is characterized by dark amber urine and normal or slightly paler than normal stools. In hepatocellular jaundice, because much of the bilirubin in the blood already has been conjugated by the endoplasmic reticulum of the hepatocyte, it is water-soluble and can be filtered by the kidney. Stools are usually normal because some bile pigment also manages to be excreted into the biliary tract and intestine.

Cholestatic jaundice. Cholestatic jaundice is also distinguished by amber-coloured urine, but the colour of the stools is likely to be very pale (clay-coloured) owing to the failure of bile pigments to pass into the intestine. Itching of the skin is commonly associated with this condition. Cholestasis occurs in many types of hepatitis, especially those caused by certain drugs, and in diseases that primarily damage small bile passages in the liver (intraheptic cholestasis). Cholestatic jaundice also occurs in patients with obstructive disorders of the biliary tract outside of the liver (extrahepatic cholestasis). It is often impossible to determine the level of obstruction by means of examination alone, and more sophisticated testing is required to locate the site of damage.

PANCREAS

Pancreatitis. Inflammation of the pancreas, or pancreatitis, is probably the most common disease of this organ. The disorder may be confined to either singular or repeated acute episodes, or it may become a chronic disease. There are many factors associated with the onset of pancreatitis, including direct injury, certain drugs, viral infections, heredity, hyperlipidemia (increased levels of blood fats), and congenital derangements of the ductal system. In Western society most cases are related either to alcoholism or to gallstones, especially when stones pass spontaneously into the ampulla of Vater. Although the immediate cause of acute pancreatitis is not always clear, it seems to involve one or more of the following factors: heavy stimulation of pancreatic acini; increased pressure within the duct because of partial obstruction (gallstones) or edema (alcohol); and damage to the fine ductal network in the gland, which allows the escape of activated, potent, and destructive digestive enzymes into the substance of the pancreas itself and into surrounding tissues. Overstimulation of mechanisms of secretory enzyme production in the acinar cell may also lead to the energizing of intracellular (lysosomal) enzyme systems, resulting in the conversion of proenzymes to active forms that begin to digest cellular organelles. The gland thus begins to self-destruct. Similar damage may appear in other body organs, such as the lungs, kidneys, and blood vessels, which receive these activated enzymes by way of the bloodstream. It is not clear how the proenzyme trypsinogen is converted to trypsin in the damaged acinar cell, but it is known that the activation of the other proenzymes proceeds from this conversion. The extent of acinar destruction appears to depend on the strength of the causative factors.

Factors in the onset of pancreatitis

Localized, severe abdominal and midback pain resulting from enzyme leakage, tissue damage, and nerve irritation is the most common symptom of acute pancreatitis. In severe cases, respiratory failure, shock, and even death may occur. The severity of the symptoms generally depends on the extent of the damage to the pancreas; the mortality rate approaches 50 percent in severe (hemorrhagic) pancreatitis but is less than 5 percent in milder forms. The diagnosis is confirmed by the detection of elevated levels of pancreatic enzymes (amylase and lipase) in the blood and, if islet cell function is disturbed by the inflammatory process, elevated blood glucose values. Ultrasonographic or computed tomographic scans of the upper abdomen usually reveal an enlarged and swollen pancreas. Sustained pain, often with fever, suggests the presence of a pseudocyst or abscess caused by localized areas of destruction and infections in the pancreas.

Mortality rate

Acute pancreatitis is treated primarily by supportive therapy, with replacement of fluid and salt and control of pain. In severe cases, washing necrotic material and active enzymes from the abdominal cavity during surgery may be beneficial. Following recovery from an acute attack, the prevention of further attacks should be the primary goal. Thus, the removal of gallstones, cessation of alcohol ingestion, lowering of blood fats through diet, and discontinuation of toxic drugs (glucocorticoids and thiazide diuretics, for example) can be helpful measures. In instances where repeated attacks of acute pancreatitis have resulted in strictures (scars) of the main pancreatic duct, surgical repair may prevent further attacks.

Chronic pancreatitis. Chronic pancreatitis rarely follows repeated acute attacks. It seems instead to be a separate disorder that results in mucus plugs and precipitation of calcium salts in the smaller pancreatic ducts. The progressive loss of acinar and islet cell function follows, presumably as a consequence of continuous inflammation resulting from the ductal blockage. Progressive calcification, which at times results in the formation of large stones in the major pancreatic ducts, has been attributed to diminished production of an acinar protein that normally holds calcium in solution. Alcoholism and certain hereditary factors account for almost all of the cases of chronic pancreatitis seen in Western countries. Chronic protein malnutrition is an important element in underdeveloped countries. Recurrent abdominal pain, diabetes, and intestinal malabsorption of dietary nutrients are the main symptoms of chronic pancreatitis. Weight loss and deficiencies of fat-soluble vitamins (A, D, E, and K) are common. Treatment includes abstinence from alcohol, management of diabetes with insulin, and ingestion of pancreatic enzyme supplements to control dietary malabsorption.

Symptoms

Cystic fibrosis of the pancreas. Cystic fibrosis is inherited, but it is not expressed unless both members of a pair of hemologous, or corresponding, chromosomes carry the trait. The major functional abnormality in persons with the disease appears to be the elaboration by mucous glands throughout the body of secretions containing greater than normal concentrations of protein and calcium. This imbalance leads to increased viscosity of the secretions and precipitation of mucus and organic constituents in gland ducts. The resulting plugging process in the pancreas almost invariably causes destruction and scarring of the acinar tissue, usually without damaging the islets of Langerhans. A similar process in the hepatic biliary system produces foci of fibrosis and bile duct proliferation, a singular form of cirrhosis. In cystic fibrosis, the resulting pancreatic insufficiency usually can be treated by the oral replacement of pancreatic enzymes.

Cancer. Carcinoma of the pancreas arises primarily from the ductal system. The incidence of carcinoma of the pancreas has increased slightly (somewhat more in men than in women) and now exceeds cancer of the stomach. No certain risk factors have been identified, although suggestions have been made that pancreatic cancer occurs at increased rates among diabetics and persons with chronic pancreatitis. Upper abdominal pain, often radiating to the back, and weight loss are the most common symptoms of pancreatic cancer. Obstructive jaundice is a frequent symptom when the head of the pancreas is involved. The diagnosis is readily made in most cases by computed tomographic examination, at times supplemented by biopsy. There is no effective treatment, and more than 90 percent of patients die within the first year after diagnosis. If the tumour mass is localized and has not invaded blood vessels and nerves surrounding the pancreas, it occasionally can be removed surgically. Jaundice and intestinal obstruction can be relieved temporarily by surgical bypass procedures. Radiation and chemotherapy have shown some promise as therapeutic agents if they are started promptly in the course of the disease and continued for long periods.

Dinosaurs

Dinosaur is the common name given to a group of reptiles, often very large, that first appeared at least 228 million years ago, during the Late Triassic Period, and thrived worldwide for more than 150 million years. Most died out by the end of the Cretaceous Period, but many lines of evidence now show that one lineage evolved into modern-day birds.

The name dinosaur comes from the Greek words *deinos* ("terrible" or "fearfully great") and *sauros* ("reptile" or "lizard"). The English anatomist Richard Owen proposed the formal term "Dinosauria" in 1842 to include three giant extinct animals (*Megalosaurus, Iguanodon,* and *Hylaeosaurus*) represented by large fossilized bones that had been unearthed at several locations in southern England during the early part of the 19th century. Owen recognized that these reptiles were far different from other known reptiles of the present and the past for three reasons: they were large yet obviously terrestrial, unlike the aquatic ichthyosaurs and plesiosaurs that were already known; they had five vertebrae in their hips, whereas most known reptiles have only two; and, rather than holding their limbs sprawled out to the side in the manner of lizards, dinosaurs held their limbs under the body in columnar fashion, like elephants and other large mammals.

Originally applied to just a handful of incomplete specimens, the category Dinosauria now encompasses more than 800 generic names and at least 1,000 species, with new names being added to the roster every year as the result of scientific explorations around the world. Not all of these names are valid taxa, however. A great many of them have been based on fragmentary or incomplete material that may actually have come from two or more different dinosaurs. In addition, bones have sometimes been misidentified as dinosaurian when they are not from dinosaurs at all. Nevertheless, dinosaurs are well documented by abundant fossil remains recovered from every continent on Earth, and the number of known dinosaurian taxa is estimated to be 10–25 percent of actual past diversity.

The extensive fossil record of genera and species is testimony that dinosaurs were diverse animals, with widely varying lifestyles and adaptations. Their remains are found in sedimentary rock layers (strata) dating to the Late Triassic Period (230 million to 208 million years ago). The abundance of their fossilized bones is substantive proof that dinosaurs were the dominant form of terrestrial animal life during the Mesozoic Era (245 million to 66.4 million years ago). It is likely that the known remains represent a very small fraction (probably less than 0.0001 percent) of all the individual dinosaurs that once lived.

This article is divided into the following sections:

The search for dinosaurs

THE FIRST FINDS

Before Richard Owen introduced the term "Dinosauria" in 1842, there was no concept of anything even like a dinosaur. Large fossilized bones quite probably had been observed long before that time, but there is little record—and no existing specimens—of such findings much before 1818. In any case, people could not have been expected to understand what dinosaurs were even if they found their remains. For example, some classical scholars now conclude that the Greco-Roman legends of griffins from the 7th century BC were inspired by discoveries of protoceratopsian dinosaurs in the Altai region of Mongolia. In 1676 Robert Plot of the University of Oxford included, in a work of natural history, a drawing of what was apparently the knee-end of the thigh bone of a dinosaur, which he thought might have come from an elephant taken to Britain in Roman times. Fossil bones of what were undoubtedly dinosaurs were discovered in New Jersey in the late 1700s and were probably discussed at the meetings of the American Philosophical Society in Philadelphia. Soon thereafter, Lewis and Clark's expedition encountered dinosaur fossils in the western United States.

Initial explanations

The earliest verifiable published record of dinosaur remains that still exists is a note in the 1820 *American Journal of Science and Arts* by Nathan Smith. The bones described had been found in 1818 by Solomon Ellsworth, Jr., while he was digging a well at his homestead in Windsor, Connecticut. At the time, the bones were thought to be human, but much later they were identified as *Anchisaurus.* Even earlier (1800), large birdlike footprints had been noticed on sandstone slabs in Massachusetts. Pliny Moody, who discovered these tracks, attributed them to "Noah's raven," and Edward Hitchcock of Amherst College, who began collecting them in 1835, considered them to be those of some giant extinct bird. The tracks are now recognized as having been made by several different kinds of dinosaurs, and such tracks are still commonplace in the Connecticut River Valley today.

Better known are the finds in southern England during the early 1820s by William Buckland (a clergyman) and Gideon Mantell (a physician), who described *Megalosaurus* and *Iguanodon,* respectively. In 1824 Buckland

published a description of *Megalosaurus,* fossils of which consisted mainly of a lower jawbone with a few teeth. The following year Mantell published his "Notice on the *Iguanodon,* a Newly Discovered Fossil Reptile, from the Sandstone of Tilgate Forest, in Sussex," on the basis of several teeth and some leg bones. Both men collected fossils as an avocation and are credited with the earliest published announcements in England of what later would be recognized as dinosaurs. In both cases their finds were too fragmentary to permit a clear image of either animal. In 1834 a partial skeleton was found near Brighton that corresponded with Mantell's fragments from Tilgate Forest. It became known as the Maidstone *Iguanodon,* after the village where it was discovered. The Maidstone skeleton provided the first glimpse of what these creatures might have looked like.

Two years before the Maidstone *Iguanodon* came to light, a different kind of skeleton was found in the Weald of southern England. It was described and named *Hylaeosaurus* by Mantell in 1832 and later proved to be one of the armoured dinosaurs. Soon others began finding fossil bones in Europe. Owen identified two additional dinosaurs, albeit from fragmentary evidence: *Cladeiodon,* which was based on a single large tooth, and *Cetiosaurus,* which he named from an incomplete skeleton composed of very large bones. Having carefully studied most of these fossil specimens, Owen recognized that all of these bones represented a group of large reptiles that were unlike any living varieties. In a report to the British Association for the Advancement of Science in 1841, he described these animals, and the word "Dinosauria" was first published in the association's proceedings in 1842.

RECONSTRUCTION AND CLASSIFICATION

During the decades that followed Owen's announcement, many other kinds of dinosaurs were discovered and named in England and Europe: *Massospondylus* in 1854, *Scelidosaurus* in 1859, *Bothriospondylus* in 1875, and *Omosaurus* in 1877. Popular fascination with the giant reptiles grew, reaching a peak in the 1850s with the first attempts to reconstruct the three animals on which Owen based Dinosauria—*Iguanodon, Megalosaurus,* and *Hylaeosaurus*—for the first world exposition, the Great Exhibition of 1851 in London's Crystal Palace. A sculptor under Owen's direction (Waterhouse Hawkins) created life-size models of these two genera, and in 1854 they were displayed together with models of other extinct and living reptiles, such as plesiosaurs, ichthyosaurs, and crocodiles.

By the 1850s it had become evident that the reptile fauna of the Mesozoic Era was far more diverse and complex than it is today. The first important attempt to establish an informative classification of the dinosaurs was made by the English biologist T.H. Huxley as early as 1868. Because he observed that these animals had legs similar to birds as well as other birdlike features, he established a new order called Ornithoscelida. He divided the order into two suborders. Dinosauria was the first and included the iguanodonts, the large carnivores (or megalosaurids), and the armoured forms (including *Scelidosaurus*). Compsognatha was the second order, named for the very small birdlike carnivore *Compsognathus.*

Two types of dinosaurs

Huxley's classification was replaced by a radically new scheme proposed in 1887 by his fellow Englishman H.G. Seeley, who noticed that all dinosaurs possessed one of two distinctive pelvic designs, one like that of birds and the other like that of reptiles. Accordingly, he divided the dinosaurs into the orders Ornithischia (having a birdlike pelvis) and Saurischia (having a reptilian pelvis). Ornithischia included four suborders: Ornithopoda (*Iguanodon* and similar herbivores), Stegosauria (plated forms), Ankylosauria (*Hylaeosaurus* and other armoured forms), and Ceratopsia (horned dinosaurs, just then being discovered in North America). Seeley's second order, the Saurischia, included all the carnivorous dinosaurs, such as *Megalosaurus* and *Compsognathus,* as well as the giant herbivorous sauropods, including *Cetiosaurus* and several immense "brontosaur" types that were turning up in North America. In erecting Saurischia and Ornithischia, Seeley cast doubt on the idea that Dinosauria was a natural grouping of these animals. This uncertainty persisted for a century thereafter, but it is now understood that the two groups share unique features that indeed make the Dinosauria a natural group.

Figure 1: *Iguanodon* skeleton reconstructed with an upright posture by Louis Dollo in the 19th century.

A herd of *Iguanodon*

In 1878 a spectacular discovery was made in the town of Bernissart, Belgium, where several dozen complete articulated skeletons of *Iguanodon* were accidentally uncovered in a coal mine during the course of mining operations. Under the direction of the Royal Institute of Natural Science of Belgium, thousands of bones were retrieved and carefully restored over a period of many years. The first skeleton was placed on exhibit in 1883, and today the public can view an impressive herd of *Iguanodon.* The discovery of these multiple remains gave the first hint that at least some dinosaurs may have traveled in groups and showed clearly that some dinosaurs were bipedal (walking on two legs). The supervisor of this extraordinary project was Louis Dollo, a zoologist who was to spend most of his life studying *Iguanodon,* working out its structure, and speculating on its living habits (Figure 1).

AMERICAN HUNTING EXPEDITIONS

England and Europe produced most of the early discoveries and students of dinosaurs, but North America soon began to contribute a large share of both. One leading student of fossils was Joseph Leidy of the Academy of Natural Sciences in Philadelphia, who named some of the earliest dinosaurs found in America, including *Palaeoscincus, Trachodon, Troodon,* and *Deinodon.* Unfortunately, some names given by Leidy are no longer used, because they were based on such fragmentary and undiagnostic material. Leidy is perhaps best known for his study and description of the first dinosaur skeleton to be recognized in North America, that of a duckbill, or hadrosaur, found at Haddonfield, New Jersey, in 1858, which he named *Hadrosaurus foulkii.* Leidy's inference that this animal was probably amphibious influenced views of dinosaur life for the next century.

Two Americans whose work during the second half of the 19th century had worldwide impact on the science of paleontology in general, and the growing knowledge of dinosaurs in particular, were O.C. Marsh of Yale College and E.D. Cope of Haverford College, the University of Pennsylvania, and the Academy of Natural Sciences in Philadelphia. All previous dinosaur remains had been discovered by accident in well-populated regions with temperate, moist climates, but Cope and Marsh astutely focused their attention on the wide arid expanses of bare exposed rock in western North America. In their intense quest to find and name new di-

nosaurs, these scientific pioneers became fierce and unfriendly rivals.

Marsh's field parties explored widely, exploiting dozens of now famous areas, among them Yale's sites at Morrison and Canon City, Colorado, and, most important, Como Bluff in southeastern Wyoming. The discovery of Como Bluff in 1877 was a momentous event in the history of paleontology that generated a burst of exploration and study as well as widespread public enthusiasm for dinosaurs. Como Bluff brought to light one of the greatest assemblages of dinosaurs, both small and gigantic, ever found. For decades the site went on producing the first known specimens of Late Jurassic Period (163 million to 144 million years ago) dinosaurs such as *Stegosaurus, Camptosaurus, Camarasaurus, Laosaurus, Coelurus,* and others. From the Morrison site came the original specimens of *Allosaurus, Diplodocus, Atlantosaurus,* and *Brontosaurus* (later renamed *Apatosaurus*). Canon City provided bones of a host of dinosaurs, including *Stegosaurus, Brachiosaurus, Allosaurus,* and *Camptosaurus.* Marsh's specimens now form the core of the Mesozoic collections at the National Museum of Natural History of the Smithsonian Institution and the Peabody Museum of Natural History at Yale University.

Cope's dinosaur explorations ranged as far as, or farther than, Marsh's, and his interests encompassed a wider variety of fossils. Owing to a number of circumstances, however, Cope's dinosaur discoveries were fewer and his collections far less complete than those of Marsh. Perhaps his most notable achievement was finding and proposing the names for *Coelophysis* and *Monoclonius.* Cope's dinosaur explorations began in the eastern badlands of Montana, where he discovered *Monoclonius* in the Judith River Formation of the Cretaceous Period (97.5 million to 66.4 million years ago). Accompanying him there was a talented young assistant, Charles H. Sternberg. Later Sternberg and his three sons went on to recover countless dinosaur skeletons from the Oldman and Edmonton formations of the Late Cretaceous along the Red Deer River of Alberta, Canada.

DINOSAUR ANCESTORS

During the early decades of dinosaur discoveries, little thought was given to their evolutionary ancestry. Not only were the few specimens known unlike any living animal, but they were so different from any other reptiles that it was difficult to discern much about their relationships. Early on it was recognized that, as a group, dinosaurs appear to be most closely allied to crocodilians, though T.H. Huxley had proposed in the 1860s that dinosaurs and birds must have had a very close common ancestor in the distant past. Three anatomic features—socketed teeth, a skull with two large holes (diapsid), and another hole in the lower jaw—are present in both crocodiles and dinosaurs. The earliest crocodilians occurred nearly simultaneously with the first known dinosaurs, so neither could have given rise to the other. It was long thought that the most likely ancestry of dinosaurs could be found within a poorly understood group of Triassic reptiles termed thecodontians ("socket-toothed reptiles"). Today it is recognized that "thecodontian" is simply a name for the basal, or most primitive, members of the archosaurs ("ruling reptiles"), a group that is distinguished by the three anatomic features mentioned above and that includes dinosaurs, pterosaurs (flying reptiles), crocodiles, and their extinct relatives. An early candidate for the ancestor of dinosaurs was a small basal archosaur from the Early Triassic Period (245 million to 240 million years ago) of South Africa called *Euparkeria.* New discoveries suggest creatures that are even more dinosaur-like from the Middle Triassic (240 million to 230 million years ago) and from an early portion of the Late Triassic (230 million to 208 million years ago) of South America; these include *Lagerpeton, Lagosuchus, Pseudolagosuchus,* and *Lewisuchus.* Other South American forms such as *Eoraptor* and *Herrerasaurus* are particularly dinosaurian in appearance and are sometimes considered dinosaurs.

An uncertain origin

The earliest appearance of "true dinosaurs" is almost impossible to pinpoint, since it can never be known with certainty whether the very first (or last) specimen of any kind of organism has been found. The succession of deposits containing fossils is discontinuous and contains many gaps; even within these deposits, the fossil record of dinosaurs and other creatures contained within is far from complete. Further complicating matters is that evolution from ancestral to descendant form is usually a stepwise process. Consequently, as more and more gaps are filled between the first dinosaurs and other archosaurs, the number of features distinguishing them becomes smaller and smaller. Currently, paleontologists define dinosaurs as *Triceratops* (representing Ornithischia), birds (the most recent representatives of the Saurischia), and all the descendants of their most recent common ancestor. Compared with most of their contemporaries, dinosaurs had an improved stance and posture with a resulting improved gait and, in several independent lineages, an overall increase in size. They also were more efficient at gathering food and processing it and apparently had higher metabolic rates and cardiovascular nourishment. All these trends, individually or in concert, probably contributed to the collective success of dinosaurs, which resulted in their dominance among the terrestrial animals of the Mesozoic

MODERN STUDIES

During the first century or more of dinosaur awareness, workers in the field more or less concentrated on the search for new specimens and new types. Their discoveries then required detailed description and analysis, followed by comparisons with other known dinosaurs in order to classify the new finds and develop hypotheses about evolutionary relationships. These pursuits continue, but newer methods of exploration and analysis have been adopted. Emphasis has shifted from purely descriptive procedures to analyses of relationships by using the methods of cladistics, which dispenses with the traditional taxonomic hierarchy in favour of "phylogenetic trees" that are more explicit about evolutionary relationships. Phylogenetic analyses also help us to understand how certain features evolved in groups of dinosaurs and give us insight into their possible functions.

Reconstructing dinosaurs

Functional anatomic studies extensively use analogous traits of present-day animals that, along with both mechanical and theoretical models, make it possible to visualize certain aspects of extinct animals. For example, estimates of normal walking and maximum running speeds can be calculated on the basis of the analysis of trackways, which can then be combined with biomechanical examination of the legs and joints and reconstruction of limb musculature. Similar methods have been applied to jaw mechanisms and tooth wear patterns to obtain a better understanding of feeding habits and capabilities.

The soft parts of dinosaurs are only imperfectly known. Original colours and patterns cannot be known, but skin textures have occasionally been preserved. Most show a knobby or pebbly surface rather than a scaly texture as in most living reptiles. Impressions of internal organs are rarely preserved, but, increasingly, records of filaments and even feathers have been found on some dinosaurs. Gastroliths ("stomach stones") used for processing food in the gizzard have been recovered from a variety of dinosaurs.

EXTINCTION

A misconception commonly portrayed in popular books and media is that all the dinosaurs died out at the same time—and apparently quite suddenly—at the end of the Cretaceous Period 66.4 million years ago. This is not entirely correct, and not only because birds are a living branch of dinosaurian lineage. The best records, which are almost exclusively from North America, show that dinosaurs were already in decline during the latest portion of the Cretaceous. The causes of this decline, as well as the fortunes of other groups at the time, are complex and difficult to attribute to a single source. In order to understand extinction, it is necessary to understand the basic fossil record of dinosaurs.

Faunal changes. During the 180 million years or so of the Mesozoic Era (245 million to 66.4 million years ago) from which dinosaurs are known, there were constant changes in dinosaur communities. Different species

evolved rapidly and were quickly replaced by others throughout the Mesozoic; it is rare that any particular type of dinosaur survived from one geologic formation into the next, but the overall picture is quite clear: throughout Mesozoic time there was a continuous dying out and renewal of dinosaurian life.

Extinction processes

It is important to note that extinction is a normal, universal occurrence. Mass extinctions often come to mind when the term extinction is mentioned, but the normal background extinctions that occur throughout geologic time probably account for most losses of biodiversity. Just as new species constantly split from existing ones, existing species are constantly becoming extinct. The speciation rate of a group must, on balance, exceed the extinction rate in the long run, or that group will become extinct. The history of animal and plant life is replete with successions as early forms are replaced by new and often more advanced forms. In most instances the layered (stratigraphic) nature of the fossil record gives too little information to show whether the old forms were actually displaced by the new successors (from the effects of competition, predation, or other ecological processes) or if the new kinds simply expanded into the declining population's ecological niches.

Because the fossil record is episodic rather than continuous, it is very useful for asking many kinds of questions, but it is not possible to say precisely how long most dinosaur species or genera actually existed. Moreover, because the knowledge of the various dinosaur groups is somewhat incomplete, the duration of any particular dinosaur can be gauged only approximately—usually by stratigraphic boundaries and presumed "first" and "last" occurrences. The latter often coincide with geologic age boundaries; in fact, the absence of particular life-forms has historically defined most geologic boundaries ever since the geologic record was first compiled and analyzed in the late 18th century. The "moments" of apparently high extinction levels among dinosaurs were near the ends of two stages of the Triassic (about 225 million and 208 million years ago), perhaps at the end of the Jurassic (144 million years ago), and of course at the end of the Cretaceous (66.4 million years ago). Undoubtedly, there were lesser extinction peaks at other times in between, but there are poor terrestrial records for most of the world in the Middle Triassic, Middle Jurassic, and mid-Cretaceous.

The K–T boundary event. It was not only the dinosaurs that disappeared 66.4 million years ago at the Cretaceous–Tertiary, or K–T, boundary. Many other organisms became extinct or were greatly reduced in abundance and diversity, and the extinctions were quite different between, and even among, marine and terrestrial organisms. Land plants did not respond in the same way as land animals, and not all marine organisms showed the same patterns of extinction. Some groups died out well before the K–T boundary, including flying reptiles (pterosaurs) and sea reptiles (plesiosaurs, mosasaurs, and ichthyosaurs). Strangely, turtles, crocodilians, lizards, and snakes were either not affected or affected only slightly. Effects on amphibians and mammals were mild. These patterns seem odd, considering how environmentally sensitive and habitat-restricted many of these groups are today.

Whatever factors caused it, there was undeniably a major, worldwide biotic change near the end of the Cretaceous. But the extermination of the dinosaurs is the best-known change by far, and it has been a puzzle to paleontologists, geologists, and biologists for two centuries. Many hypotheses have been offered over the years to explain dinosaur extinction, but only a few have received serious consideration. Proposed causes have included everything from disease to heat waves and resulting sterility, freezing cold spells, the rise of egg-eating mammals, and X rays from a nearby exploding supernova. Since the early 1980s, attention has focused on the so-called asteroid theory put forward by the American geologist Walter Alvarez, his father, physicist Luis Alvarez, and their coworkers. This theory is consistent with the timing and magnitude of some extinctions, especially in the oceans, but it does not fully explain the patterns on land and does not eliminate the possibility that other factors were at work on land as well as in the seas.

One important question is whether the extinctions were simultaneous and instantaneous or whether they were nonsynchronous and spread over a long time. The precision with which geologic time can be measured leaves much to be desired no matter what means are used (radiometric, paleomagnetic, or the more traditional measuring of fossil content of stratigraphic layers). Only rarely does an "instantaneous" event leave a worldwide—or even regional—signature in the geologic record in the way that a volcanic eruption does locally. Attempts to pinpoint the K–T boundary event, even by using the best radiometric dating techniques, result in a margin of error on the order of 50,000 years. Consequently, the actual time involved in this, or any of the preceding or subsequent extinctions, has remained undetermined.

The asteroid theory. The discovery of an abnormally high concentration of the rare metal iridium at, or very close to, the K–T boundary provides what has been recognized as one of those rare instantaneous geologic time markers that seem to be worldwide. This iridium anomaly, or spike, was first found by Walter Alvarez in the Cretaceous–Tertiary stratigraphic sequence at Gubbio, Italy, in the 1970s. The spike has subsequently been detected at hundreds of localities in Denmark and elsewhere, both in rock outcrops on land and in core samples drilled from ocean floors.

Because the levels of iridium are higher in meteorites than on the Earth, the Gubbio anomaly is thought to have an extraterrestrial explanation. If this is true, such extraterrestrial signatures will have a growing influence on the precision with which geologic time boundaries can be specified. The level of iridium in meteorites has been accepted as representing the average level throughout the solar system and, by extension, the universe. Accordingly, the iridium concentration at the K–T boundary is widely attributed to a collision between the Earth and a huge meteor or asteroid. The impact site (called an astrobleme) of such a collision may have been identified in the Chicxulub crater in Mexico's Yucatán Peninsula.

The asteroid theory is widely accepted as the most probable explanation of the K–T iridium anomaly, but it does not appear to account for all the paleontological data. An impact explosion of this kind would have ejected an enormous volume of terrestrial and asteroid material into the atmosphere, producing a cloud of dust and solid particles that would have encircled the Earth and blocked out sunlight for many months, possibly years. The loss of sunlight could have eliminated photosynthesis and resulted in the death of plants and the subsequent extinction of herbivores, their predators, and scavengers.

Non-asteroid theories

The K–T mass extinctions, however, do not seem to be fully explained by this hypothesis. The stratigraphic record is most complete for extinctions of marine life—foraminifera, ammonites, coccolithophores, and the like. These apparently died out suddenly and simultaneously, and their extinction accords best with the asteroid theory. The fossil evidence of land dwellers, however, suggests a gradual rather than a sudden decline in dinosaurian diversity (and possibly abundance). Alterations in terrestrial life seem to be best accounted for by environmental factors, such as the consequences of seafloor spreading and continental drift, resulting in continental fragmentation, climatic deterioration, increased seasonality, and perhaps changes in the distributions and compositions of terrestrial communities. But one phenomenon does not preclude another. It is entirely possible that a culmination of ordinary biological changes and some catastrophic events, including increased volcanic activity, took place around the end of the Cretaceous.

Dinosaur descendants. Contrary to the commonly held belief that the dinosaurs left no descendants, the seven specimens of *Archaeopteryx* (the earliest bird known) provide compelling evidence that birds (class Aves) evolved from small theropod dinosaurs. Following the principles of genealogy that are applied to humans as much as to other organisms, organisms are classified at a higher level within the groups from which they evolved. *Archaeopteryx* is therefore classified as both a dinosaur and a bird, just as humans are both primates and mammals.

The specimens of *Archaeopteryx* contain particular anatomic features that also are exclusively present in certain theropods (*Oviraptor, Velociraptor, Deinonychus,* and *Troodon,* among others). These animals share long arms and hands, a somewhat shorter, stiffened tail, a similar pelvis, and an unusual wrist joint in which the hand is allowed to flex sideways instead of up and down. This wrist motion is virtually identical to the motion used by birds (and bats) in flight, though in these small dinosaurs its initial primary function was probably in catching prey.

The origin of feathers

Beginning in the 1990s, several specimens of small theropod dinosaurs from the Early Cretaceous of Liaoning province, China, were unearthed. These fossils are remarkably well preserved, and because they include impressions of featherlike, filamentous structures that covered the body, they have shed much light on the relationship between birds and Mesozoic dinosaurs. Such structures on the skin of *Sinosauropteryx* are similar to the barbs of feathers, which suggests that feathers evolved from a much simpler structure that probably functioned as an insulator. True feathers of several types, including contour and body feathers, have been found in the 125-million-year-old feathered oviraptorid *Caudipteryx* and the apparently related *Protarchaeopteryx.* Because these animals were not birds and did not fly, it is now evident that true feathers neither evolved first in birds nor developed for the purpose of flight. Instead, feathers may have evolved for insulation, display, camouflage, species recognition, or some combination of these functions and only later became adapted for flight. In the case of *Caudipteryx,* for example, it has been established that these animals not only sat on nests but probably protected the eggs with their feathers.

Because representatives of living bird groups have long been known among the fossil species from the Paleocene and Eocene epochs (66.4 million to 36.6 million years ago), it has seemed evident that birds must have existed during the Cretaceous. Knowledge of these, based on fragments of fossil bone, has slowly come to light, and there is now a fairly definite record from Cretaceous rock strata of other ancestral birds related to the living groups of loons, grebes, flamingos, cranes, parrots, and shorebirds—and thus indication of early avian diversity. Therefore, it is clear that birds did not go through a "bottleneck" of extinction at the end of the Cretaceous that separated the archaic groups from the extant groups. Rather, the living groups were mostly present by the latest Cretaceous, and by this time the archaic groups seem to have died out.

Natural history

HABITATS

Dinosaurs lived in many kinds of terrestrial environments, and although some remains, such as footprints, indicate where dinosaurs actually lived, their bones tell us only where they died (assuming that they have not been scattered or washed far from their place of death). Not all environments are equally well preserved in the fossil record. Upland environments, forests, and plains tend to experience erosion or decomposition of organic remains, so remains from these environments are rarely preserved in the geologic record. As a result, most dinosaur fossils are known from lowland environments, usually floodplains, deltas, lake beds, stream bottoms, and even some marine environments, where their bones apparently washed in after death. Much about the environments dinosaurs lived in can be learned from studying the pollen and plant remains preserved with them and from geochemical isotopes that indicate temperature and precipitation levels. These climates, although free from the extensive ice caps of today and generally more equable, suffered extreme monsoon seasons and made much of the globe arid.

FOOD AND FEEDING

The plant eaters. From the Triassic through the Jurassic and into the Cretaceous, the Earth's vegetation changed slowly but fundamentally from forests rich in gymnosperms (cycadeoids, cycads, and conifers) to angiosperm-dominated forests of palmlike trees and magnolia-like hardwoods. Although conifers continued to flourish at high latitudes, palms were increasingly confined to subtropical and tropical regions. These forms of plant life, the vast majority of them low in calories and proteins and made largely of hard-to-digest cellulose, became the foods of changing dinosaur communities. Accordingly, certain groups of dinosaurs, such as the ornithopods, included a succession of types that were increasingly adapted for efficient food processing. At the peak of the ornithopod lineage, the hadrosaurs (duck-billed dinosaurs of the Late Cretaceous) featured large dental batteries in both the upper and lower jaws, which consisted of many tightly compressed teeth that formed a long crushing or grinding surface. The preferred food of the duckbills cannot be certified, but at least one specimen found in Wyoming offers an intriguing clue: fossil plant remains in the stomach region have been identified as pine needles.

The hadrosaurs' Late Cretaceous contemporaries, the ceratopsians (horned dinosaurs), had similar dental batteries that consisted of dozens of teeth. In this group the upper and lower batteries came together and acted as serrated shearing blades rather than crushing or grinding surfaces. Ordinarily, slicing teeth are found only in flesh-eating animals, but the bulky bodies and the unclawed, hooflike feet of dinosaurs such as *Triceratops* clearly are those of plant eaters.

The giant sauropods such as *Diplodocus* and *Apatosaurus* must have required large quantities of plant food, but there is no direct evidence as to the particular plants they preferred. Because angiosperms rich in calories and proteins did not exist during most of the Mesozoic Era, it must be assumed that these sauropods fed on the abundant conifers and palm trees. Such a cellulose-heavy diet would have required an unusual bacterial population in the intestines to break down the fibre. A digestive tract with one or more crop chambers containing stones might have aided in the food-pulverizing process, but such gastroliths, or "stomach-stones," are only rarely found in association with dinosaur skeletons. (A *Seismosaurus* specimen found with several hundred such stones is an important exception.)

The food preference of herbivorous dinosaurs can be inferred to some extent from their general body plan and from their teeth. It is probable, for example, that low-built animals such as the ankylosaurs, stegosaurs, and ceratopsians fed on low shrubbery. The tall ornithopods, especially the duckbills, and the long-necked sauropods probably browsed on high branches and treetops. No dinosaurs could have fed on grasses (family Poaceae), as these plants had not yet evolved.

The flesh eaters. The flesh-eating dinosaurs came in all shapes and sizes and account for about 40 percent of the diversity of Mesozoic dinosaurs. They must have eaten anything they could catch, because predation is a highly opportunistic lifestyle. In several instances the prey victim of a particular carnivore has been established beyond much doubt. Remains were found of the small predator *Compsognathus* containing a tiny skeleton of the lizard *Bavarisaurus* in its stomach region. In Mongolia two different dinosaur skeletons were found together, a nearly adult-size *Protoceratops* in the clutches of its predator *Velociraptor.* Two of the many skeletons of *Coelophysis* discovered at Ghost Ranch in New Mexico, U.S., contained bones of several half-grown *Coelophysis,* apparently an early Mesozoic example of cannibalism. Fossilized feces (coprolites) from a large tyrannosaur contained crushed bone of another dinosaur. Skeletons of *Deinonychus* unearthed in Montana, U.S., were mixed with fragmentary bones of a much larger victim, the herbivore *Tenontosaurus.* This last example is significant because the multiple remains of the predator *Deinonychus,* associated with the bones of a single large prey animal, *Tenontosaurus,* strongly suggest that *Deinonychus* hunted in packs.

HERDING BEHAVIOUR

It should not come as a surprise that *Deinonychus* was a social animal, because many animals today are gregarious and form groups. Fossil evidence documents similar herding behaviour in a variety of dinosaurs. The mass assemblage in Bernissart, Belgium, for example, held at least

three groups of *Iguanodon.* Group association and activity is also indicated by the dozens of *Coelophysis* skeletons of all ages recovered in New Mexico, U.S. The many specimens of *Allosaurus* at the Cleveland-Lloyd Quarry in Utah, U.S., may denote a herd of animals attracted to the site for the common purpose of scavenging. In the last two decades, several assemblages of ceratopsians and duckbills containing thousands of individuals have been found. Even *Tyrannosaurus rex* is now known from sites where a group has been preserved together.

Dinosaur footprints

These rare occurrences of multiple skeletal remains have repeatedly been reinforced by dinosaur footprints as evidence of herding. Trackways were first noted by Roland T. Bird in the early 1940s along the Paluxy River bed in central Texas, U.S. (Figure 2). One set of numerous wash-basin-size depressions proved to be a series of giant sauropod footsteps preserved in limestone of the Early Cretaceous Period (144 million to 97.5 million years ago). Because the tracks are nearly parallel and all progress in the same direction, Bird concluded that "all were headed toward a common objective" and suggested that the sauropod trackmakers "passed in a single herd." Large trackway sites also exist in the eastern and western United States, Canada, Australia, England, Argentina, South Africa, and China, among other places. These sites, dating from the Late Triassic Period (230 million to 208 million years ago) to the latest Cretaceous (66.4 million years ago), document herding as common behaviour among a variety of dinosaur types.

Some dinosaur trackways record hundreds, perhaps even thousands, of animals, possibly indicating mass migrations. The existence of so many trackways suggests the presence of great populations of sauropods, prosauropods, ornithopods, and probably most other kinds of dinosaurs. The majority must have been herbivores, and many of them were huge, weighing several tons or more. The impact of such large herds on the plant life of the time must have been great, suggesting constant migration in search of food.

Nesting sites discovered in the late 20th century also establish herding among dinosaurs. Nests and eggs numbering from dozens to thousands are preserved at sites that were possibly used for thousands of years by the same evolving populations of dinosaurs.

GROWTH AND LIFE SPAN

Much attention has been devoted to dinosaurs as living animals—moving, eating, growing, reproducing biological machines. But how fast did they grow? How long did they live? How did they reproduce? The evidence concerning growth and life expectancy is sparse but growing. In the 1990s histological studies of fossilized bone by Armand de Ricqlès in Paris and R.E.H. Reid in Ireland showed that dinosaur skeletons grew quite rapidly. The time required for full growth has not been quantified for most dinosaurs, but de Ricqlès and his colleagues have shown that duckbills (hadrosaurs) such as *Hypacrosaurus* and *Maiasaura* reached adult size in seven or eight years and that the giant sauropods reached nearly full size in as little as 12 years. How long dinosaurs lived after reaching adult size is difficult to determine, but it is thought that the majority of known skeletons are not fully grown, because their bone ends and arches are very often not fused; in mature individuals these features would be fused.

REPRODUCTION

The idea that dinosaurs, like most living reptiles and birds, built nests and laid eggs had been widely debated even before the 1920s, when a team of scientists led by Roy Chapman Andrews from the American Museum of Natural History, New York, made an expedition to Mongolia. Their discovery of dinosaur eggs in the Gobi Desert proved conclusively that at least one kind of dinosaur had been an egg layer and nest builder. These eggs were at first attributed to *Protoceratops,* but they are now known to have been those of *Oviraptor* (Figure 3). In 1978 John R. Horner and his field crews from Princeton University discovered dinosaur nests in western Montana. A few other finds, mostly of eggshell fragments from a number of sites, established oviparity as the only known mode of reproduction. In recent years an increasing number of dinosaur eggshells have been found and identified with the dinosaurs that laid them, and embryos have been found inside some eggs.

The almost complete absence of juvenile dinosaur remains was puzzling until the 1980s. Horner, having moved to Montana State University, demonstrated that most paleontologists simply had not been exploring the right territory. After a series of intensive searches for the remains of immature dinosaurs, he succeeded beyond all expectations. The first such bones were unearthed near Choteau, Montana, and thereafter Horner and his crews discovered hundreds of nests, eggs, and newly hatched dinosaurs (mostly duckbills). Egg Mountain, as the area was named, produced some of the most important clues to dinosauri-

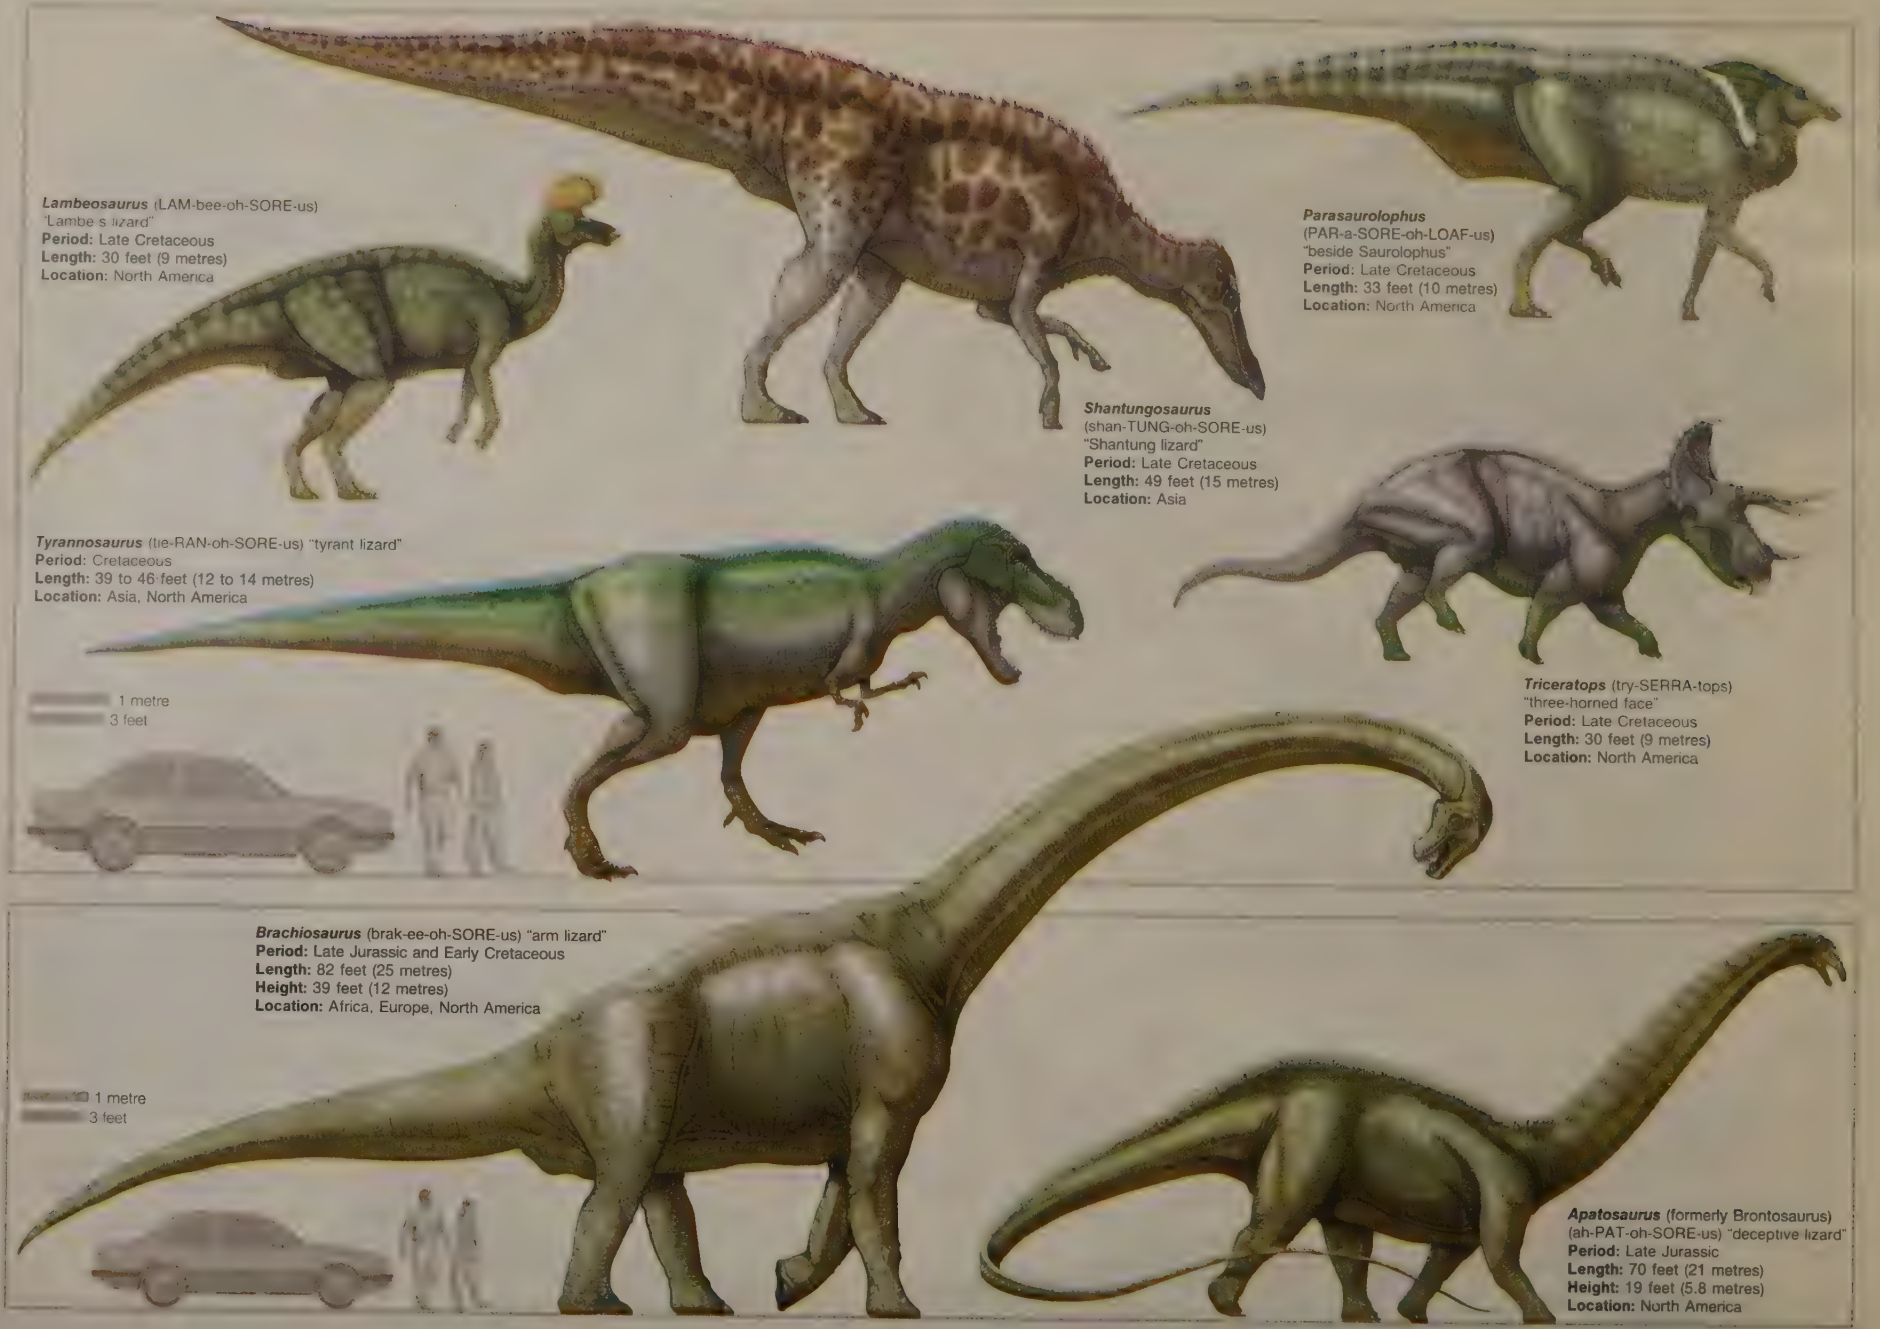
Euoplocephalus (YOU-op-loh-SEF-ah-lus)
"well-armoured head"
Period: Late Cretaceous
Length: 23 feet (7 metres)
Location: North America
Allosaurus (AL-oh-SORE-us) "other lizard"
Period: Late Jurassic
Length: 25 to 35 feet (7.5 to 10.5 metres)
Location: Africa, Australia, North America
Stegosaurus (STEG-oh-SORE-us)
"roof lizard"
Period: Late Jurassic
Length: 30 feet (9 metres)
Location: North America
Iguanodon (ig-WHA-noh-don) "iguana tooth"
Period: Late Jurassic and Early Cretaceous
Length: 30 feet (9 metres)
Location: Africa, Asia, Australia, Europe, North America



Lambeosaurus (LAM-bee-oh-SORE-us)
"Lambe s lizard"
Period: Late Cretaceous
Length: 30 feet (9 metres)
Location: North America

Parasaurolophus
(PAR-a-SORE-oh-LOAF-us)
"beside Saurolophus"
Period: Late Cretaceous
Length: 33 feet (10 metres)
Location: North America

Shantungosaurus
(shan-TUNG-oh-SORE-us)
"Shantung lizard"
Period: Late Cretaceous
Length: 49 feet (15 metres)
Location: Asia

Tyrannosaurus (tie-RAN-oh-SORE-us) "tyrant lizard"
Period: Cretaceous
Length: 39 to 46 feet (12 to 14 metres)
Location: Asia, North America

1 metre
3 feet

Triceratops (try-SERRA-tops)
"three-horned face"
Period: Late Cretaceous
Length: 30 feet (9 metres)
Location: North America

Brachiosaurus (brak-ee-oh-SORE-us) "arm lizard"
Period: Late Jurassic and Early Cretaceous
Length: 82 feet (25 metres)
Height: 39 feet (12 metres)
Location: Africa, Europe, North America

1 metre
3 feet

Apatosaurus (formerly Brontosaurus)
(ah-PAT-oh-SORE-us) "deceptive lizard"
Period: Late Jurassic
Length: 70 feet (21 metres)
Height: 19 feet (5.8 metres)
Location: North America

an habits yet found. For example, the sites show that a number of different dinosaur species made annual treks to this same nesting ground (though perhaps not all at the same time). Because of the succession of similar nests and eggs lying one on top of the other, it is thought that particular species returned to the same site year after year to lay their clutches. As Horner concluded, "site fidelity" was an instinctive part of dinosaurian reproductive strategy. This was confirmed more recently with the discovery of sauropod nests and eggs spread over many square kilometres in Patagonia, Argentina.

BODY TEMPERATURE

Beyond eating, digestion, assimilation, reproduction, and nesting, many other processes and activities went into making the dinosaur a successful biological machine. Breathing, fluid balance, temperature regulation, and other such capabilities are also required. Dinosaurian body temperature regulation, or lack thereof, has been a hotly debated topic among students of dinosaur biology. Because it is obviously not possible to take an extinct dinosaur's temperature, all aspects of their metabolism and thermophysiology can be assessed only indirectly.

Ectothermy and endothermy. All animals thermoregulate. The internal environment of the body is under the influence of both external and internal conditions. Land animals thermoregulate in several ways. They do so behaviorally, by moving to a colder or warmer place, by exercising to generate body heat, or by panting or sweating to lose it. They also thermoregulate physiologically, by activating internal metabolic processes that warm or cool the blood. But these efforts have limits, and, as a result, external temperatures and climatic conditions are among the most important factors controlling the geographic distribution of animals.

Present-day metabolisms

Today's so-called warm-blooded animals are the mammals and birds; reptiles, amphibians, and most fishes are called cold-blooded. These two terms, however, are imprecise and misleading. Some "cold-blooded" lizards have higher normal body temperatures than do some mammals, for instance. Another pair of terms, "ectothermy" and "endothermy," describes whether most of an animal's heat is absorbed from the environment ("ecto-") or generated by internal processes ("endo-"). A third pair of terms, "poikilothermy" and "homeothermy," describes whether the body temperature tends to vary with that of the immediate environment or remains relatively constant.

Today's mammals and birds have a high metabolism and are considered endotherms, which produce body heat internally. They possess biological temperature sensors that control heat production and switch on heat-loss mechanisms such as perspiration. Today's reptiles and amphibians, on the other hand, are ectotherms that mostly gain heat energy from sunlight, a heated rock surface, or some other external source. The endothermic state is effective but metabolically expensive, as the body must produce heat continuously, which requires correspondingly high quantities of fuel in the form of food. On the other hand, endotherms can be more active and survive lower external temperatures. Ectotherms do not require as much fuel, but most cannot deal as well with cold surroundings.

From the time of the earliest discoveries in the 19th century, dinosaur remains were classified as reptilian because their anatomic features are typical of living reptiles such as turtles, crocodiles, and lizards. Because dinosaurs all have lower jaws constructed of several bones, a reptilian jaw joint, and a number of other nonmammalian, nonbirdlike characteristics, it was assumed that living dinosaurs were similar to living reptiles—scaly, cold-blooded, ectothermic egg layers (predominantly), not furry, warm-blooded livebearers. A chauvinistic attitude seems to prevail that the warm-bloodedness of mammals is better than the cold-blooded reptilian state, even though turtles, snakes, and other reptiles do very well regulating their body temperature in a different way. Moreover, both birds and mammals evolved from ectothermic, poikilothermic ancestors. At what point did metabolism heat up?

Clues to dinosaurian metabolism. The question of whether any extinct dinosaur was a true endotherm or homeotherm cannot be answered, but some interesting anatomic facts suggest these "warmer" possibilities. Probably the most direct evidence of dinosaurian physiology comes from bones themselves, particularly in regard to how they grew. The long bones (such as arm and leg bones) of most dinosaurs are composed almost exclusively of a well-vascularized type of bone matrix (fibro-lamellar) also found in most mammals and large birds. This type of bone tissue always indicates rapid growth, and it is very different from the more compact, poorly vascularized, parallel-fibred bone found in crocodiles and other reptiles and amphibians. It is generally thought that well-vascularized, rapidly growing bone can be sustained only by high metabolic rates that bring a continual source of nutrients and minerals to the growing tissues. It is difficult to explain these histological features in any other metabolic terms. On the other hand, most dinosaurs retain lines of arrested growth (LAGs) in most of their long bones. LAGs are found in other reptiles, amphibians, and fishes, and they often reflect a seasonal period during which metabolism slows, usually because of environmental stresses. This slowdown produces "rest lines" as LAGs in the bones. The presence of these lines in dinosaur bones has been taken as an indication that they were metabolically incapable of growing throughout the year. However, LAGs in dinosaurs are less pronounced than in other reptiles; LAGs can also appear in different numbers in different bones of the same skeleton, and they are sometimes even completely absent. Finally, some living birds and mammals, which are clearly endotherms, have LAGs very much like those of dinosaurs, so LAGs are probably not strong indicators of metabolism in any of these animals.

Fossil evidence of metabolism

Other, less direct lines of evidence may reveal other clues about dinosaurian metabolism. Two dinosaurian groups, the hadrosaurs and the ceratopsians, had highly specialized sets of teeth that were obviously effective at processing food. Both groups were herbivorous, but unlike living reptiles they chopped and ground foliage thoroughly. Such highly efficient dentitions may suggest a highly effective digestive process that would allow more energy to be extracted from the food. This feature by itself, however, may not be crucial. Pandas, for example, are not very efficient in digesting plant material, but they survive quite well on a diet of almost nothing but bamboo.

Another line of evidence is that dinosaurs had anatomic features reflecting a high capacity for activity. The first dinosaurs walked upright, holding their legs under their bodies; they could not sprawl. This indicates that, by standing and walking all day, they probably expended more energy than reptiles, which typically sit and wait for prey. As some lineages of dinosaurs grew larger, they reverted to four-legged (quadrupedal) locomotion, but their stance was still upright. They also put one foot directly in front of the other when they walked (parasagittal gait), instead of swinging the limbs to the side. Such posture and gait are present in all nonaquatic endotherms (mammals and birds) today, whereas a sprawling or semierect posture is typical of all ectotherms (reptiles and amphibians). Bipedal stance and parasagittal gait are not sustained in any living ectotherm, perhaps because they require a relatively higher level of sustained energy.

Circumstantial evidence of metabolism

The high speeds at which some dinosaurs must have traveled have also been invoked as evidence of high metabolic levels. For example, the ostrichlike dinosaurs, such as *Struthiomimus, Ornithomimus, Gallimimus,* and *Dromiceiomimus,* had long hind legs and must have been very fleet. The dromaeosaurs, such as *Deinonychus, Velociraptor,* and *Dromaeosaurus,* also were obligatory bipeds. They killed prey with talons on their feet, and one can argue that it must have taken a high level of metabolism to generate the degree of activity and agility required of such a skill. However, most ectotherms can move very rapidly in bursts of activity such as running and fighting, so this feature may not provide conclusive evidence either.

Related to the upright posture of many dinosaurs is the fact that the head was often positioned well above the level of the heart. In some sauropods (*Apatosaurus, Diplodocus, Brachiosaurus,* and *Barosaurus,* for instance), the brain must have been several metres above the heart. The phys-

iological importance of this is that a four-chambered heart would be required for pumping freshly oxygenated blood to the brain. Brain death follows very quickly when nerve cells are deprived of oxygen, and to prevent it most dinosaurs must have required two ventricles. In a four-chambered heart, one ventricle pumps oxygen-poor venous blood at low pressure to the lungs to absorb fresh oxygen (high pressure would rupture capillaries of the lungs). A powerful second ventricle pumps freshly oxygenated blood to all other parts of the body at high pressure. To overcome the weight of the column of blood that must be moved from the heart to the elevated brain, high pressure is certainly needed. In short, like birds and mammals, many dinosaurs apparently had the required four-chambered heart necessary for an animal with a high metabolism.

The significance of thermoregulation can be seen by comparing today's reptiles with mammals. The rate of metabolism is usually measured in terms of oxygen consumed per unit of body weight per unit of time. The resting metabolic rate for most mammals is about 10 times that of modern reptiles, and the range of metabolic rates among living mammals is about double that seen among reptiles. These differences mean that endothermic mammals have much more endurance than their cold-blooded counterparts. Some dinosaurs may have been so endowed, and although they seem to have possessed the cardiovascular system necessary for endothermy, that capacity does not conclusively prove that they were endothermic. There exists the possibility that dinosaurs were neither complete ectotherms nor complete endotherms. Rather, they may have evolved a range of metabolic strategies, much as mammals have (as is illustrated by the differences between sloths and cheetahs, bats and whales, for example).

Classification

The chief difference between the two major groups of dinosaurs is in the configuration of the pelvis. It was primarily on this distinction that the English biologist H.G. Seeley established the two dinosaurian orders and named them Saurischia ("lizard hips") and Ornithischia ("bird hips") in 1887; this differentiation is still maintained (Figure 4).

Pelvic structure of the two groups

As in all four-legged animals, the dinosaurian pelvis was a paired structure consisting of three separate bones on each side that attached to the sacrum of the backbone. The ilium was attached to the spine, and the pubis and ischium were below, forming a robust bony plate. At the centre of each plate was a deep cup—the hip socket (acetabulum). The hip socket faced outward and was open at its centre for the articulation of the thighbone. The combined saurischian pelvic bones presented a triangular outline as seen from the side, with the pubis extending down and forward and the ischium projecting down and backward from the hip socket. The massive ilium formed a deep vertical plate of bone to which the muscles of the pelvis, hind leg, and tail were attached. The pubis had a stout shaft, commonly terminating in a pronounced expansion or bootlike structure (presumably for muscle attachment) that solidly joined its opposite mate. The ischium was slightly less robust than the pubis, but it too joined its mate along a midline. There were minor variations in this structure between the various saurischians.

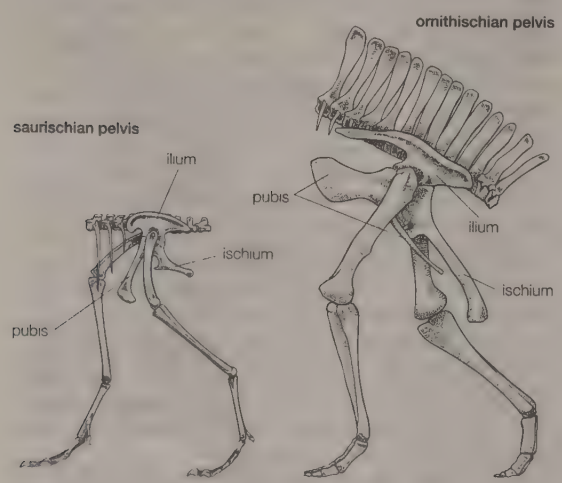


Figure 4: Dinosaur pelvic structures.
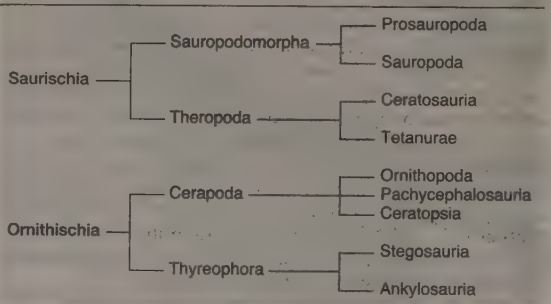
Encyclopædia Britannica

The ornithischian pelvis was constructed of the same three bones on each side of the sacral vertebrae, to which they were attached. The lateral profile of the pelvis was quite different from that of the saurischians, which had a long but low iliac blade above the hip socket and a modified ischium-pubis structure below. Here the long, thin ischium extended backward and slightly downward from the hip socket. In the most primitive, or basal, ornithischians, the pubis had a moderately long anterior blade, but this was reduced in later ornithischians. Posteriorly it stretched out into a long, thin postpubic process lying beneath and closely parallel to the ischium. The resulting configuration superficially resembled that of birds, whose pubis is a thin process extending backward beneath the larger ischium. These anatomic dissimilarities are thought to reflect important differences in muscle arrangements in the hips and hind legs of these two orders. However, the soft parts of these dinosaurs are not well enough understood to reveal any functional or physiological basis for the differences. Other marked dissimilarities between saurischians and ornithischians are found in their jaws and teeth, their limbs, and especially their skulls. Details regarding these differences are given in the following discussions of the major dinosaur groups.

Dinosaur subgroups



The table shows how the major dinosaur groups are subdivided. The table and classification (Figure 5) are based on the groups' relationships to each other, as far as they are known. Fossil remains are often difficult to interpret, especially when only a few fragmentary specimens of a type have been found. No universally accepted classification of dinosaurs exists. Occasionally, for example, the Sauropodomorpha have been divided into more or fewer lower-rank categories (*e.g.*, families, subfamilies), and the suborder Theropoda has been divided into two infraorders, the Carnosauria and the Coelurosauria. Increasingly, taxonomists have abandoned the traditional Linnaean ranks of family, order, and so on because they are cumbersome and not comparable among different kinds of organisms. Instead, the names of the groups alone are used without denoting a category. Generally, a phylogeny such as the accompanying diagram clearly shows which groups are subsumed under others. Additionally, words with similar roots but different endings may indicate more or less inclusive groups. Ornithomimosauria, for example, denotes a more inclusive group than Ornithomimidae. Because the results of different phylogenetic analyses vary among researchers, and will continue to change as new specimens and taxa are discovered, the classification can be expected to change accordingly. This is a normal part of scientific activity and reflects continuing growth of knowledge and reappraisal of current understanding.

SAURISCHIA

Saurischians are known from specimens ranging from the Late Triassic to the present day, because, as will be seen,

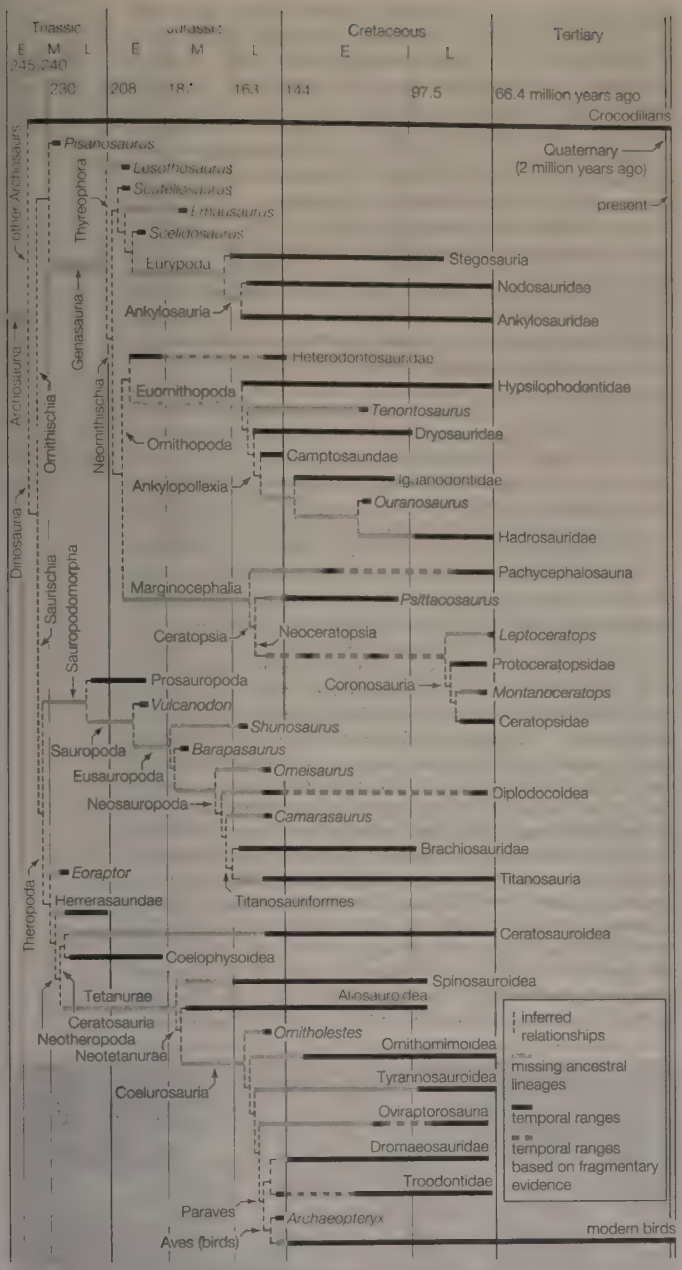


Figure 5: Dinosaur phylogeny, or "family tree."
Courtesy of Paul C. Sereno (2001), University of Chicago

birds are highly derived saurischian dinosaurs. Two distinctly different groups are traditionally included in the saurischians—the Sauropodomorpha (herbivorous sauropods and prosauropods) and the Theropoda (carnivorous dinosaurs). These groups are placed together on the basis of a suite of features that they share uniquely. These include elongated posterior neck vertebrae, accessory articulations on the trunk vertebrae, and a hand that is nearly half as long as the rest of the arm (or longer).

Sauropodomorpha. Included in this group are the well-known sauropods, or "brontosaur" types, and their probable ancestral group, the prosauropods. All were plant eaters, though their relationship to theropods, along with the fact that the closest relatives of dinosaurs were evidently carnivorous, suggests that they evolved from meat eaters. Sauropodomorpha are distinguished by leaf-shaped tooth crowns, a small head, and a neck that is at least as long as the trunk of the body and longer than the limbs.

Prosauropoda. Most generalized of the Sauropodomorpha were the so-called prosauropods. Found from the Late Triassic to Early Jurassic periods, their remains are probably the most ubiquitous of all Triassic dinosaurs. The best-known examples include *Plateosaurus* of Germany and *Massospondylus* of South Africa. Prosauropods were not especially large; they ranged from less than 2 metres (7 feet) in length up to about 8 metres (26 feet) and up to several tons in maximum weight. Many of these animals are known from very complete skeletons (especially the smaller, more lightly built forms). Because their forelimbs are conspicuously shorter than their hind limbs, they have often been reconstructed poised on their hind legs in a bipedal stance. Their anatomy, however, clearly indicates that some of them could assume a quadrupedal (four-footed) position. Footprints generally attributed to prosauropods appear to substantiate both forms of locomotion.

Possible sauropod ancestry

Prosauropods have long been seen as including the first direct ancestors of the giant sauropods, probably among the melanorosaurids. That view has long prevailed largely because of their distinctly primitive sauropod-like appearance and also because of their Late Triassic–Early Jurassic occurrence. No better candidate has been discovered, and the first true sauropods are not found until the Early Jurassic, so the transition between prosauropods and sauropods has been generally accepted. In the 1990s, however, several studies have suggested that prosauropods may be a distinct group that shared common ancestors with sauropods earlier in the Triassic. If this view is correct, it is mystifying why the smaller prosauropods are so widespread throughout the Late Triassic, yet none of the larger and more conspicuous sauropods have been found from that period.

In general body form, prosauropods were mostly rather stocky, with a long, moderately flexible neck containing surprisingly long and flexible cervical ribs. The head was small in comparison with the body. The jaw was long and contained rows of thin, leaflike teeth suited for chopping up (but not grinding or crushing) plant tissues, although there is an indication of direct tooth-on-tooth occlusion.

Prosauropod forelimbs were stout, with five complete digits. The hind limbs were about 50 percent longer than the forelimbs and even more heavily built. The foot was of primitive design, and its five-toed configuration could be interpreted as a forerunner of the sauropod foot. Walking apparently was done partly on the toes (semidigitigrade), with the metatarsus held well off the ground. The vertebral column was unspecialized and bore little indication of the cavernous excavations that were to come in later sauropod vertebrae, nor did it show projections that were to buttress the sauropod vertebral column. The long tail probably served as a counterweight or stabilizer whenever the animal assumed a bipedal position.

Sauropoda. The more widely known sauropods—the huge "brontosaurs" and their relatives—varied in length from 6 or 7 metres (about 20 feet) in the primitive ancestral sauropod *Vulcanodon* of Africa, *Barapasaurus* of India, and *Ohmdenosaurus* of Germany up to 28 to 30 metres (90 to 100 feet) or more in Late Jurassic North American forms such as *Apatosaurus* (formerly known as *Brontosaurus*), *Diplodocus, Seismosaurus,* and *Sauroposeidon.* Weights ranged from about 20 tons or less in *Barapasaurus* to 80 tons or more for the gigantic *Brachiosaurus* of Africa and North America (Figure 6). Sauropods were worldwide in distribution but have not as yet been found in Antarctica. In geologic time they ranged from the Late Triassic *Riojasaurus* to the Late Cretaceous *Alamosaurus* of North America and *Laplatasaurus* of South America. Their greatest diversity and abundance took place 120 million–150 million years ago, during the Late Jurassic and Early Cretaceous periods.

Sauropods are notable for their body form as well as their enormous size. Their large bodies were heart-shaped in cross section, like elephants, with long (sometimes extremely long) necks and tails. Their columnar legs, again like those of elephants, had little freedom to bend at the knee and elbow. The legs were maintained in a nearly vertical position beneath the shoulder and hip sockets. Because of their great bulk, sauropods unquestionably were obligate quadrupeds.

The sauropod limb bones were heavy and solid. The feet were broad, close to plantigrade (adapted for walking on

Figure 6: *Brachiosaurus* skeleton.

the soles), and graviportal (adapted for bearing great weight). The toes were generally short, blunt, and broad, but some sauropods had a large straight claw on the first digit of the forefoot and the first and second toes of the hind foot. These animals must have moved relatively slowly and with only short steps because of the comparative inflexibility of the limbs. Running must have been stiff-legged at no better than an elephantine pace of 16 km (10 miles) per hour, if that. Their tremendous bulk placed them out of the reach of predators and eliminated any need for speed. Evidently their fast growth was adaptive to predator avoidance.

Sauropod backbone and tail

The vertebrae of the backbone were highly modified, with numerous excavations and struts to reduce bone weight. Complex spines and projections for muscle and ligament attachment compensated for any loss of skeletal strength that resulted from reductions in bone density and mass. The long and sometimes massive tail, characteristic of so many sauropods, would appear to have been carried well off the ground. Tail drag marks associated with sauropod trackways are not known, and damaged (stepped-on) tails are also not known, even though these animals apparently traveled in herds (albeit of undetermined density). Another possible use of the tail, like the neck, may have been thermal regulation, as improved heat loss through its large surface area could have been a result. The tail was also the critical anchor of the large, powerful hind leg muscles that produced most of the walking force required for moving the many tons of sauropod weight. The muscle arrangement of the tail was precisely that of modern alligators and lizards.

The most important part of any skeleton is the skull because it provides the most information about an animal's mode of life and general biology. Sauropod skulls were of several main types, including the high, boxy *Camarasaurus* type (often incorrectly associated with *Apatosaurus*); the shoe-shaped *Brachiosaurus* type, with its large, delicately arched nasal bones; and the low, narrow, streamlined, almost horselike *Diplodocus* type. The first had broad, spatulate teeth, while the latter two had narrow, pencil-shaped teeth largely confined to the front parts of the jaws, especially in diplodocids.

Until recently, sauropods were visualized as swamp or lake dwellers because their legs were thought to be incapable of supporting their great weights or because such huge creatures would naturally prefer the buoyancy of watery surroundings. The 19th-century English biologist Richard Owen, in fact, identified the first known sauropods as giant aquatic crocodiles and called them cetiosaurs (whale lizards) because they were so large and because they were found in aquatic sediments. Eventually enough skeletal remains were discovered to show that these animals were neither crocodiles nor aquatic. However, the image of amphibious habits, thought necessary to support the great weights of sauropods, persisted for a long time, however incorrectly. Experiments with fresh bone samples have shown that bone of the type that composed the sauropods' limb bones could easily have supported their estimated weights. Moreover, there is no feature in their skeletons that suggests an aquatic, or even amphibious, existence. In addition, numerous trackway sites clearly prove that sauropods could navigate on land, or at least where the water was too shallow to buoy up their weight. Accordingly, newer interpretations see these animals as floodplain and forest inhabitants.

Still another blow has been dealt to the old swamp image by the physical laws of hydrostatic pressure, which prohibit the explanation that the long neck enabled a submerged animal to raise its head to the surface for a breath of fresh air. The depth at which the lungs would be submerged would not allow them to be expanded by normal atmospheric pressure, the only force that fills the lungs. Consequently, the long necks of sauropods must be explained in terms of terrestrial functions such as elevating the feeding apparatus or the eyes. On all counts, sauropods are best seen as successful giraffelike browsers and only occasional waders.

Theropoda. This group includes all the known carnivorous dinosaurs as well as the birds. No obviously adapted herbivores are recognized in the group, but some theropods, notably the toothless oviraptorids and ornithomimids, may well have been relatively omnivorous like today's ostriches. Mesozoic Era theropods ranged in size from the smallest known adult Mesozoic nonavian dinosaur, the crow-sized *Microraptor,* up to the great *Tyrannosaurus* and *Giganotosaurus,* which were 15 or more metres (50 feet) long, more than 5 metres (16 to 18 feet) tall, and weighed 6 tons or more (Figure 7). Theropods have been recovered from deposits of the Late Triassic through the latest Cretaceous and from all continents.

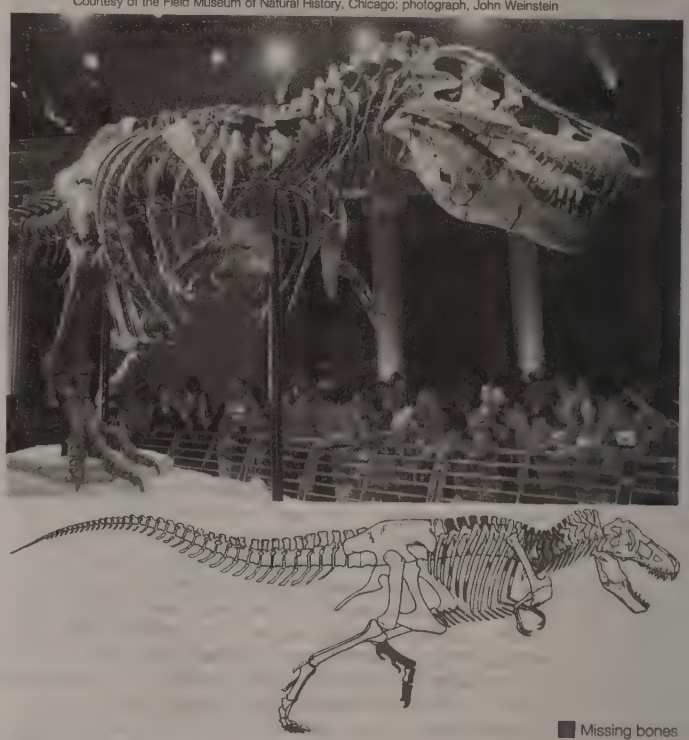

Figure 7: (Top) "Sue," a *Tyrannosaurus rex* skeleton found in South Dakota, U.S. (Bottom) Diagram of Sue's skeleton, indicating missing bones.

Theropods may be defined as birds and all saurischians more closely related to birds than to sauropods. They have a carnivorous dentition and large, recurved claws on the fingers. They also share many other characteristics, such as a distinctive joint in the lower jaw, epipophyses on the neck vertebrae, and a unique "transition point" in the tail where the vertebrae become longer and more lightly built. Other similarities include the reduction or loss of the outer two fingers, long end joints of the fingers, and a straplike fibula attached to a crest on the side of the tibia.

Herrerasaurus and several fragmentary taxa from South America, including *Staurikosaurus* and *Ischisaurus,* from the Middle to Late Triassic of Argentina are carnivores that have often been included in the Dinosauria, specifically in Theropoda. Whereas these animals closely resemble dinosaurs and have many carnivorous features, they also lack a number of features present in dinosaurs, saurischians, and theropods.

Theropod limbs

In stance and gait, theropods were obligatory bipeds. All had hind leg bones that were hollow to varying degrees—extremely hollow and lightly built in small to medium-size members (*Compsognathus, Coelurus,* and *Ornitholestes,* among others) and more solid in the larger forms (such as *Allosaurus, Daspletosaurus,* and *Tarbosaurus*). Their bodies conformed to a common shape in which the hind legs were dominant and designed for support and locomotion. The forelimbs, on the other hand, had been modified from the primitive design and entirely divested of the functions of locomotion and body support. Hind limbs were either very robust and of graviportal (weight-bearing) proportions, as in *Allosaurus, Megalosaurus,* and the tyrannosaurids, or very slender, elongated, and of cursorial (adapted for running) proportions, as in *Coelurus, Coelophysis, Ornitholestes,* and the ornithomimids. Theropod feet, despite the group's name, which means "beast (*i.e.,* mammal) foot," usually looked much like those of birds, which is not surprising, because birds inherited their foot structure from these dinosaurs. Three main toes were directed forward and splayed in a V-shaped arrangement; an additional inside toe was directed medially or backward. The whole foot was supported by the toes (digitigrade), with the "heel" elevated well above the ground. Toes usually bore sharp, somewhat curved claws.

The forelimbs varied widely from the slender, elongated ones of *Struthiomimus,* for example, to shorter, more massively constructed grasping appendages like those of *Allosaurus,* to the greatly abbreviated arms and hands of *Tyrannosaurus,* to the abbreviated, stout limb and single finger of *Mononykus,* to the range of wings now seen in birds. The hands typically featured long, flexible fingers with pronounced, often strongly curved claws, which bore sharp piercing talons. Early theropods such as *Coelophysis* had four fingers, with the fifth reduced to a nubbin of the metacarpal and the fourth greatly reduced. Most theropods were three-fingered, having lost all remnants of the fourth and fifth fingers. Tyrannosaurids (including *Albertosaurus, Daspletosaurus, Tarbosaurus,* and *Tyrannosaurus*) were notable for their two-fingered hands and unusually short arms; they had lost the third finger. The odd *Mononykus* lost even its second finger, retaining only a bizarre thumb. This separation of function between fore and hind limbs was a feature of the first dinosaurs. Although the first theropods, sauropodomorphs, and ornithischians were all bipedal, only theropods remained exclusively so.

The jaws of theropods are noted for their complement of sharp, bladelike teeth. In nearly all theropods these laterally compressed blades had serrations along the rear edge and often along the front edge as well. Tyrannosaur teeth differed in having a rounder, less-compressed cross section, better adapted to puncture flesh and tear it from bone. Troodontid teeth had recurved serrations slightly larger than those typical of theropods. *Archaeopteryx* and other basal birds had narrow-waisted teeth with greatly reduced serrations or none at all. Some theropods, such as most ornithomimids and oviraptorids, had lost most or all of their teeth.

In recent years a series of unusually well-preserved theropod dinosaurs have been discovered in deposits from the Early Cretaceous Period (144 million to 97.5 million years ago) in Liaoning province, China. These theropods have filamentous integumentary structures of several kinds that resemble feathers. Such structures indicate that today's birds very likely evolved from theropod dinosaurs. See above *Dinosaur descendants.*

Ceratosauria. Ceratosauria includes *Ceratosaurus* and all theropods more closely related to it than to birds. This group includes basal theropods such as *Coelophysis* and *Dilophosaurus.* It may also include the abelisaurids of South America and elsewhere, but this is not certain. Originally thought to be a natural group, Ceratosauria, as traditionally constituted, may represent a more general grouping of basal theropods, including the ancestral stock of most later theropods. The Late Triassic *Coelophysis,* about 1.5 meters long, is generally regarded as an archetypal primitive theropod. It had a long neck and a long, low head with numerous small, sharp, recurved teeth. The legs were long, the arms relatively short, and the tail very long. *Dilophosaurus,* from the Early Jurassic Period (208 million to 187 million years ago), is considerably larger (about 4 metres total length) and is distinguished by a pair of thin bony crests running along the top of the skull. Because no other theropod had such structures, these were apparently not necessary for any physiological function and so are thought to have been for display or species recognition. There is no evidence that *Dilophosaurus* spat venom.

Tetanurae. These comprise birds and all the theropods closer to birds than to *Ceratosaurus.* They would include the true carnosaurs and coelurosaurs described below as well as a few relatively large carnivorous basal forms (such as *Torvosaurus, Spinosaurus, Baryonyx, Afrovenator,* and *Megalosaurus*). The tetanuran theropods are distinguished by several features, including the complete loss of digits four and five of the hand, an upper tooth row extending backward only to the eye, and a fibula that is reduced and clasped by the tibia. The name Tetanurae, or "stiff tails," refers to another unusual feature, a transition point in the tail sequence where the vertebrae change form in a distinctive way.

Carnosaurs

Carnosauria includes *Allosaurus* and all theropods more closely related to it than to birds, including forms such as *Acrocanthosaurus, Sinraptor,* and *Giganotosaurus.* The first known members appear in the Late Jurassic and persist into the Cretaceous. Originally, this group was designed to include all the big predatory dinosaurs, but it was recently recognized that only size, not their relationships, was the trait unifying this group. Some, such as *Dilophosaurus* and *Carnotaurus,* were probably more closely related to basal ceratosaurs. Others, such as *Baryonyx* and *Spinosaurus,* represented an unusual diversification of fish-eating forms that were almost crocodilian in some of their habits. Still others, such as *Tyrannosaurus* and its relatives, the albertosaurs and daspletosaurs, were probably just giant coelurosaurs, as had been hypothesized by German paleontologist Friedrich von Huene early in the 20th century. As these groups were removed from the original Carnosauria, only *Allosaurus* and its relatives of the great Late Jurassic and Early Cretaceous diversification were left. Along with *Torvosaurus* and the megalosaurs, they must have been among the most deadly and rapacious large predators of their time. They are distinguished by relatively few characteristics. It is commonly thought that carnosaurs had very short limbs, but this is not particularly true—they were proportionally much shorter in tyrannosaurs, which are no longer considered carnosaurs. True carnosaurs had limbs comparable in size to those of more basal theropods. Sauropod vertebrae have been found with carnosaur tooth marks in them, which attests to the predatory habits of these dinosaurs.

The coelurosaurs ("hollow-tailed reptiles") include generally small to medium-size theropods, though the recent inclusion of tyrannosaurs would seem to discount this generalization. Coelurosauria is defined as birds and all tetanurans more closely related to birds than to the carnosaurs. The first known members, including birds, appear in the Late Jurassic; the great Cretaceous diversification of the other coelurosaurs ended with the Cretaceous extinctions.

In coelurosaurs the pelvis is modified so that the ischium is reduced to two-thirds or less the size of the pubis; the

eyes are larger, and no more than 15 tail vertebrae bear transverse projections. Each of the various coelurosaurian groups has very distinct features that set it apart from the others. The most basal known form, the Late Jurassic *Compsognathus,* was the size of a chicken and contemporaneous with the first known bird, *Archaeopteryx.* However, the two animals were not as closely related as some other coelurosaurs were to birds.

Tyrannosaurs and the related albertosaurs were the largest of the Late Cretaceous theropods of the northern continents. They are distinguished by an exceptionally large, high skull and teeth with a much more rounded cross section than the typical daggerlike teeth of other theropods. Their forelimbs are very short, and the third finger is reduced to a splint or lost entirely. Tyrannosaurs are thought to have migrated to North America from Asia, because early relatives first appear on the latter continent. Although there has been some debate about whether tyrannosaurs were active predators or more passive scavengers, the distinction is not usually strong in living predatory animals, and frequently larger carnivores will chase smaller ones away from fresh kills. However, some skeletons of plant-eating dinosaurs evidently have healed wounds caused by tyrannosaur bites, so active predation appears to be sustained.

Ornithomimids were medium-size to large theropods. Almost all of them were toothless, and apparently their jaws were covered by a horny beak; they also had very long legs and arms. A well-known example is *Struthiomimus.* Most were ostrich-sized and were adapted for fast running, with particularly long foot bones, or metatarsals. The largest was *Deinocheirus* from Asia, known only from one specimen consisting of complete arms and hands almost 3 metres (10 feet) long—nearly four times longer than those of *Struthiomimus.* These animals' speed, toothlessness, and long hands with relatively symmetrical fingers leave their lifestyle and feeding habits unclear, but they may have been fairly omnivorous like ostriches, although they are not directly related.

Oviraptorids, therizinosaurids, and caenagnathids appear to form a group slightly more related to birds than to the coelurosaurs. Oviraptorids, known from the Late Cretaceous of Mongolia, had very strange skulls, often with high crests and a reduced dentition in an oddly curved jaw. The name oviraptor means "egg stealer," and it was given because remains of this carnivorous dinosaur were found along with fossil eggs presumed to belong to a small ceratopsian, *Protoceratops,* which lay nearby. Recent discoveries in Mongolia of oviraptorids sitting in birdlike positions on nests of eggs formerly thought to belong to *Protoceratops* reveal that the parentage was misplaced and that oviraptorids, like their bird relatives, apparently tended their young. Therizinosaurids, or segnosaurs, and caenagnathids are known from only a few specimens.

Figure 8: (Top) Rendering of *Velociraptor* and (bottom) reconstruction of its skeleton.

The maniraptorans comprise birds, dromaeosaurs, and troodontids. Dromaeosaurs were medium-size predators with long, grasping arms and hands, moderately long legs, and a specialized stiffened tail that could be used for active balance control. Their feet bore large talons on one toe that were evidently used for raking and slicing prey. A famous discovery known as the "fighting dinosaurs of Mongolia" features a small dromaeosaur, *Velociraptor,* locked in petrified combat with a small protoceratopsian. The hands of the dromaeosaur are grasping the beaked dinosaur's frill, and the foot talons are apparently lodged in its throat. The best-known examples are *Deinonychus* of North America and *Velociraptor* of Asia (Figure 8).

ORNITHISCHIA

The Ornithischia were all plant eaters, as far as is known. In addition to a common pelvic structure, they share a number of other unique features, including a bone that joined the two lower jaws and distinctive leaf-shaped teeth crenulated along the upper edges. They had at least one palpebral, or "eyelid," bone, reduced skull openings near the eyes and in the lower jaw (antorbital and mandibular), five or more sacral vertebrae, and a pubis whose main shaft points backward and down, parallel to the ischium. The earliest and most basal form is the incompletely known *Pisanosaurus,* from the Late Triassic of Argentina. Other primitive forms also existed, but the two main ornithischian lineages are the Cerapoda and Thyreophora.

Cerapoda. Cerapoda is divided into three groups: Ornithopoda, Pachycephalosauria, and Ceratopsia. The latter two are sometimes grouped together as Marginocephalia because they share a few features, including a bony shelf on the back of the skull.

Ornithopoda. Ornithopods include heterodontosaurs, known from southern Africa; the slightly larger hypsilophodontids, about three metres in length; the much larger iguanodontids, about nine metres long, mostly from North America and Europe; and the large duck-billed hadrosaurs of North America and Eurasia.

The postcranial anatomy of the ornithopods reflects the bipedal ancestry of the group, but the giant hadrosaurs and some iguanodontids may have been as comfortable on four legs as on two, especially while feeding on low vegetation. All members had hind legs that were much longer and sturdier than their forelegs. The thighbone (femur) was nearly always shorter than the shinbones (tibia and fibula), especially in all but the largest forms. The tail was long and sometimes quite deep and flat-sided. The vertebral spines of the tail and trunk region were reinforced by a rhomboidal latticework of bony (ossified) tendons running in criss-cross fashion between adjacent spines. They suggest a certain degree of stiffening of the tail and backbone, which were balanced over the massive hips.

Ornithopod vs. theropod feet

Ornithopod feet were modified from the primitive five-toed pattern in a way that resembled similar modifications in theropod feet. The three middle toes served as the functional foot; the inside toe was shortened and often held off the ground, and the outside toe was greatly reduced or absent altogether. The resemblance to theropod feet is so strong that the footprints of the two groups are easily confused, especially if poorly preserved. The toes of all but the most basal ornithopods terminated in broad, almost hooflike bones, especially in the duckbills, as opposed to the sharp claws of theropods, and this is one way to distinguish their footprints. The hand reflected the primitive five-digit design, and, as was generally true in archosaurs, the fourth and fifth digits were shorter than the other three, with the third being longest. In iguanodontids and hadrosaurs, the fingers ended in broad, blunt bones rather than in claws, much like the toes. It is thought that these middle fingers and toes were covered by blunt, hooflike structures. In the duckbills the fingers apparently were encased in a mittenlike structure that could have broadened the hand for better support of the animal's weight on soft ground.

The Ornithopoda differ from one another mainly in the structure of their skulls, their jaws and teeth, their hands and feet, and their pelvises. Ornithopods constitute an excellent case study in evolution because, as the various lin-

eages arise and die out from the latest Triassic to the latest Cretaceous, trends in size, complications and elaborations of teeth and chewing mechanisms, adaptations for quadrupedal posture in some forms, and other changes emerge clearly from their phylogenetic patterns.

In the fabrosaurids the teeth were simple leaf-shaped, laterally compressed elements arranged in a single front-to-back row in each jaw. They were not set in from the outer cheek surface as in most ornithopods. Upper and lower teeth alternated in position when the jaw was closed; they did not occlude directly.

In heterodontosaurs the cheek teeth were crowded together into long rows and set inward slightly from the outer cheek surface. The inset, which persisted through all later ornithopods, has been interpreted to suggest the presence of cheeks that may have held plant food in the mouth for further processing by the cheek teeth. They occluded directly to form distinct chisel-like cutting edges with a self-sharpening mechanism maintained by hard enamel on the outer side of the upper teeth and the inner side of the lower. There were prominent upper and lower tusklike teeth at the front of the mouth (the upper set in the premaxillary bones, the lower on the dentary bones). At least two pairs of incisors seem to have been retained. Certain features of the skull suggest much larger jaw muscles in heterodontosaurs than in the fabrosaurids.

The hypsilophodonts had cheek teeth arranged in tightly packed rows set well inward from the outer cheek surfaces. The teeth occluded directly, and the opposing rows formed a long shearing edge similar to that of the heterodontosaurs. There was, however, no "tusk" either above or below. The premaxillaries had small simple incisor-like teeth above the beak-covered, toothless predentary. Strong projections of bone extended up from the lower jaw toward the moderate-size upper temporal fenestrae.

The skulls of iguanodonts accommodated still larger jaw muscles, but the cheek teeth were less regular and compacted than in the primitive ornithopods and consequently did not occlude as uniformly. Both the premaxillaries and the predentary were toothless but probably were sheathed in horny beaks.

Hadrosaur teeth

Specialization of the teeth and jaws reached a pinnacle in the hadrosaurs, or duck-billed ornithopods. In this group a very prominent, robust projection jutted from the back of the stout lower jaw. Large chambers housing muscles were present above this process and beneath certain openings in the skull (the lateral and upper temporal fenestrae). These chambers are clear evidence of powerful jaw muscles. The dentition consisted of numerous tightly compacted teeth crowded into large grinding batteries. The battery in each jaw was composed of as many as 200 functional and replacement teeth with distinct, well-defined wear, or grinding, surfaces that resulted from very exact occlusion. As teeth were lost from the front of the jaws in iguanodontids and hadrosaurs, the snouts expanded into a bulbous shape, especially in the "duck-billed" hadrosaur, and may have been covered by a horny beak that improved feeding. These bills apparently had edges sharp enough to shred and strip leaves or needles from low shrubs and branches. Pine needles have been identified in duck-billed dinosaur remains and presumably represent stomach contents.

Other interesting specializations may have assisted iguanodontids and hadrosaurs in feeding. The hands were unusually modified in the two groups, though in different ways. In iguanodontids the wrist bones were coalesced into a single blocky structure that was less mobile than in more primitive wrist configurations. The joints of the thumb were similarly coalesced into a single conelike spike that had limited mobility on the wrist. The middle three digits flexed in the normal way and bore broad flat, spatulate claws. The fifth digit actually had two additional joints and became somewhat opposable to the rest of the hand. It is thought that the hands may have been adapted to grasp and strip vegetation, and the spikelike thumb has been suggested to have been an effective weapon against predators. These features were more or less continued in hadrosaurs, except in this group the blocky wrist was reduced and the thumb was lost completely.

Some varieties of hadrosaurs are also noted for the peculiar crests and projections on the top of the head (Figure 9). These structures were expansions of the skull composed almost entirely of the nasal bones. In genera such as *Corythosaurus, Lambeosaurus, Parasaurolophus* (and a few others), the crests were hollow, containing a series of middle and outer chambers that formed a convoluted passage from the nostrils to the trachea. Except for passing air along to the lungs, the function of these crests is not widely agreed upon. Sound production (honking), an improved sense of smell, and a visually conspicuous ornament for species recognition are some suggestions. Because these animals are no longer considered to have been amphibious, ideas such as snorkeling and extra air storage space have generally been discarded. Besides, the crests had no opening at their ends and consequently would not have been able to work as snorkels; even the largest crests held only an estimated 2 percent of the volume of the lungs, hardly enough to justify the construction of such an elaborate structure.

Figure 9: Skulls of a hadrosaur (*Parasaurolophus*) and a pachycephalosaur (*Stegoceras*).

Pachycephalosauria. In important respects the pachycephalosaurs conformed to the basic ornithopod body plan, and there is some evidence that pachycephalosaurs actually evolved from (and are therefore members of) ornithopods, perhaps similar to hypsilophodontids. All of them appear to have been bipedal. They bore the typical ornithopod ossified tendons along the back, and they had simple leaf-shaped teeth, although the teeth were enameled on both sides. The ornithischian type of pelvis was present, but a portion of the ischium was not.

The pachycephalosaurs are known as domeheads because of their most distinctive feature—a marked thickening of the frontoparietal (forehead) bones of the skull (Figure 9). The thickness of bone was much greater than might be expected in animals of their size. The suggestion has been made that this forehead swelling served as protection against the impact of the type of head-butting activities seen today in animals such as bighorn sheep, but microscopic studies of the bone structure of these thick domes suggest that they are poorly designed to divert stresses away from the braincase. Also, the great variety of pachycephalosaur domes—from thin, flat skull tops to pointed ridges with large spikes and knobs facing down and back—suggests no single function in defense or combat.

Stegoceras and *Pachycephalosaurus* of the North American Cretaceous were, respectively, the smallest and largest members of the group, the former attaining a length of about 2.5 metres (8 feet) and the latter twice that. Pachycephalosaurs are known almost entirely from the Late Cre-

taceous (although *Yaverlandia* is from the Early Cretaceous) and have been found in North America and Asia. They are generally rare and still are relatively poorly known among dinosaur groups.

Ceratopsia. The first ceratopsian ("horn-faced") dinosaur remains were found in the 1870s by the American paleontologist Edward D. Cope, who named the animal *Agathaumus,* but the material was so fragmentary that its unusual design was not at once recognized. The first inkling that there had been horned dinosaurs did not emerge until the late 1880s with the discovery of a large horn core, first mistaken for that of a bison. Shortly afterward, dozens of large skulls with horns were found—the first of many specimens of *Triceratops* (Figure 10).

Figure 10: *Triceratops* skeleton.

Ceratopsians first appeared in the modest form of psittacosaurids, or parrot-reptiles, in the Early Cretaceous and survived to the "great extinction" at the end of the Cretaceous Period. *Triceratops,* together with *Tyrannosaurus,* was one of the very last of all known Mesozoic Era dinosaurs in North America, where the fossil record of the latest Cretaceous is best known. Ceratopsians had a peculiar geographic distribution: the earliest and most primitive kinds, such as *Psittacosaurus,* are known only from Asia—Mongolia and China, specifically. *Protoceratops* and its relatives are known from both Asia and North America. All the advanced ceratopsids (chasmosaurines and centrosaurines), with the exception of a few fragmentary and doubtful specimens, have been found only in North America.

Ceratopsians ranged in size from relatively small animals the size of a dog to the nearly 9-metre- (30-foot-) long, four- to five-ton *Triceratops.* Although commonly compared to the modern rhinoceros, *Triceratops* grew to a weight and bulk several times that of the largest living rhinoceros, and its behaviour probably was correspondingly different. The most distinctive feature of nearly all members of the group was the horns on the head, hence the name *ceratops.* Correlated with the various arrays of head horns in the different taxa was the unusually large size of ceratopsian heads. Great bony growths extended from the back of the skull, reaching well over the neck and shoulders. This neck shield, or frill, resulted in the longest head that ever adorned any land animal; the length of the *Torosaurus* skull was almost 3 metres (10 feet), longer than a whole adult *Protoceratops.*

Purpose of the neck frill

Several hypotheses have been proposed to explain this frill structure: a protective shield to cover the neck region, an attachment site of greatly enlarged jaw muscles, an attachment site of powerful neck muscles for wielding the head horns, or a sort of ornament to present a huge, frightening head-on profile to potential attackers. The most unusual thought is that the structure was none of these but rather acted as a giant heat-control apparatus, with its entire upper surface covered in a vast network of blood vessels pulsing with overheated blood or absorbing solar heat.

Most of these hypotheses are difficult to test. One important fact to keep in mind was that the frill was little more than a frame of bone, sometimes ornamented with knobs and spikes around large openings behind and above the skull. An exception to this pattern was *Triceratops,* which had a solid and relatively short frill, but *Triceratops* is so well known that its frill is often mistakenly considered typical of ceratopsians. The open frill of other ceratopsians would have provided only poor protection for the neck region and only a modest area of attachment for jaw or neck muscles. If skin and soft tissues spanned the area framed by the bony frill, it would have created a formidable presence when the head was lowered in threatening display. Such a large structure would naturally have absorbed and reflected sunlight that warmed the tissue and its internal blood vessels, but it is questionable whether this was an important or necessary function of the frill, since other dinosaurs do not have similar structures.

The Ceratopsia are divided into groups that mirror their evolutionary trends through time: the primitive psittacosaurids, such as *Psittacosaurus;* the protoceratopsids, including *Protoceratops* of Asia and *Leptoceratops* of North America; and the ceratopsids, encompassing all the advanced and better-known kinds such as the chasmosaurines *Triceratops* and *Torosaurus* as well as the centrosaurines such as *Centrosaurus* (or *Monoclonius*)—all from North America.

Like the pachycephalosaurs, the most basal ceratopsians, such as *Psittacosaurus,* look much like typical ornithopods, largely because of their relatively long hind limbs and short front limbs (probably resulting in bipedal stance and locomotion) and the persistence of upper front teeth and a fairly unspecialized pelvis. *Psittacosaurus,* however, possessed a beak, the beginnings of a characteristic neck frill at the back of the skull, and teeth that prefigured those of the more advanced ceratopsians. It is also recognized diagnostically as a ceratopsian by the presence of a unique bone called the rostral, a toothless upper beak bone that opposed the lower predentary found in all ornithischians.

The best-known of the protoceratopsids is the genus *Protoceratops.* Dozens of skeletal specimens, ranging from near hatchlings to full-size adults, have been found and studied. This rare treasure, the first to include very young individuals unmistakably associated with mature individuals, was the result of the series of American Museum of Natural History expeditions in the 1920s to the Gobi Desert of Mongolia. Their collection provided the first valid growth series of any dinosaur. Their discovery of several nests of eggs loosely associated with *Protoceratops* skeletons was the first finding of eggs that were unquestionably dinosaurian; originally attributed to *Protoceratops,* the eggs only recently were correctly attributed to the theropod *Oviraptor* (as noted in the section Tetanurae).

The skeletal anatomy of the protoceratopsids foreshadowed that of the more advanced ceratopsids. The ceratopsian skull was disproportionately large for the rest of the animal, constituting about one-fifth of the total body length in *Protoceratops* and at least one-third in *Torosaurus.* The head frill of *Protoceratops* was a modest backward extension of two cranial arches, but it became the enormous fan-shaped ornament of later forms, including *Triceratops.* The advanced ceratopsids are sometimes divided into centrosaurines, which had a prominent nose horn but small or absent eye horns, and chasmosaurines, which had larger eye horns but reduced nose horns.

Ceratopsian jaws

Ceratopsian jaws were highly specialized. The lower jaw was massive and solid to support a large battery of teeth similar to those of the duckbills. The lower jawbones were joined at the front and capped by a stout beak formed of the toothless predentary bone. This structure itself must have been covered by a sharp, horny, turtlelike beak. Continuous dental surfaces extended over the rear two-thirds of the jaw. The tooth batteries, however, differed from those of the hadrosaurs in forming long, vertical slicing surfaces as upper and lower batteries met, operating much like self-sharpening shears.

As in the hadrosaurs, each dental battery consisted of about two dozen or more tooth positions compressed together into a single large block. At each tooth position there was one functional, or occluding, tooth (the duckbills had two or three) along with several more unerupted replacement teeth beneath. (All toothed vertebrates, living and extinct, except mammals, have a lifelong supply of re-

placement teeth.) The suggestion is that they fed on something exceedingly tough and fibrous, such as the fronds of palms or cycads, both of which were plentiful during late Mesozoic times.

With the exception of the bipedal *Psittacosaurus,* and perhaps the facultatively bipedal protoceratopsids, all ceratopsians were obligate quadrupeds with a heavy, ponderous build. The leg bones were stout and the legs themselves muscular; the feet were semiplantigrade for graviportal stance and progression; and all the toes ended in "hooves" rather than claws. As in most other four-legged animals, the rear legs were significantly longer than the front legs (which again suggests their bipedal ancestry). The hind legs were positioned directly beneath the hip sockets and held almost straight and vertical. The front legs, on the other hand, projected out to each side from the shoulder sockets in a "push-up" position. Consequently, the head was carried low and close to the ground. This mixed posture was perhaps related to the large horned head and its role in combat, the bent forelegs providing a wide stance and stable base for directing the horns at an opponent and resisting attack.

The first four neck vertebrae of ceratopsians were fused (co-ossified), presumably to support the massive skull. The first joint of the neck was unusual in that the bone at the base of the skull formed a nearly perfect sphere that fit into a cuplike socket of the fused neck vertebrae. Such an arrangement would seem to have provided solid connections along with maximum freedom of the head to pivot in any direction without having to turn the body. Presumably ceratopsians used their horns in an aggressive manner, but whether they used them as defense against possible predators, in rutting combat with other male ceratopsians, or in both is not so clear. Evidence of puncture wounds in some specimens suggests rutting encounters, but the fact that both sexes apparently had horns seems to indicate defense or species recognition as their primary uses.

Thyreophora. The Thyreophora consist mainly of the well-known Stegosauria, the plated dinosaurs, and Ankylosauria, the armoured dinosaurs, as well as their more basal relatives, including *Scutellosaurus* and *Scelidosaurus.* Both possessed small bony plates, or scutes, along the body.

In the Middle and Late Jurassic, the first stegosaurs and ankylosaurs appeared. Like the previously described forms, they are distinguished by bony scutes. Scutes are maintained and elaborated all over the body in ankylosaurs but are reduced to a series of plates and spikes along the backbone in stegosaurs, though their basic structure remains the same in both groups. Thyreophorans also have low, flat skulls, simple S-shaped tooth rows with small leaf-shaped tooth crowns, and spout-shaped snouts.

Stegosauria. With their unique bony back plates, the stegosaurs are very distinctive. Relatively few specimens have been found, but they were widespread, with remains being found in North America, Africa, Europe, and Asia. Stegosaurian remains have appeared in Early Jurassic to Early Cretaceous strata. The most familiar genus is *Stegosaurus,* found in the Morrison Formation (Late Jurassic) of western North America. *Stegosaurus* was 3.7 metres (12 feet) in height and 9 metres in length, probably weighed two tons, and had a broad, deep body (Figure 11). Not all varieties of the Stegosauria were this large; for example, *Kentrosaurus,* from eastern Africa, was less than 2 metres high and 3.5 metres long.

Courtesy, Library Services Department, American Museum of Natural History, New York City; photograph, O. Bauer and R. Sheridan (Neg. No. 2A 13019)

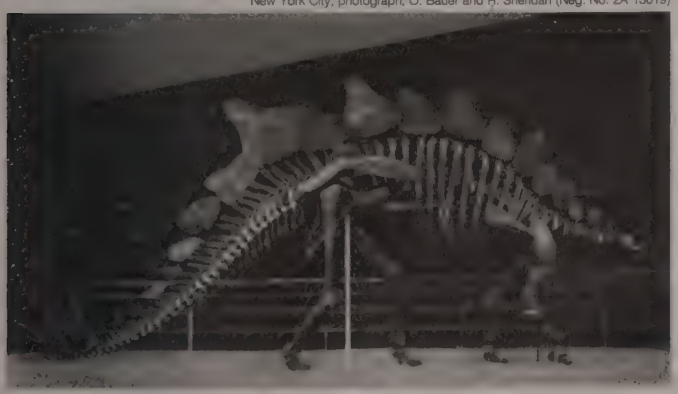

Figure 11: *Stegosaurus* skeleton.

All stegosaurs were graviportal and undoubtedly quadrupedal, although the massive legs were of greatly disparate lengths—the hind legs being more than twice the length of the forelegs. Whatever walking and running skills were possessed by the stegosaurs, their limb proportions must have made these movements extremely slow. The humerus of the upper arm was longer than the bones of the forearm, the femur much longer than the shinbones, and certain bones of the feet very short, which means that the stride must have been short. In addition, the feet were graviportal in design and showed no adaptations for running.

The stegosaurian skull was notably small, long, low, and narrow, with little space for sizable jaw muscles. The weakly developed dentition consisted of small, laterally compressed, leaf-shaped teeth arranged in short, straight rows. This combination of features seems odd in comparison with the large, bulky body. The weak dentition suggests that the food eaten must have required little preparation by the teeth and yet provided adequate nourishment. Perhaps the digestive tract contained fermenting bacteria capable of breaking down the cellulose-rich Jurassic plant tissues. Digestion may also have been assisted by a crop or gizzard full of pulverizing stomach stones (gastroliths), though none has yet been discovered in stegosaurian specimens. A collection of disklike bones is found in the throat region of *Stegosaurus,* but these are likely to have been embedded in the skin, not used in the gut. Even so, it is still difficult to understand how these animals, with such small and poorly equipped mouths, could have fed themselves adequately to sustain their great bulk. The same problem has been encountered in speculations about the feeding habits of sauropods.

Purpose of the dorsal plates

The most distinctive stegosaurian feature was the double row of large diamond-shaped bony plates on the back. A controversy as to their purpose and how they were arranged has raged ever since the first *Stegosaurus* specimen was collected in 1877 by Marsh's workers at the Morrison Formation in Colorado, U.S. The evidence and a general consensus argue in favour of the traditional idea that the plates projected upward and were set in two staggered (alternating) rows on either side of the backbone. In other stegosaurs, such as *Kentrosaurus,* the plates are more symmetrical and may have been arranged side by side. The suggestion that the plates did not project above the back at all, but lay flat to form flank armour, has been rejected on the basis of studies of the microstructure of the bone of the plates, in which attachment fibres are embedded in a manner consistent with an upright position. In *Stegosaurus* itself, the end of the tail bore at least two pairs of long bony spikes, which suggests some sort of defensive role for the tail but not necessarily for the back plates. However, other stegosaurs, such as *Kentrosaurus,* had relatively small plates along the front half of the spine and spikes along the back half of the spine and the tail.

The discovery in 1976 that the bony plates of *Stegosaurus* were highly vascularized led to the suggestion that these "fins" functioned as cooling vanes to dissipate excess body heat in much the same way that the ears of elephants do. The staggered arrangement in parallel rows might have maximized the area of cooling surface by minimizing any downwind "breeze shadow" that would have resulted from a paired configuration. Asymmetry is a bizarre anatomic condition, and, right or wrong, this certainly is an imaginative explanation of its presence in this animal. No other stegosaur, however, had such a peculiar feature. Rather, all other taxa had a variety of paired body spikes that seem best explained as passive defense or display adaptations rather than cooling mechanisms.

Ankylosauria. The ankylosaurs are known from the Late Jurassic and Cretaceous periods. They are called "armoured dinosaurs" for their extensive mosaic of small and large interlocking bony plates that completely encased the back and flanks. Most ankylosaurs, such as *Euoplocephalus, Nodosaurus,* and *Palaeoscincus,* were relatively

low and broad in body form and walked close to the ground on short, stocky legs in a quadrupedal stance. As in stegosaurs, the hind legs were longer than the front legs, but they were not as disproportionate as those of *Stegosaurus*. Like the stegosaurs, however, their limbs were stout and columnar, the thighbone and upper arm were longer than the shin and forearm, and the metapodials were stubby. These features point to a slow, graviportal mode of locomotion. The feet were semiplantigrade and possibly supported from beneath by pads of cartilage. The bones at the ends of the digits (terminal phalanges) were broad and hooflike rather than clawlike.

The ankylosaur skull was low, broad, and boxlike, with dermal scutes (osteoderms) that were often fused to the underlying skull bones. In *Euoplocephalus* even the eyelid seems to have developed a protective bony covering. The jaws were weak, with a very small predentary and no significant projections of bone for jaw muscle attachment. The small jaw muscle chamber was largely covered by dermal bones rather than having openings. The teeth were small, loosely spaced, leaf-shaped structures reminiscent of the earliest primitive ornithischian teeth. All taxa had very few teeth in either jaw, in marked contrast to the highly specialized, numerous teeth of other ornithischians. These features of the jaws and teeth lead to the impression that the animals must have fed on some sort of soft, pulpy plant food.

Apparently neither very diverse nor abundant, the ankylosaurs are known only from North America, Europe, and Asia. They are divided into the more basal Nodosauridae and the more advanced Ankylosauridae, which may have evolved from nodosaurs. The most conspicuous difference between the two groups is the presence of a massive bony club at the end of the tail in the advanced ankylosaurs; no such tail structure is present in the nodosaurs. The patterns of the armour also generally differ between the two groups, and ankylosaurids tend to have even broader, more bone-encrusted skulls than did the nodosaurs.

BIBLIOGRAPHY

General works. PHILIP J. CURRIE and KEVIN PADIAN (eds.), *Encyclopedia of Dinosaurs* (1997), comprises articles on topics related to dinosaur taxonomy, biology, and evolution as well as important paleontological sites and exhibits worldwide. JAMES O. FARLOW and M.K. BRETT-SURMAN (eds.), *The Complete Dinosaur* (1997), emphasizes aspects of various groups of dinosaurs and their biology. DAVID NORMAN and JOHN SIBBICK, *The Illustrated Encyclopedia of Dinosaurs: An Original and Compelling Insight into Life in the Dinosaur Kingdom* (1985, reissued 1998), provides a well-written and lavishly illustrated treatment that is excellent for the specialist and nonspecialist alike.

Advanced textbooks on vertebrate evolution and paleontology include MICHAEL J. BENTON, *Vertebrate Palaeontology*, 2nd ed. (1997, reissued 2000); and ROBERT L. CARROLL, *Vertebrate Paleontology and Evolution* (1988). DAVID B. WEISHAMPEL, PETER DODSON, and HALSZKA OSMÓLSKA (eds.), *The Dinosauria* (1990), primarily contains extensive reviews of the major taxonomic groups, defining them via anatomic descriptions and drawings while also supplying fossil-site information.

The search for dinosaurs. LOUIE PSIHOYOS and JOHN KNOEBBER, *Hunting Dinosaurs* (1994), assembles an impressive photographic record of the discoveries and the people responsible for them. PHILIPPE TAQUET, *Dinosaur Impressions: Postcards from a Paleontologist* (1998; originally published in French, 1994), vividly traces one paleontologist's travels throughout the world over a period of 30 years. EDWIN H. COLBERT, *Dinosaurs: Their Discovery and Their World* (1961), a landmark treatment of the subject by a world authority of the period, includes extensive photographic and line-drawing coverage, and *Men and Dinosaurs: The Search in Field and Laboratory* (1968, reissued 1971), provides a thorough illustrated history of the discovery, collection, and study of dinosaurs. JOHN R. HORNER and JAMES GORMAN, *Digging Dinosaurs* (1988, reprinted 1995), is a fascinating account of the search for and collecting of dinosaur eggs and nests as told by the discoverers. JOHN H. OSTROM and JOHN S. MCINTOSH, *Marsh's Dinosaurs: The Collections from Como Bluff* (1966, reissued 1999), is illustrated for technical professionals and contains a historical study of one of the most famous dinosaur localities. For specific information about the origin of birds from theropod dinosaurs, LOWELL DINGUS and TIMOTHY ROWE, *The Mistaken Extinction: Dinosaur Evolution and the Origin of Birds* (1998), is an excellent reference source.

Natural history. JOHN R. HORNER and EDWIN DOBB, *Dinosaur Lives: Unearthing an Evolutionary Saga* (1997), explores developments in the understanding of dinosaurian paleobiology. PETER DODSON, *The Horned Dinosaurs: A Natural History* (1996), presents a case history of the ceratopsians, an important group of dinosaurs. KENNETH CARPENTER, KARL F. HIRSCH, and JOHN R. HORNER (eds.), *Dinosaur Eggs and Babies* (1994, reissued 1996), a technical multiauthor work, reviews many aspects of dinosaur reproductive biology.

Extinction. The most authoritative account of the Late Cretaceous extinctions is J. DAVID ARCHIBALD, *Dinosaur Extinction and the End of an Era: What the Fossils Say* (1996), a masterful book. WALTER ALVAREZ, *T. rex and the Crater of Doom* (1998), offers a somewhat different point of view. (J.H.O./K.P.)

Diplomacy

Diplomacy is the established method of influencing the decisions and behaviour of foreign governments and peoples through dialogue, negotiation, and other measures short of war or violence. Modern diplomatic practices are a product of the post-Renaissance European state system. Historically, diplomacy meant the conduct of official (usually bilateral) relations between sovereign states. By the 20th century, however, the diplomatic practices pioneered in Europe had been adopted throughout the world, and diplomacy had expanded to cover summit meetings and other international conferences, parliamentary diplomacy, the international activities of supranational and subnational entities, unofficial diplomacy by nongovernmental elements, and the work of international civil servants.

The term diplomacy is derived via French from the ancient Greek *diplōma*, composed of *diplo*, meaning "folded in two," and the suffix *-ma*, meaning "an object." The folded document conferred a privilege—often a permit to travel—and the term came to denote documents through which princes granted such favours. Later it applied to all solemn documents issued by chancelleries, especially those containing agreements between sovereigns. Diplomacy later became identified with international relations, and the direct tie to documents lapsed (except in diplomatics, which is the science of authenticating old official documents). In the 18th century, the French term *diplomate* ("diplomat" or "diplomatist") came to refer to a person authorized to negotiate on behalf of a state.

The purpose of diplomacy is to strengthen the state, nation, or organization it serves in relation to others by advancing the interests in its charge. To this end, diplomatic activity endeavours to maximize a group's advantages without the risk and expense of using force and preferably without causing resentment. It habitually, but not invariably, strives to preserve peace; diplomacy is strongly inclined toward negotiation to achieve agreements and resolve issues between states. Diplomacy normally seeks to develop goodwill toward the state it represents, nurturing relations with foreign states and peoples that will ensure their cooperation or—failing that—their neutrality. Even in times of peace, however, diplomacy may involve coercive threats of economic or other punitive measures or demonstrations of the capability to impose unilateral solutions to disputes by the application of military power. When diplomacy fails, war may ensue. Nevertheless, diplomacy is useful even during war. It conducts the passages from protest to menace, dialogue to negotiation, ultimatum to reprisal, and war to peace and reconciliation with other states.

This article discusses the history of diplomacy and the ways in which modern diplomacy is conducted. For a discussion of the legal rules governing diplomatic negotiation and the preparation of treaties and other agreements, see INTERNATIONAL LAW. The United Nations, one venue for diplomacy, is considered in detail in UNITED NATIONS. Foreign policy and diplomatic history in the 20th century is discussed in INTERNATIONAL RELATIONS, 20TH-CENTURY.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 544, and the *Index*.

The article is divided into the following sections:

HISTORY OF DIPLOMACY

The ancient world. Some elements of diplomacy predate recorded history. Early societies had some attributes of states, and the first international law arose from intertribal relations. Tribes negotiated about marriages and regulations on trade and hunting. Messengers and envoys were accredited, sacred, and inviolable; they usually carried some emblem, such as a message stick, and were received with elaborate ceremonies. Women often were used as envoys because of their perceived mysterious sanctity and their use of "sexual wiles"; it is believed that women regularly were entrusted with the vitally important task of negotiating peace in primitive cultures.

Egyptian diplomacy

Information regarding the diplomacy of early peoples is based on sparse evidence. There are traces of Egyptian diplomacy dating to the 14th century BC, but none has been found in western Africa before the 9th century AD. The inscriptions on the walls of abandoned Mayan cities indicate that exchanges of envoys were frequent, though almost nothing is known of the substance or style of Mayan and other pre-Columbian Central American diplomacy. In South America the dispatch of envoys by the expanding Incan Empire appears to have been a prelude to conquest rather than an exercise in bargaining between sovereigns.

Our greatest knowledge of early diplomacy concerns eastern West Asian and Mediterranean peoples, the ancient Chinese, and the Indians. Records of treaties between Mesopotamian city-states date from about 2850 BC. Thereafter, Akkadian (Babylonian) became the first diplomatic language, serving as the international tongue of the Middle East until it was replaced by Aramaic. A diplomatic correspondence from the 14th century BC existed between the Egyptian court and a Hittite king on cuneiform tablets in Akkadian—the language of neither. The oldest treaties of which full texts survive, from about 1280 BC, were between Ramses II of Egypt and Hittite leaders. There is significant evidence of Assyrian diplomacy in the 7th century and of the relations of Jewish tribes, found chiefly in the Bible, with each other and other peoples.

China. The first records of Chinese and Indian diplomacy date from the 1st millennium BC. By the 8th century BC, the Chinese had leagues, missions, and an organized system of polite discourse between their many "warring states." The Chinese tradition was very sophisticated, emphasizing the practical virtues of ethical behaviour in relations between states, and is well documented in the Chinese classics. The Chinese tradition of equal diplomatic dealings between contending states within China was ended by the country's unification under the Qin emperor in 221 BC and the consolidation of unity under the Han dynasty in 206 BC. Under the Han and succeeding dynasties, China emerged as the largest, most populous, technologically most advanced, and best-governed society in the world. The arguments of earlier Chinese philosophers, such as Mencius, prevailed; the best way for a state to exercise influence abroad, they had said, was to develop a moral society worthy of emulation by admiring foreigners and to wait confidently for them to come to China to learn.

Once each succeeding Chinese dynasty consolidated its rule at home and established its borders with the non-Chinese world, its foreign relations were typically limited to the defense of China's borders against foreign attacks or incursions, the reception of emissaries from neighbouring states seeking to ingratiate themselves and to trade with the Chinese state, and the control of foreign merchants in specific ports designated for foreign trade. With rare exceptions, Chinese leaders and diplomats waited at home for foreigners to pay their respects rather than venturing abroad themselves. This "tributary system" lasted until European colonialism overwhelmed it and introduced to Asia the European concepts of sovereignty, suzerainty, spheres of influence, and other diplomatic norms, traditions, and practices.

India. Ancient India also possessed an equally sophisticated but very different diplomatic tradition, which was systematized and described in the Artha-śāstra by the scholar-statesman Kautilya at the end of the 4th century BC. The ruthlessly realistic state system codified in the Artha-śāstra insisted that foreign relations be determined by self-interest rather than by ethical considerations. It graded state power with respect to five factors and emphasized espionage, diplomatic maneuver, and contention by 12 categories of states within a complex geopolitical matrix. It also posited four expedients of statecraft (conciliation, seduction, subversion, and coercion) and six forms of state policy (peace, war, nonalignment, alliances, shows of force, and double-dealing). To execute policies derived from these strategic geometries, ancient India fielded three categories of diplomats (plenipotentiaries, envoys entrusted with a single issue or mission, and royal messengers); a type of consular agent, who was charged with managing commercial relations and transactions; and two kinds of spies (those charged with the collection of intelligence and those entrusted with subversion and other forms of covert action).

The Artha-śāstra

The Indian state, which was separated from its neighbours by deserts, seas, and the Himalayas, had little political connection to other regions of the world until Alexander the Great conquered its northern regions in 326 BC. The establishment of the native Mauryan empire ushered in a new era in Indian diplomatic history that attempted to extend both Indian religious doctrines and political influence beyond South Asia. The Mauryan emperor Aśoka was particularly active, receiving several emissaries from the Macedonian-ruled kingdoms and dispatching numerous Brahman-led missions of his own to West, Central, and Southeast Asia. Such contacts continued for centuries until the ascendancy of the Rājput kingdoms (8th to the 13th century AD) again isolated northern India from the rest of the world. Outside the Cōḷa dynasty and other Dravidian kingdoms of South India, India's distinctive mode of diplomatic reasoning and early traditions were forgotten and replaced by its Muslim and British conquerors.

Greece. The tradition that ultimately inspired the birth of modern diplomacy in post-Renaissance Europe and that led to the present world system of international relations began in ancient Greece. Some of the first traces of interstate relations concern the Olympic Games of 776 BC. In the 6th century BC, the amphictyonic leagues maintained interstate assemblies with extraterritorial rights and permanent secretariats. Sparta was actively forming alliances in the mid-6th century BC, and by 500 BC it had created

Amphictyonic leagues

the Peloponnesian League. In the 5th century BC, Athens led the Delian League during the Greco-Persian Wars.

Greek diplomacy took many forms. Heralds, references to whom can be found in prehistory, were the first diplomats and were protected by the gods with an immunity that other envoys lacked. Because heralds were inviolable, they were the favoured channels of contact in wartime, preceding envoys to arrange for safe passage. Whereas heralds traveled alone, envoys journeyed in small groups, to ensure each other's loyalty. Because they were expected to sway foreign assemblies, envoys were chosen for their oratorical skills. Unlike modern ambassadors, heralds and envoys were short-term visitors in the city-states whose policies they sought to influence.

In marked contrast to diplomatic relations, commercial and other apolitical relations between city-states were conducted on a continuous basis. Greek consular agents, or *proxeni*, were citizens of the city in which they resided, not of the city-state that employed them. Like envoys, they had a secondary task of gathering information, but their primary responsibility was trade.

The Greeks developed archives, a diplomatic vocabulary, principles of international conduct that anticipated international law, and many other elements of modern diplomacy. Their envoys and entourages enjoyed diplomatic immunity for their official correspondence and personal property. Truces, neutrality, commercial conventions, conferences, treaties, and alliances were common. In one 25-year period of the 4th century BC, for example, there were eight Greco-Persian congresses, where even the smallest states had the right to be heard.

Rome. Rome inherited what the Greeks devised and adapted it to the task of imperial administration. As Rome expanded, it often negotiated with representatives of conquered areas, to which it granted partial self-government by way of a treaty. Treaties were made with other states under Greek international law. During Rome's dominance, envoys were received with ceremony and magnificence, and they and their aides were granted immunity.

Roman envoys were sent abroad with written instructions from their government. Sometimes a messenger, or *nuntius*, was sent, usually to towns. For larger responsibilities, a *legatio* ("embassy") of 10 or 12 *legati* ("ambassadors") was organized under a president. The *legati*, who were leading citizens chosen for their skill at oratory, were inviolable. Rome also created sophisticated archives, which were staffed by trained archivists. Paleographic techniques were developed to decipher and authenticate ancient documents.

Roman law became the basis of treaties. Late in the Republican era, the laws applied by the Romans to foreigners and to foreign envoys were merged with the Greek concept of natural law to create a "law of nations." The sanctity of treaties and the law of nations were absorbed by the Roman Catholic church and preserved in the centuries after the Western Roman Empire collapsed in the 5th century AD.

Even as monarchs negotiated directly with nearby rulers or at a distance through envoys from the 5th through the 9th century, the papacy continued to use *legati*. Both forms of diplomacy intensified in the next three centuries. Moreover, the eastern half of the Roman Empire continued for nearly 1,000 years as the Byzantine Empire. Its court at Constantinople, to which the papacy sent envoys from the mid-5th century, had a department of foreign affairs and a bureau to deal with foreign envoys. Aiming to awe and intimidate foreign envoys, Byzantium's rulers marked the arrival of diplomats with spectacular ceremonies calculated to suggest greater power than the empire actually possessed.

Islāmic diplomacy

The Middle Ages. *Islām.* Inspired by their religious faith, followers of Islām in Arabia conquered significant territory beginning in the 7th century, first by taking Byzantium's southern and North African provinces and then by uniting Arabs, Persians, and ultimately Turks and other Central Asian peoples in centuries of occasionally bloody conflict with the Christian Byzantines. Islāmic diplomatic missions, both to other Muslim states and to non-Muslim states, existed from the time of Muḥammad, and early Islāmic rulers and jurists developed an elaborate set of protections and rules to facilitate the exchange of emissaries. As Muslims came to dominate vast territories in Africa, Asia, and Europe, the experience of contention with Byzantium shaped Islāmic diplomatic tradition along Byzantine lines.

Byzantium. Byzantium produced the first professional diplomats, who were issued written instructions and were enjoined to be polite and to encourage trade. From the 12th century, their role as gatherers of information about conditions in their host states became increasingly vital to the survival of the Byzantine state. As its strength waned, timely intelligence from Byzantine diplomats enabled the emperors to play off foreign countries against each other. Byzantium's use of diplomats as licensed spies and its employment of the information they gathered to devise skillful and subtle policies to compensate for a lack of real power inspired many governments. After the Byzantine Empire's collapse in 1453, major elements of its diplomatic tradition lived on in the Ottoman Empire and in Renaissance Italy.

The Roman Catholic church. As Byzantium crumbled, the West revived. Indeed, even in its period of greatest weakness, the Roman Catholic church conducted an active diplomacy, especially at Constantinople and in its 13th-century struggle against the Holy Roman emperors. Popes served as arbiters, and papal legates served as peacemakers. The prestige of the church was such that, at every court, papal emissaries took precedence over secular envoys, a tradition that continues in countries where Roman Catholicism is the official religion. The Roman emphasis on the sanctity of legates became part of canon law, and church lawyers developed increasingly elaborate rules governing the status, privileges, and conduct of papal envoys, rules that were adapted later for secular use.

Papal diplomacy

From the 6th century, both legates and (lesser-ranking) *nuncii* ("messengers") carried letters of credence to assure the rulers to whom they were accredited of the extent of their authority as agents of the pope, a practice later adopted for lay envoys. A *nuncius* was a messenger who represented and acted legally for the pope; *nuncii* could negotiate draft agreements but could not commit the pope without referral. In time, the terms legate and *nuncius* came to be used for the diplomatic representatives of both secular rulers and the pope. By the 12th century, the secular use of *nuncii* as diplomatic agents was commonplace.

When diplomacy was confined to nearby states and meetings of rulers were easily arranged, a visiting messenger like the *nuncius* sufficed. As trade revived, however, negotiations at a distance became increasingly common. Envoys no longer could refer the details of negotiations to their masters on a timely basis. They therefore needed discretionary authority to decide matters on their own. To meet this need, in the 12th century the concept of a procurator with *plena potens* ("full powers") was revived from Roman civil law. This plenipotentiary could negotiate and conclude an agreement, but, unlike a *nuncius*, he could not represent his principal ceremonially. As a result, one emissary was often given both offices.

At the end of the 12th century, the term ambassador appeared, initially in Italy. Derived from the medieval Latin *ambactiare*, meaning "to go on a mission," the term was used to describe various envoys, some of whom were not agents of sovereigns. Common in both Italy and France in the 13th century, it first appeared in English in 1374 in *Troilus and Criseyde* by Geoffrey Chaucer. By the late 15th century, the envoys of secular rulers were commonly called ambassadors, though the papacy continued to send legates and *nuncii*.

The Crusades and the revival of trade increased Europe's contact with the eastern Mediterranean and West Asia. Venice's location provided it with early ties with Constantinople, from which it absorbed major elements of the Byzantine diplomatic system. Venice gave its envoys written instructions and established a systematic archive. Later it developed an extensive diplomacy on the Byzantine model, which emphasized the reporting of conditions in the host country. Initially, returning Venetian envoys presented their *relazione* ("final report") orally, but they

began in the 15th century to present such reports in writing. Other Italian city-states, then France and Spain, copied Venetian diplomatic methods and style.

The Renaissance to 1815. It is unclear which Italian city-state had the first permanent envoy. In the late Middle Ages and the early Renaissance, most embassies were temporary. As early as the late 14th and early 15th centuries, however, Venice, Milan, and Mantua sent resident envoys to each other, to the popes, and to the Holy Roman emperors. Resident embassies became the norm in Italy in the late 15th century, and after 1500 the practice spread northward. A permanent Milanese envoy to the French court of Louis XI arrived in 1463 and was later joined by a Venetian representative. Ambassadors served a variety of roles, including reporting events back home and negotiating with their hosts. In addition, they absorbed the role of commercial consuls, who were not then diplomatic agents.

Growth of resident embassies

Italy's economic revival, geographic location, and small size fostered the creation of a European state system in microcosm. Because the peninsula was fully organized into states, wars were frequent, and the maintenance of a balance of power necessitated constant diplomatic interaction. Whereas meetings of rulers were considered risky, unobtrusive diplomacy by resident envoys was deemed safer and more effective. Thus, the system of permanent agents took root.

Rome became the centre of Italian diplomacy and of intrigue, information gathering, and spying. Popes received ambassadors but did not send them. The papal court had the first organized diplomatic corps: the popes addressed the envoys jointly, seated them as a group for ceremonies, and established rules for their collective governance.

As resident missions became the norm, ceremonial and social occasions came to dominate the relations between diplomats and their hosts. Papal envoys took precedence over those of temporal rulers. Beyond this, there was little agreement, and there was frequent strife. Pope Julius II established a list of precedence in 1504, but it did not solve the problem. Spain did not accept inferiority to France, power fluctuated among the states, papal power declined, and the Protestant Reformation complicated matters—not least regarding the pope's own position. By the 16th century, the title of ambassador was being used only for envoys of crowned heads and the republic of Venice. Latin remained the international language of diplomacy.

The French invasion of Italy in 1494 confronted the Italian states with a power greater than any within their own state system. They were driven to substitute subtle diplomacy and expedient, if short-lived, compromise for the force they lacked. This tendency, plus their enthusiasm for diplomatic nuances and for the 16th-century writings of Niccolò Machiavelli, gave Italian diplomacy a reputation for deviousness. But it was no more so than that of other states, and Machiavelli, himself a diplomat, argued that an envoy needed integrity, reliability, and honesty—views seconded since by virtually every authority.

The 16th-century wars in Italy, the emergence of strong states north of the Alps, and the Protestant Reformation ended the Italian Renaissance but spread the Italian system of diplomacy. Henry VII of England adopted the Italian diplomatic system, and initially he even used Italian envoys. By the 1520s, Thomas Cardinal Wolsey, Henry VIII's chancellor, had created an English diplomatic service. France adopted the Italian system in the 1520s and had a corps of resident envoys by the 1530s.

Because they were highly trusted as personal emissaries of one ruler to another, and because communications were slow, ambassadors enjoyed considerable freedom of action. Their task was complicated by the ongoing religious wars, which generated distrust, narrowed contacts, and jeopardized the reporting that was essential before newspapers were widespread.

The religious wars of the early 17th century were an Austro-French power struggle. During the Thirty Years' War, innovations occurred in the theory and practice of international relations. In 1625 the Dutch jurist Hugo Grotius published *De Jure Belli ac Pacis* (*On the Law of War and Peace*), in which the laws of war were most numerous. In an effort to convert the law of nations into a law among nations and to provide it with a new secular rationale acceptable to both sides in the religious quarrel, Grotius fell back on the classical view of natural law and the rule of reason. He also enunciated the concepts of state sovereignty and the equality of sovereign states.

Grotius' *Law of War and Peace*

The first modern foreign ministry was established in 1626 in France by Armand-Jean du Plessis Cardinal Richelieu. He created the Ministry of External Affairs to centralize policy and to ensure his control of envoys as he pursued the *raison d'état* ("national interest"). Richelieu rejected the view that policy should be based on dynastic or sentimental concerns or a ruler's wishes, holding instead that the state transcended crown and land, prince and people, having interests and needs independent of all these elements. He asserted that the art of government lay in recognizing these interests and acting according to them, regardless of ethical or religious considerations.

Richelieu's practices led him to ally Roman Catholic France with the Protestant powers in the Thirty Years' War against France's great rival, Austria. He largely succeeded, for the Peace of Westphalia of 1648 weakened Austria and enhanced French power. The four years of meetings before its signature were the first great international congresses of modern history. Princes attended, but diplomats did most of the work in secret meetings. The task of the diplomats was complicated by the need for two simultaneous congresses, because the problem of precedence was otherwise insoluble.

The Treaty of Westphalia did not solve precedence disputes. The war between France and Spain, which continued from 1648 to 1659, was partly about this issue. Shortly thereafter, in 1661, there was a diplomatic dispute in London concerning whether the French ambassador's carriage would precede that of his Spanish rival. War was narrowly averted, but questions of precedence continued to bedevil European diplomacy.

During Louis XIV's reign, aristocratic envoys became common, not least because of the expense involved. As a result of Louis XIV's preeminence, French superseded Latin as the language of diplomacy and continued as the lingua franca of diplomacy until the 20th century.

Diplomacy of Louis XIV

Louis XIV personally directed French foreign policy and read the dispatches of his ambassadors himself. The foreign minister belonged to the Council of State and directed a small ministry and a sizable diplomatic corps under the king's supervision. Envoys were assigned for three or four years and given letters of credence, instructions, and ciphers for secret correspondence. Louis XIV's frequent wars resulted at their conclusion in peace congresses, which were attended by diplomats.

Some states regularized the position of consuls as state officials, though they were not considered diplomats. The French system was imitated by other major states in the 18th century. The ambassadors they sent forth were true plenipotentiaries, able to conclude treaties on their own authority. The title of ambassador was used only for the envoys of kings (and for those from Venice). The diplomacy of the time recognized the existence of great powers by according special rank and responsibility to the representatives of these countries. New among these was Russia, whose diplomatic tradition married elements derived directly from Byzantium to the now essentially mature diplomatic system that had arisen in western Europe.

At the century's end, a power of second rank appeared outside Europe: the United States. The founders of American diplomacy (*e.g.*, Benjamin Franklin and Thomas Jefferson) accepted the norms of European diplomacy but declined to wear court dress or to adopt usages they considered unrepublican. To this day, American ambassadors, unlike those of other countries, are addressed not as "Your Excellency" but simply as "Mr. Ambassador."

The Concert of Europe to World War I. *The Concert and the balance of power.* In the 18th century, European diplomacy strove to maintain a balance between Britain, France, Austria, Russia, and Prussia. At the century's end, however, the French Revolution and the attempts of Napoleon I to conquer Europe first unbalanced and then overthrew the continent's state system. After Napoleon's defeat, the Congress of Vienna was convened in 1814–15

The Congress of Vienna

to set new boundaries, re-create the balance of power, and guard against future French hegemony. The Final Act of Vienna of 1815, as amended at the Congress of Aix-la-Chapelle (Aachen) in 1818, established four classes of heads of diplomatic missions—precedence within each class being determined by the date of presentation of credentials—and a system for signing treaties in French alphabetical order by country name. Thus ended the battles over precedence. Unwritten rules also were established. At Vienna, for example, a distinction was made between great powers and "powers with limited interests." Only great powers exchanged ambassadors. Until 1893 the United States had no ambassadors; like other lesser states, its envoys were only ministers.

More unwritten rules were soon developed. Napoleon's return and second defeat required a new peace treaty with France at Paris in November 1815. On that occasion, the four great victors (Britain, Austria, Russia, and Prussia) formally signed the Quadruple Alliance, which called for periodic meetings of the signatories to consult on common interests, to ensure the "repose and prosperity of the Nations," and to maintain the peace of Europe. This clause, which created a Concert of Europe, entailed cooperation and restraint, as well as a tacit code: the great powers would make all important decisions; internal changes in any member of the Concert had to be sanctioned by the great powers; the great powers were not to challenge each other; and the Concert would decide all disputes. The Concert thus constituted a rudimentary system of international governance by a consortium of great powers.

Initially, meetings of the Concert were attended by rulers, chancellors, and foreign ministers. The first meeting (1818) resulted in the admittance of France to the Concert and the secret renewal of the Quadruple Alliance against it. It was the first international congress held in peacetime and the first to attract coverage by the press. Thus was born the public relations aspect of diplomacy and the press communiqué.

Thereafter, congresses met in response to crises. Owing to disputes between the powers, after 1822 the meetings ceased, though the Concert itself continued unobtrusively. Beginning in 1816 an ambassadorial conference was established in Paris to address issues arising from the 1815 treaty with France. Other conferences of ambassadors followed to address specific international problems and to sanction change when it seemed advisable or unavoidable. The Concert was stretched and then disregarded altogether between 1854 and 1870, during the Crimean War and the unifications of Italy and Germany. The century during which it existed (1815–1914) was generally peaceful, marred only by short, limited wars.

Conference diplomacy and the effects of democratization. After three decades, Europe reverted to conference diplomacy at the foreign-ministerial level. The Congress of Paris of 1856 not only ended the Crimean War but also resulted in the codification of a significant amount of international law. As European powers extended their sway throughout the world, colonies and spheres of influence in areas remote from Europe came increasingly to preoccupy their diplomacy. Conferences in Berlin in 1878 and 1884–85 prevented conflagrations over the so-called "Eastern" and "African" questions—euphemisms, respectively, for intervention on behalf of Christian interests in the decaying Ottoman Empire and the carving up of Africa into European-ruled colonies. Furthermore, multilateral diplomacy was institutionalized in a permanent form. The peace conferences at The Hague (1899–1907), which resulted in conventions aimed at codifying the laws of war and encouraging disarmament, were harbingers of the future.

The Hague peace conferences

During the 19th century the world underwent a series of political transformations, and diplomacy changed with it. In Europe, power shifted from royal courts to cabinets. Kings were replaced by ministers at international meetings, and foreign policy became a matter of increasingly democratized politics. With mass literacy and the advent of inexpensive newspapers, foreign policy came to be swayed by public opinion.

The spread of European diplomatic norms. Meanwhile, European culture and its diplomatic norms spread throughout the world. Most Latin American colonies became independent, and they adopted the existing system without question. The British Empire then united all of the subcontinent for the first time under a single sovereignty. In the mid-19th century, an American naval flotilla forced Japan to open its society to the rest of the world. Afterward, Japan embarked on a rapid program of modernization based on the wholesale adoption of Western norms of political and economic behaviour.

In the late 18th and early 19th centuries, European emissaries to China faced demands to prostrate themselves ("kowtow") to the Chinese emperor in order to be formally received by him in Beijing (Peking), a humiliating practice not encountered since the era of Byzantium. As plenipotentiary representatives of foreign sovereigns, they viewed it as completely inconsistent with the Westphalian concept of sovereign equality. The Chinese, for their part, neither understood nor accepted European diplomatic concepts and practices and were vexed and insulted by the unwillingness of Western representatives to respect the long-established ceremonial requirements of the Chinese court. In the ensuing argument over diplomatic protocol, Europeans prevailed by force of arms. In 1860 British and French forces sacked and pillaged the emperor's summer palace and some areas around Beijing. They refused to withdraw until the Chinese court had agreed to receive ambassadors on terms consistent with Western practices and to make other concessions.

Western diplomacy beyond Europe initially was conducted at a leisurely pace, given the vastly greater distances and times required for communication. Fortunately, the dispatch of far-flung legations developed almost simultaneously with advances in transportation and communications, which made frequent contact possible. The railway, the telegraph, the steamship, and undersea cable sped the transmittal of instructions and information. Improvements in technology now made referral to the capital possible and ensured that capitals heard from their envoys abroad, even in the most distant places, on a more frequent and timely basis.

Speedier communication, more involvement in commercial diplomacy as trade became crucial to prosperity, and, especially, the advent of typewriters and mimeograph machines all contributed to a significant increase in the number of diplomatic reports. Yet diplomacy remained a relatively gilded and leisurely profession. It also remained a relatively small one. Before 1914 there were 14 missions in Washington, D.C.; by the beginning of the 21st century, the number of missions had increased by more than 12-fold. Diplomats shared a similar education, ideology, and culture. They saw themselves as an elite and carefully upheld the fiction that they still were personal envoys of one monarch to another.

The 1920s to the 1980s. *The League of Nations and the revival of conference diplomacy.* Despite its risks and inherent complexity, conference diplomacy was revived during World War I and continued afterward, especially during the 1920s. The Paris Peace Conference took place amid much publicity, which was intensified by the newsreels made of the event. U.S. President Woodrow Wilson had enunciated his peace program in January 1918, including "open covenants of peace openly arrived at" as a major goal of diplomacy in the post-World War I period. His phrasemaking, which entangled process and result, caused confusion. Hundreds of journalists went to the conference only to discover that all but the plenary sessions were closed. Wilson had intended that the results of diplomatic negotiations be made public, with treaties published and approved by legislatures. He largely achieved this goal, as the Covenant of the League of Nations required that treaties be registered at the League before they became binding.

The Paris conference and later conferences were conducted in both English and French. As at Vienna, political leaders attended, but kings and princes were strikingly absent. Even more strenuously than at Vienna, nongovernmental organizations, most representing national entities seeking independence, sought a hearing at the court of the great powers. Ultimately, some European peoples gained

independence, which resulted in a dramatic increase in the number of sovereign states.

The League of Nations

The chief innovation of the peace negotiations was the creation of the League of Nations as the first permanent major international organization, with a secretariat of international civil servants. The League introduced parliamentary diplomacy in a two-chamber body, acknowledging the equality of states in its lower house and the supremacy of great powers in its upper one. As neither chamber had much power, however, the sovereignty of members was not infringed. The League of Nations sponsored conferences and supervised specialized agencies, some of which were newly created.

Despite the presence of a Latin American bloc and a few independent or quasi-independent states of Africa and Asia, the League of Nations was primarily a European club. Diplomats became orators again in the halls of Geneva, but the topics were often trivial. Decisions taken in public were rehearsed in secret sessions. On important matters, foreign ministers attending League councils met privately. In 1923 the League revealed its impotence by dodging action in the Corfu crisis, in which Italian troops occupied the Greek island following the murder of an Italian general on Greek soil. In later years the League failed to improve its record on international crises.

The weakness of the League of Nations was aggravated by the absence of the United States, whose Senate refused to ratify the peace treaties by which the League was created. The Senate's inaction raised questions about the country's reliability—the basis of effective diplomacy—and drew attention to the blurring of the line between foreign and domestic policy and, in the view of some, the irresponsibility of democratic electorates. It also rendered good diplomacy—which is based on compromise, mutual advantage, and lasting interests—extremely difficult.

In Europe, where electorates were constantly preoccupied with foreign policy, this problem was most acute. Statesmen, trailed by the popular press, engaged in personal diplomacy at frequent conferences. Foreign offices, diplomats, and quiet negotiation were eclipsed as prime ministers and their staffs executed policy in a blaze of publicity. Governments manipulated this publicity to influence public opinion in favour of their policies. As the masses became concerned with such matters, unprecedented steps were taken to bribe the foreign press, to plant stories, and to use public occasions for propaganda speeches aimed at foreign audiences.

Despite these changes, the "new diplomacy" of the early 20th century was not so new. The negotiating process remained the same. Talks continued to be held in secret, and usually only their results were announced to the public. Meanwhile, diplomats deplored the decline of elite influence and the effects of expanded democracy—*e.g.*, press scrutiny, public attention, and the involvement of politicians—on the diplomatic process.

The tensions of the 1930s revived conference diplomacy, which continued during World War II. Thereafter, summit meetings between heads of government became the norm as technology again quickened the tempo of diplomacy. In the 1930s, statesmen began to telephone each other, a practice that was epitomized in the 1960s by the Soviet-American "hot line." Similarly, the flights of British Prime Minister Neville Chamberlain to Germany in 1938, resulting in the Munich agreement that allowed Germany to annex the Sudetenland in western Czechoslovakia, started a trend in diplomacy. With airplanes at their disposal, leaders met often in the postwar world. As Kojo Debrah, a Ghanaian diplomat, later remarked, "Radio enables people to hear all evil, television enables them to see all evil, and the jet plane enables them to go off and do all evil."

The rise of totalitarian regimes. World War I accelerated many changes in diplomacy. The Russian Revolution of 1917 produced a powerful new regime that rejected the political assumptions and practices of the Western world and used political language—including the terms democracy, propaganda, and subversion—in new ways.

Soviet diplomacy

The communist government of the Soviet Union abolished diplomatic ranks and published the secret treaties it found in the czarist archives. Without delay, the People's Commissariat of Foreign Affairs (known by its Russian acronym, the Narkomindel) organized a press bureau and a bureau for international revolutionary propaganda. As Russia entered peace negotiations with Germany, it substituted propaganda for the power it lacked, appealing openly to the urban workers of other states to exert pressure on their governments. Under the leadership of Joseph Stalin, the Soviet Union used each concession it won as a basis to press for another, and it viewed diplomacy as war, not as a process of mutual compromise. Nazi Germany was equally indifferent to accommodation and Western opinion once it achieved rearmament; Adolf Hitler signed treaties with the intention of keeping them only as long as the terms suited him, regarded with contempt those who accommodated him, and cowed foreign leaders with tantrums and threats.

Diplomacy during the Cold War. After World War II, most of the world divided into two tight blocs, one dominated by the United States and one by the Soviet Union. The Cold War took place under the threat of nuclear catastrophe and gave rise to two major alliances—the North Atlantic Treaty Organization, led by the United States, and the Warsaw Pact, led by the Soviet Union—a conventional and nuclear arms race, endless disarmament negotiations, much conference diplomacy, many summits, and periodic crisis management, a form of negotiation aimed at living with a problem, not solving it. As a result, a premium was placed on the diplomatic art of continuing to talk until a crisis ceased to boil. The widening Cold War entailed more espionage, of which ambassadors were officially ignorant; thus, large embassies appeared in small but strategic countries. Propaganda and so-called "cultural diplomacy"—as typified by the international tours of Russian dance companies and the cultural programs of the Alliance Française, the British Council, and various American libraries—expanded as well. Cold War competition also extended to international arms transfers. Gifts or sales of weapons and military training were a means of influencing foreign armed forces and consolidating relationships with key elements of foreign governments. The increasing complexity and expense of modern weapons also made military exports essential for preserving industrial capacity and employment in the arms industries of the major powers. Diplomats thus became arms merchants, selling weapons to their host governments.

The many diplomatic tasks reflected a world that was more fragmented and divided. This dangerous situation led to a search for mechanisms to manage the Cold War in order to prevent a nuclear holocaust. Neither the UN nor the Western policy of containment provided an answer. As the two blocs congealed, a balance of terror in the 1960s was followed by an era of détente in the 1970s and then by a return to deterrence in the 1980s. But the 45 years of Cold War did not produce an organizing principle of any duration. Great-power conflict was conducted by proxy through client states in developing areas.

Diplomats as targets

As old diplomatic premises broke down, diplomacy became a hazardous career. Diplomats were targeted because they represented states and symbolized privileged elites. Security precautions at embassies were increased (some came to resemble fortresses) but were insufficient if host governments turned a blind eye to breaches of extraterritoriality. Attacks on diplomatic missions and diplomats grew, with terrorists succeeding in taking the staffs of some diplomatic missions hostage and in blowing up others.

Some new states also adopted the Soviet tactic of offensive behaviour as a tool of policy, appealing, over the heads of government, to the common people in the opponent's camp. It tried to discredit governments by accusing them of ugly motives, and it sometimes trumpeted maximum demands in calculatedly offensive language as conditions for negotiation. Public diplomacy of this ilk was often noisy, bellicose, and self-righteous.

As diplomacy raised its voice in public, propaganda, abetted by technology, became a key tool. Radio Free Europe and the Voice of America broadcast one message to the communist bloc; proselytizing Christian churches and so-called "national liberation movements" used transistor ra-

dios to spread their messages to other areas. Television also became crucial, as its images provided an immediacy that words alone could not convey. Mass demonstrations were staged for the benefit of television and featured banners in English, which had become the dominant international language. When the United States invaded Panama in 1989, the Soviet Union protested on the American-owned television company Cable News Network, which was watched by most world leaders.

The effects of decolonization. World War II also sounded the death knell for global empires. The immediate postwar period saw the reemergence into full independence of several great civilizations that the age of imperialism had placed under generations of European tutelage. Many of these reborn countries adopted with zeal the central doctrines of European diplomacy, including the concepts of sovereignty, territorial integrity, and noninterference in internal affairs.

After a long struggle for independence, Indians formed two proudly assertive but mutually antagonistic states, India and Pakistan. China's century-long humiliation at the hands of the West exploded in a series of violent revolutions seeking to restore the country to wealth, power, and a place of dignity internationally. "Two Chinas" were eventually established, one communist and the other backed by the United States (Taiwan), the latter of which for two decades spoke for China in the United Nations. The question of China's international representation became one of the great diplomatic issues of the 1950s and '60s. The countries of the Arab world resumed their independence and then insisted, over the objections of their former colonial masters, on exercising full sovereignty throughout their own territories, as Egypt did with respect to the Suez Canal. Anti-imperialist sentiment soon made colonialism unacceptable. By the late 1950s and '60s, new states, mainly in Africa, were being established on an almost monthly basis.

The new states shared the diplomatic forms of the industrialized democracies of the West but not their political culture. Many new states were ill at ease with the values of their former colonial masters and cast about for alternatives drawn from their own history and national experience. Others accepted Western norms but castigated the West for hypocrisy. Envoys began to appear in Western capitals dressed in indigenous regalia to symbolize their assertion of ancient non-Western cultural identities. As they gained a majority at the UN, the newly independent states altered the organization's stance toward colonies, racial issues, and indigenous peoples. Beyond the East-West division of the Cold War, there developed a "North-South" divide between the wealthier former imperial powers of the north and their less-developed former colonies.

The United Nations

The UN, founded in 1946 with only 51 members, was no more successful at healing the North-South rift than it was at healing the East-West one. It was, according to former Indian permanent representative Arthur Lall, "a forum and not a force." On major questions and issues, the UN played only a marginal role, though secretaries-general and their deputies made intense efforts to solve serious but secondary problems such as the resettlement of refugees and persons displaced by war. In the end—as Dag Hammarskjöld, UN secretary-general from 1953 to 1961, remarked—the UN remained only "a complement to the normal diplomatic machinery" of the governments that were its members.

After the larger colonies gained independence, smaller ones followed suit. The new states were often economically underdeveloped and lacked a large educated elite to staff a modern diplomatic corps. The trend continued until even "microstates" of small area and population (*e.g.*, at its independence Nauru had a population under 7,000) became sovereign. The new small states were unable to conduct much diplomacy at first. Many of them accredited ambassadors to only the former colonial power, a key neighbouring state, and the UN.

Over time, the larger of the newly independent states built sizable foreign services modeled on that of the former colonial power or those of the similarly organized services of Brazil and India, which were not complicit in colonialism. The Brazilian foreign ministry and diplomatic service, which were organized and staffed along European lines, enjoyed a reputation as the most professional of such organizations in Latin America. The Indian Foreign Service, which was modeled on the highly respected Indian Administrative Service and initially staffed from its ranks, quickly emerged as a competent practitioner of diplomacy on behalf of a nonaligned, non-Western potential great power. In contrast, the microstates had few missions; instead, they experimented with joint representation, multiple accreditation of one envoy to several capitals, and meeting with foreign envoys in their own capitals. Some states had no foreign ministry and relied on regional powers to represent them.

The exponential growth in the number of states complicated diplomacy by requiring countries—especially the major powers—to staff many different diplomatic missions at once. As state, transnational, and quasi-diplomatic entities proliferated, so did the functions of diplomacy. Leaders met often, but as there was more for diplomats to do, the size of missions of major powers increased.

Regional and subnational organizations. Unlike the UN, some regional organizations achieved significant diplomatic successes. The European Union (EU) effectively promoted trade and cooperation with member states, and the Organization of African Unity (later the African Union) and the Arab League enhanced the international bargaining power of regional groupings of new states by providing a coherent foreign policy and diplomatic strategy. In contrast, the extreme political, economic, and cultural diversity of Asia made it harder to organize effectively; the Organization of American States suffered from the enormous imbalance between the United States and its smaller, poorer, and less-powerful members; and the nonaligned movement was too disparate for long-term cohesion.

Subnational entities also complicated the crowded international scene. Foremost among these was the Palestine Liberation Organization, which had observer status at the UN, membership in the Arab League, and envoys in most of the world's capitals, many with diplomatic status. The African National Congress and the South West Africa People's Organization also conducted long and varied diplomatic campaigns before achieving power in South Africa and Namibia, respectively.

New topics of diplomacy. New topics of diplomacy also abounded, including economic and military aid, commodity-price stabilization, aviation, and allocations of radio frequencies. Career diplomats tended to be generalists, and specialists increasingly came from other agencies as attachés or counselors. Disarmament negotiations, for example, required specialized knowledge beyond the scope of military attachés. Environmental abuse gave rise to a host of topics, such as the law of the sea, global warming, and means of preventing or abating pollution. The complexity of diplomatic missions increased accordingly. By the 1960s, for example, U.S. missions had instituted "country teams," including the ambassador and the heads of all attached missions, who met frequently to unify policy and reporting efforts and to prevent different elements under the ambassador from working at cross-purposes.

Diplomatic personnel and the role of women. In the 1970s the United States, Australia, and some other industrialized democracies (as well as South Africa) broadened recruitment beyond the old elites and attempted to develop foreign services representative of their populations' ethnic diversity. Others, such as Brazil, France, India, and Japan, continued to recruit self-consciously elite services. China and the Soviet Union continued to emphasize political criteria as well as intellectual skills. Overall, however, embassy positions, from the ambassadorial level down, increasingly were filled by professional diplomats. The United States and a handful of other countries, however, continued to appoint wealthy amateurs as ambassadors, treating the most senior diplomatic positions as political spoils.

Although famous female political leaders such as Cleopatra VII, Isabella I, and Elizabeth I were enormously influential in the history of diplomatic relations, historically women largely played a secondary—but substantial—role

as the wives of diplomats. Without large fortunes or many servants, diplomatic wives were forced to shoulder greater burdens as they coped with a nomadic lifestyle, housewifery, hectic social schedules, and endless cooking for obligatory entertaining. The strain became so severe that many ambassadors retired early. In response, Japan adopted the practice of paying diplomatic wives a salary to compensate them for the time they spent entertaining. In 1972 the United States stopped evaluating wives when rating their spouses; entertaining and attending functions were no longer required, though they were still expected. Diplomatic wives also increasingly wished to pursue their own careers. Some of these careers were portable, but when they were not, efforts were made with host countries to find suitable employment.

Women diplomats

In 1923 the Soviet Union became the first country to name a woman as head of a diplomatic mission. The United States, which admitted women to the diplomatic corps beginning in 1925, followed a decade later by appointing a woman as minister to Denmark. France permitted a woman to enter its diplomatic service in 1930, though it still did not appoint women as heads of mission.

After World War II, many women began diplomatic careers, and more women became ambassadors. However, some countries, particularly in the developing world, continued not to hire women as diplomats, and sending women envoys to them was deemed unwise. In 1970 the Vatican rejected a proposed minister from West Germany because she was female. With these exceptions, however, women became an accepted and rapidly growing minority in the diplomatic—including the ambassadorial—ranks. By the end of the 20th century, several American women were serving as ambassadors in Arab and Islāmic countries long considered inhospitable to women.

Before this trend began, women seemed to face almost insuperable difficulties in combining marriage with the nomadic career of diplomacy. Before 1971 the U.S. Foreign Service required women to resign upon marriage. Problems were particularly pronounced for "tandem couples," in which both husband and wife were in the Foreign Service. Because joint postings could not always be arranged, husband and wife often would alternate in taking leave when not posted in adjacent countries. Despite these problems, at the end of the 20th century the U.S. Foreign Service employed some 500 tandem couples.

The end of the Cold War. In 1989, when the Cold War sputtered to a close, there were more than 7,000 diplomatic missions worldwide, most of which were embassies and thus headed by ambassadors. Between World War I and World War II, a few lesser states had been allowed to accredit embassies, but when the United States elevated Latin American missions in the 1940s, a trickle became a flood. Soon legations were the exception, and they disappeared by the last quarter of the 20th century. In addition, numerous international organizations and an array of regional entities, some of them supranational, also now received and sent envoys of ambassadorial rank. For example, some states now accredit three ambassadors to Brussels: to the Belgian government, to the EU, and to NATO.

Meanwhile, the already bewildering variety of tasks assigned to overburdened diplomatic missions continued to grow. Transnational legal issues such as terrorism, organized crime, drug trafficking, international smuggling of immigrants and refugees, and human rights increasingly involved embassies in close liaison with local police and prosecutors. As the 20th century ended, however, the number of diplomatic missions maintained by independent states began to decline because of budgetary constraints, the growing practice within the EU of joint diplomatic representation in capitals of relatively little interest to Europe, and greater willingness to accredit ambassadors simultaneously to several regional states.

Joint diplomatic representation

Even as the number of embassies and diplomats devoted to the conduct of bilateral relations contracted, international organizations and conferences attempting to regulate transnational affairs continued to proliferate. Indeed, the number of nongovernmental entities attempting to influence the work of such organizations and conferences grew even more rapidly: churches, the International Red Cross and similar service and relief organizations, multinational corporations, trade unions, and a host of special-interest groups and professional organizations all developed lobbying efforts aimed at advancing specific transnational agendas. Negotiations over tariffs, debts, and issues of market access meanwhile assumed steadily greater importance and came to involve foreign ministries, ministries of trade, and specialized ambassadors-at-large, as well as resident ambassadors and consular officers.

The end of the Cold War left the foreign relations of many countries without a clear direction. Russia struggled to come to terms with its diminished power and influence, brought about by the political and economic collapse of the former Soviet Union. Deprived of its Soviet enemy and unchallenged as a global power, the United States clung to its alliances but deferred less to its allies and found itself increasingly isolated in international forums. Europe progressed toward greater unity without developing a clear vision of its preferred place in the world. Japan more openly aspired to cast off the restrictions on its international role that its defeat in World War II had imposed, but it did little to define or realize this ambition. China and India, which had seen themselves first as victims of European aggression and then as part of a "Third World" between the American and Soviet-led blocs, began uneasily to emerge as great powers in their own right, in the process reviving elements of their long-forgotten ancient diplomatic doctrines and traditions.

The world map itself changed constantly. As the Soviet Union broke up, the Baltic states resumed their independence, and another wave of new states emerged from the retreat of Russian imperialism from Eastern Europe, the Caucasus, and Central Asia. Meanwhile, various multiethnic states (*e.g.*, Yugoslavia) were torn asunder by rampant nationalism. Ethnic minorities, such as Eritreans, achieved self-determination, and civil strife in countries such as Afghanistan, Rwanda, and Somalia resulted in great suffering and huge refugee flows. The need for international intervention to assist the peoples of failed states seemed to increase constantly. In the course of efforts to assign culpability for large-scale human suffering, the walls of sovereign immunity began to be breached. Even current and former heads of state were no longer exempt from the legal process in both international and national courts. At the beginning of the 21st century, there was a consensus that a transition in the diplomatic order was occurring, though there was disagreement about what kind of new order would emerge.

MODERN DIPLOMATIC PRACTICE

Diplomatic agents. In 1961 the Vienna Convention on Diplomatic Relations replaced the rules that had been adopted in the 19th century. It specified three classes of heads of mission: (1) ambassadors or nuncios accredited to heads of state and other heads of missions of equivalent rank, (2) envoys, ministers, and internuncios accredited to heads of state, and (3) chargés d'affaires accredited to ministers of foreign affairs.

A fourth class that had been established in the 19th century, that of minister-resident, lapsed in the 20th century, during which some variations on the other classes were produced. In 1918 Russia's new regime abolished diplomatic ranks. When the Soviet government gained recognition, it accredited "plenipotentiary representatives." Because they lacked precedence under the rules then prevailing, however, the Soviet Union reverted to the previously used titles. The regime of Muammar al-Qaddafi in Libya sent Peoples' Bureaus, which enjoyed precedence under the current rules. Members of the Commonwealth accredited high commissioners to each other. Finally, the Vatican occasionally sent legates on special missions to Roman Catholic countries and in 1965 began to appoint pro-nuncios. It accredited apostolic nuncios only to those few Roman Catholic states where the papal envoy is always the doyen, or dean, of the diplomatic corps; internuncios elsewhere found themselves in the tiny remaining group of ministers. Hence, the title of pro-nuncio was devised to gain entry into the first class.

Rights and privileges. All heads of mission receive the same privileges and immunities, many of which their aides also enjoy. Diplomatic immunity began when prehistoric rulers first realized that their messengers could not safely convey messages, gather intelligence, or negotiate unless the messengers other rulers sent to them were treated with reciprocal hospitality and dignity. Diplomatic agents and their families are inviolable, not subject to arrest or worse, even in wartime. They are largely outside the criminal and civil law in the host state—even as a witness—though many missions waive some exemptions, especially for parking violations. In the host state, the foreign envoy is free of taxes, and his personal baggage is not inspected by the host state or third states crossed in transit, in which he also enjoys immunity.

Extraterritoriality

The head of mission's residence and the chancellery (usually now called the embassy) are extraterritorial. The legal fiction is maintained that these premises are part of the sending state's territory, not that of the host state; even local firefighters cannot enter "foreign territory" without consent. For this reason, political opponents of harsh regimes often seek asylum in embassies, legations, and nunciatures.

The mission's physical property also enjoys immunities and privileges. The flag and emblem of the sending state may be displayed on the chancellery and on the residence and vehicles of the head of mission. The mission's archives and official correspondence are inviolable even if relations are severed or war is declared. The mission is entitled to secure communication with its government; wireless facilities are either afforded or installed at the mission with the host state's consent. Furthermore, the diplomatic bag and couriers also are inviolable.

In their host country, diplomats enjoy the freedom to articulate their government's policies, even when they are unwelcome to the ears of their hosts. Direct criticism of their host government, its leading figures, or local society may, however, result in a diplomat being asked to leave (*i.e.*, being declared *persona non grata*). By long-standing tradition, host states generally seek to restrain the use of intemperate or insulting language by one country's diplomatic representatives against another's (the so-called "third-country rule").

Credentials. Appointment of a new head of mission is a complex process. To avoid embarrassment, his or her name is informally sounded. If the host country does not object, formal application for *agrément*, or consent, is made by the envoy being replaced. Then the new ambassador is sent forth with a letter of credence addressed by his head of state to the head of the host state to introduce the ambassador as his or her representative. In most major capitals, a copy of credentials is now first provided privately to the foreign minister, after which the new ambassador can deal with the foreign ministry and begin to call on his diplomatic colleagues. Presentation of these credentials to the chief of state is, however, quite formal; in some states with a keen sense of tradition, it may entail riding from the embassy to a palace in an open carriage. The ceremony includes handing over the newly arrived ambassador's letters of credence and those of recall of the predecessor and a short platitudinous speech or brief conversation. The date of the formal presentation of credentials determines an ambassador's order of precedence within the local diplomatic corps. At the UN, credentials are presented without ceremony to the secretary-general. There is no doyen, because turnover is too rapid; instead, the secretary-general annually draws the name of a country from a box, and precedence occurs alphabetically in English beginning with that country.

The appointment of consuls is merely notified; they are entitled to only some diplomatic privileges and immunities. They are located in the major cities of the host country, of which a few may be citizens. Consuls issue visas, but their primary functions are fostering commerce and aiding nationals of the sending state who are in difficulty.

Diplomatic tasks. According to the Vienna Convention, the functions of a diplomatic mission include (1) the representation of the sending state at a level beyond the merely social and ceremonial, (2) the protection within the host state of the interests of the sending state and its nationals, including their property and shares in firms, (3) the negotiation and signing of agreements with the host state when authorized, (4) the reporting and gathering of information by all lawful means on conditions and developments in the host country for the sending government, and (5) the promotion of friendly relations between the two states and the furthering of their economic, commercial, cultural, and scientific relations. Diplomatic missions also perform public services for their nationals, including providing electoral registration, issuing passports and papers for military conscription, referring injured or sick nationals to local physicians and lawyers, and ensuring fair treatment for those charged with or imprisoned for crimes.

Services for citizens and the local public are provided by junior and consular staff, whereas specialized attachés engage in protection and much promotional activity. The ambassador is charged with carrying out all the tasks of the diplomatic mission through subordinates or through personal intervention with local authorities when necessary. The head of mission, the head's spouse, and the deputy spend much time entertaining visiting politicians and attending receptions—at which some business is conducted and information is collected—but representation also entails lodging official or informal protests with the host government or explaining and defending national policy. A diplomat's most-demanding daily activities, however, remain reporting, analyzing, and negotiating.

Reports are filed by telegram, telephone, facsimile, and e-mail, usually on an encrypted basis to protect the confidentiality of information. One of the ambassador's key tasks is to predict a developing crisis, a task accomplished through the gathering of information from an array of sources and the use of experience and expert knowledge in identifying, analyzing, and interpreting emerging key issues and patterns and their implications. The ambassador's duty is to advise and warn, and he is expected to brief his government in detail and without distortion about the content of his conversations with the host foreign minister, the prime minister, and other key officials and politicians.

Beyond these functions, the ambassador negotiates as instructed. Negotiation is a complex process leading to agreement based on compromise, if it reaches agreement at all. The topic of negotiation and the timing of initial overtures are set by the ambassador's foreign ministry. The foreign ministry (perhaps with cabinet involvement) also specifies the diplomatic strategy to be used. Usually this is specific to the goals and circumstances. At the end of World War II, for example, the strategy used by the United States to pursue its goals in Europe was the Marshall Plan, which provided financial assistance to several western and southern European countries. The foreign ministry also establishes broad tactics, often regarding initial demands, bargaining counters, and minimum final position. For the rest, the negotiator, either an ambassador or a special envoy, is in most countries free to employ whatever tactics seem best.

Negotiating tactics

In most negotiations, initial demands far exceed expectations; concessions are as small and as slow as possible, for early concession indicates eagerness and engenders demands for more concessions. There is intermittent testing of the other side's firmness and will for an agreement. There may be indirection, lulling the other party, and bluffing to gain an edge, though it is important for diplomats not to be caught bluffing. Lying in diplomatic negotiations is considered a mistake, but stretching or abridging the truth is permissible. Coercive diplomacy involving the threat of force is risky but cheaper than war; other coercive pressures may include conditions for concessions, such as debt rescheduling. Compensations to sweeten the offer, warnings, and threats speed agreement if well timed, as do deadlines, whether agreed, imposed by external events, or contained in ultimatums.

Negotiations vary according to whether the negotiating states are friends or foes, whether they are of similar or disparate power, whether they genuinely want agreement or are negotiating only for propaganda purposes or to avoid condemnation for refusing to negotiate, and whether their aim is to prolong an existing agreement or to change the

status quo, perhaps redistributing benefits or ending hostilities. Some of the most difficult negotiations plow new ground, as do those that create new cooperative or regulatory institutions, such as the International Sea-Bed Authority, and those that transfer authority, such as the 1984 Sino-British agreement by which Chinese sovereignty over Hong Kong was restored in 1997.

Whatever the problem, the diplomatic negotiator must display reliability and credibility. He must try to create trust and to seem both honest and fair, and he must strive to understand the other side's concerns. Stamina, precision, clarity, courage, patience, and an even temper are necessary, though calculated impatience or anger may be used as a tactic. A skilled negotiator has a sense of timing, knowing when to use threats, warnings, or concessions. Sometimes a third party is discreetly used to facilitate initial contact or to press the sides toward agreement. The negotiator must be persuasive, flexible, tenacious, and creative in devising new solutions or reframing issues from a new angle to convince the other party that agreement is in its interest. Smaller and easier issues are tackled first, building an area of agreement, which is then stressed to create a stake in success, while harder issues are postponed or played down. Through a process of proposal and counterproposal, inducement and pressure, the diplomat keeps talking and, in the last analysis, proceeds by trial and error.

Multilateral negotiations demand the same skills but are more complex. The process is usually protracted and fragmented, with subsidiary negotiations in small groups and occasional cooling-off periods. Skillful representatives of small states often play important roles. Decisions are reached by unanimity, majority, or consensus (to avoid voting). For simplicity, decisions are often made to apply across the board, as with tariff cuts.

Iraq's refusal to end its occupation of Kuwait peacefully in 1990 and the failure of Israel and the Palestinians from the mid-1990s to reach a negotiated settlement of their disputes are sad reminders that when negotiations fail, the consequences can be bloody. In the end, war, not words, remains the ultimate argument of the state. What cannot be decided through dialogue by diplomats or leaders over a negotiating table is often left to be decided on the battlefield or in civil conflict.

Diplomatic agreements. If a negotiation succeeds, the result is embodied in an international instrument, of which there are several types. The most solemn is a treaty, a written agreement between states binding on the parties under international law and analogous to a contract in civil law. Treaties are registered at the UN and may be bilateral or multilateral; international organizations also conclude treaties both with individual states and with each other.

Treaties and conventions

A convention is a multilateral instrument of a law-making, codifying, or regulatory nature. Conventions are usually negotiated under the auspices of international entities or a conference of states. The UN and its agencies negotiate many conventions, as does the Council of Europe. Treaties and conventions require ratification, an executive act of final approval. In democratic countries, parliamentary approval is deemed advisable for important treaties. In the United States, the Senate must consent by a two-thirds vote. Elsewhere, legislative involvement is less drastic but has increased since World War II. In Britain, treaties lie on the table of the House of Commons for 21 days before ratification; other countries have similar requirements. For bilateral treaties, ratifications are exchanged; otherwise, they are deposited in a place named in the text, and the treaty takes effect when the specified number of ratifications have been received.

Agreements are usually bilateral, not multilateral. Less formal and permanent than treaties, they deal with narrow, often technical topics. They are negotiated between governments or government departments, though sometimes nongovernmental entities are involved, as banks are in debt-rescheduling agreements. U.S. presidents have long used executive agreements to preserve secrecy and to circumvent the ratification process.

A protocol prolongs, amends, supplements, or supersedes an existing instrument. It may contain details pertaining to the application of an agreement, an optional arrangement extending an obligatory convention, or a technical instrument as an annex to a general agreement. It may substitute for an agreement or an exchange of notes, which can be used to record a bilateral agreement or its modification.

International instruments have proliferated since World War II: between 1945 and 1965 there were about 2,500 multilateral treaties, more than in the previous 350 years. As the countries of the world have become more interdependent, this trend has continued. Most multilateral agreements are negotiated by conferences. The negotiations are numerous and often protracted.

Conference diplomacy. Professional diplomats are rarely dominant in conferences, where the primary role is usually played by politicians or experts—especially at summits, the most spectacular type. Heads of state or government or foreign ministers meet bilaterally or multilaterally. Summit diplomacy can be risky, a point made in the 15th century by the Burgundian diplomat and chronicler Philippe de Commynes, who wrote, "Two great princes who wish to establish good personal relations should never meet each other face to face, but ought to communicate through good and wise emissaries." Summits also raise expectations; if poorly prepared, they can be disastrous failures. As former U.S. secretary of state Dean Acheson once remarked, "When a chief of state or head of government makes a fumble, the goal line is open behind him." Haste can also lead to bad bargains or murky texts. On the other hand, the development of personal relationships between leaders can be an asset, and political leaders can speed agreement by setting guidelines or deadlines and cutting through bureaucratic thickets. Summits put professional diplomats briefly into the shade but rarely hurt their standing unless there is constant intervention in their work by political leaders or other officials. Indeed, a visit by the foreign minister can be an asset to an ambassador by serving to raise his standing.

Summits

A summit is often preceded or followed by coalition diplomacy. This necessary joint working out of common policies or responses to proposals by cabinet ministers may be fairly informal. Coalitions require cumbersome two-step diplomacy at each stage, arriving at a joint policy and then negotiating with the other party.

Larger conferences are called, often under UN auspices, to address specific problems. The more technical the topic, the larger the role played by specialists. The trend over the last two decades of the 20th century was toward numerous conferences on social, economic, and technical issues. Many conferences produce agreements that create international law, often in new areas. In some cases, the negotiations leading to these agreements are cumbersome. In 1973–75, for example, all 35 states involved in the Geneva Conference on Security and Cooperation in Europe, which led to the Helsinki Accords, participated actively under a unanimity rule. In other cases, the negotiations are protracted, as they were in the Law of the Sea conferences, which lasted more than a decade.

International organizations play several roles in multilateral negotiations, including sponsoring conferences and encouraging coalition diplomacy. The Arab League, the Association of Southeast Asian Nations, and the EU attempt to create a unified policy for their members. Regular meetings of the UN, its agencies, and regional organizations provide forums for parliamentary diplomacy, propaganda, and negotiation. International bureaucracies negotiate with each other and with individual states. This is particularly true of the UN and the EU, the latter of which has assumed some attributes of sovereignty. UN peacekeeping forces have played an important role, and the secretary-general engages in third-party diplomacy to bring feuding states to agreement or at least to keep them talking until the quarrel has faded. States, specialized agencies, and regional entities also conduct third-party diplomacy.

Personnel. Diplomatic personnel undergo rigorous selection and training before representing their country abroad. Except in a few cases, those conducting diplomacy are usually professional diplomats or specialists with the title of attaché. Some regimes still use ambassadorships to exile political opponents; others, such as Britain, deviate

Professional diplomats

from career appointments occasionally for special but non-political reasons. Despite much empirical evidence to suggest that the practice is unwise, U.S. presidents continue to reward major campaign contributors with choice embassies. Even when the ambassador is an amateur, however, other staff members, almost without exception, are career professionals.

Applicants for diplomatic positions generally are university graduates who face grueling oral and written examinations, which few survive. These exams test an applicant's skills in writing, analyzing, and summarizing and the ability to spot essentials and deal with problems, as well as persuasiveness, poise, intelligence, initiative, and stability. As a result of attempts by advanced industrial countries to diversify the educational, ethnic, social, and geographic backgrounds of their diplomatic staffs, foreign-language proficiency is no longer required for entrance into diplomatic training programs; all states educate accepted candidates in languages and etiquette. Despite diversification, the best-educated and most-poised candidates tend to succeed.

All countries agree on the need for proficiency in foreign languages. Diplomats speaking English, French, and Spanish are maintained, and countries often seek candidates with skills in other languages, such as Arabic, Chinese, German, Japanese, Portuguese, Russian. Language training is provided at a foreign service institute, at local universities, or abroad. Most states also stress knowledge of economics, geography, international politics, and law, and many teach their own history and culture. Some provide added academic training; others, including the United States, are more practical in orientation. In the debate over whether career officers should be generalists or specialists, the United States favours modest specialization—for example, in African economics—whereas many states prefer generalists, particularly small countries that cannot afford specialists.

There are three basic approaches to training. Britain and some Commonwealth states couple brief orientation with a long apprenticeship and on-the-job training, some of which occurs in all systems. The French method, also widely imitated, entails intensive training in a school of public administration, in some states with added specialization. India combines the British and French styles in a three-year program. Prospective Brazilian, Egyptian, and German diplomats train for one to three years in an academy that is usually staffed by a combination of senior diplomats and academics and run by the foreign ministry. The United States has no diplomatic academy; instead, it offers highly focused vocational and language training to its diplomats as needed.

Training presents special problems for small new countries, which often use facilities offered by the UN and the Diplomatic Academy of Vienna. A few regional training centres also have been established. Most foreign services, however, rely on a combination of university training and on-the-job apprenticeship.

Structure of the foreign ministry

Once trained, career diplomats serve their foreign ministry abroad or staff it at home. Foreign ministries are similarly organized. They are led by the foreign minister, who is usually a member of the cabinet or dominant political body. In most countries, except those governed by dictatorships, he often belongs to the legislature, though the U.S. secretary of state does not. Some states use the British system of parliamentary undersecretaries to handle legislative responsibilities. Otherwise, except for the minister's staff, employees are civil servants led by a permanent undersecretary or secretary-general, who runs the ministry. The United States is unusual in that it does not have a professional director and the entire top echelon of its diplomatic corps—deputy secretary, undersecretaries and their deputies, and assistant secretaries—is made up of political appointees who are changed with each administration.

Except in the smallest states, foreign ministries are organized both geographically and functionally. The functional departments include administration, personnel, finance, economic affairs, legal affairs, archives, and perhaps offices dealing with science, disarmament, narcotics, and cultural diplomacy. Geographic division is generally by region, subdivided into country desks that deal with accredited embassies and their own missions abroad. Envoys from other states normally see the senior area specialist or the regional assistant secretary, as foreign ministers do not have time to see more than selected ambassadors of a few key countries for especially important questions. Although generalists are preferred in most foreign ministries, some area and country staff will have significant expertise. Despite rotation, this is particularly true in the United States, where career officials specialize in political, economic, administrative, or consular work. All foreign ministries are staffed in varying ratios by two kinds of career diplomat: civil servants based in the capital and foreign service officers on periodic home assignment. Whichever kind they may be and wherever they may serve, they use diplomacy to pursue their country's interests, to engage in international discourse, and to alleviate friction between sovereign states.

BIBLIOGRAPHY. CHAS. W. FREEMAN, JR., *Arts of Power: Statecraft and Diplomacy* (1997), explores the relationship between statecraft and diplomacy and analyzes the functions of diplomats, and *The Diplomat's Dictionary*, rev. ed. (1997), is a compendium of diplomatic quotations and lore. Disease

Disease is considered to be a harmful deviation from the normal structural or functional state of an organism. A diseased organism commonly exhibits signs or symptoms indicative of its abnormal state. Thus, the normal condition of an organism must be understood in order to recognize the hallmarks of disease. Nevertheless, a sharp demarcation between disease and health is not always apparent.

The study of disease is called pathology. It involves the determination of the cause (etiology) of the disease, the understanding of the mechanisms of its development (pathogenesis), the structural changes associated with the disease process (morphological changes), and the functional consequences of these changes. Correctly identifying the cause of a disease is necessary to identifying the proper course of treatment.

Humans, animals, and plants are all susceptible to diseases of some sort. However, that which disrupts the normal functioning of one type of organism may have no effect on the other types. Thus, the study of disease in each type of organism is treated in a separate section in this article.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 422 and 423, and the *Index*.

This article is divided into the following sections:

THE NATURE OF DISEASE

Major distinctions

The normal state of an organism represents a condition of delicate physiological balance, or homeostasis, in terms of chemical, physical, and functional processes, maintained by a complex of mechanisms that are not fully understood. In a fundamental sense, therefore, disease represents the consequences of a breakdown of the homeostatic control mechanisms. In some instances the affected mechanisms are clearly indicated, but in most cases a complex of mechanisms is disturbed, initially or sequentially, and precise definition of the pathogenesis of the ensuing disease is elusive. Death in human beings and other mammals, for example, often results directly from heart or lung failure, but the preceding sequence of events may be highly complex, involving disturbances of other organ systems and derangement of other control mechanisms.

The initial cause of the diseased state may lie within the individual organism itself, and the disease is then said to be idiopathic, innate, primary, or "essential." It may result from a course of medical treatment, either as an unavoidable side effect or because the treatment itself was ill-advised; in either case the disease is classed as iatrogenic. Finally, the disease may be caused by some agent external to the organism, such as a chemical that is a toxic agent. In this case the disease is noncommunicable; that is, it affects only the individual organism exposed to it. The external agent may be itself a living organism capable of multiplying within the host and subsequently infecting other organisms; in this case the disease is said to be communicable.

NONCOMMUNICABLE DISEASE

Metabolic defects. Noncommunicable diseases arise from genetically determined metabolic abnormalities present at birth that leave the organism ill-equipped to deal with the natural materials it encounters in its daily life. In human beings, for example, the lack of a certain enzyme necessary for the metabolism of the common amino acid phenylalanine leads to the disease phenylketonuria (or PKU), which appears at a few weeks of age and, if not treated, is often associated with mental retardation. Other metabolic defects may make their appearance only relatively late in life. Examples of this situation are the diseases gout and late-onset, or adult-type, diabetes. Gout results from an accumulation within the tissues of uric acid, an end product of nucleic acid metabolism. Late-onset diabetes results from an impaired release of insulin by the pancreas and a reduction in responsiveness of body tissues to insulin that lead to the inability to metabolize sugars and fats properly. Alternatively, the metabolic fault may be associated with aging and the concomitant deterioration of control mechanisms, as in the loss of calcium from bone in the condition known as osteoporosis. That

these late-developing metabolic diseases also have a genetic basis—that is, that there is an inherited tendency for the development of the metabolic faults involved—seems to be definitely the case in some instances but remains either incompletely understood or uncertain in others.

Environmental hazards. Metabolic derangements also may result from the effects of external environmental factors, a relationship that would be suggested by the apparent confinement of a disease to sharply delimited geographic areas. Notable examples are goitre and mottled enamel of the teeth in humans. The development of goitre is attributable to iodine deficiency in the diet, which leads to compensatory growth of the thyroid gland in a vain effort to overcome the deficiency. The disease tends to occur in inland areas where seafood consumption is minimal and dietary supplementation of iodine—through such items as table salt—does not occur. Mottled enamel of teeth results from consumption of excessive amounts of fluoride, usually in water supplies, but conversely, dental caries (tooth decay) is found to occur to a greater extent in areas in which water supplies are deficient in fluoride. Analogous conditions in herbivorous domesticated animals result from deficiencies in trace elements, such as zinc and selenium, in the soil of pastures and, therefore, also in plants making up the diet. Similarly, plant growth suffers from soil deficiencies of essential elements, particularly nitrogen, potassium, and phosphorus. These conditions can be corrected by adding salts to the diets of domesticated animals and by applying fertilizers to soil.

Deficiency diseases

There also are diseases resulting from toxic substances added to the environment in sufficient amounts to produce symptoms of greater or lesser severity. Although human disorders of this nature are best known, untoward effects of such contamination of the environment occur also in plants and animals. The problems caused by environmental toxic agents are largely, if not entirely, anthropogenic. Best known of the environmental diseases, perhaps, are the occupational diseases, especially those of the respiratory tract, including asbestosis, silicosis, and byssinosis (caused by inhalation of, respectively, asbestos, silica, and cotton dust). Also important in this regard are metal poisoning, as with mercury, lead, and arsenic; poisoning with solvents used in industrial processes; and exposure to ionizing radiation. Of greater importance to the population at large are the diseases that result from exposure to insecticides and atmospheric pollutants. Such diseases usually, though not invariably, are of a chronic nature; they require prolonged exposure to the noxious agent and develop slowly. Environmental diseases of all kinds, however, also may predispose the individual to other diseases; for example, respiratory diseases such as silicosis render the sufferer more susceptible to tuberculosis.

COMMUNICABLE DISEASE

Host-parasite relationships. Communicable, or contagious, diseases are those transmitted from one organism to another; infectious diseases are diseases caused in the host by infection with living, and therefore replicating, microorganisms such as animal parasites, bacteria, fungi, or viruses. Practically, these two classes of disease are the same, because infectious diseases generally are communicable, or transmissible, from one host to another, and the causative agent, therefore, is disseminated, directly or indirectly, through the host population. Such spread is an ecological phenomenon, the host serving as the environment in which the parasite lives; complexity arises when the parasite occurs in more than one host species. The host-parasite relationship, therefore, must be considered not only with respect to the individual host-parasite interaction but also in terms of the interrelationship between the host and parasite populations, as well as those of any other host species involved.

Disease as an ecological problem

Most pathogenic bacteria are obligate parasites; that is, they are found only in association with their hosts. Some, such as staphylococci and streptococci, can proliferate outside the body of the host in nutritive materials infected from host sources. Within the tissues of the host, these organisms set up local infections that spread throughout the body. Still other bacteria, such as the glanders bacillus and the gonococci, meningococci, and pneumococci, are more closely adapted parasites, capable of multiplying outside the body of the host only under the artificial conditions of the laboratory. All these microorganisms have complete cell structures and metabolic capabilities.

A greater degree of dependence on the host is shown by rickettsiae and viruses. Rickettsiae are microorganisms that have the cell structure of bacteria; they exhibit a small degree of metabolic activity outside cells, but they cannot grow in the absence of host tissue. The ultimate in parasitism, however, is that of the viruses, which have no conventional cell structure and consist only of a nucleic acid (either DNA or RNA) wrapped in a protective protein coat. Viruses are obligatory intracellular parasites, capable of multiplying only within the cells of the host, and they have no independent metabolic activity of their own. The genetic information that directs the synthesis of virus materials and certain enzymes enters the host cell, parasitizes its chemical processes, and directs them toward the synthesis of new virus elements.

These various degrees of parasitism suggest that the host-parasite relationship is subject to continuing evolutionary change. The adaptation of the microorganism to its parasitic existence, in this view, is accompanied by progressive loss in metabolic capability, with eventual complete physiological dependence of the parasite on the host.

Parasite specificity. The condition of obligate parasitism is associated with a degree of specificity of the parasite with regard to the host; *i.e.,* the parasite generally is more closely adapted to one species of host than to all others. Microorganisms adapted to plant hosts, with only rare exception, are unable to infect animal hosts, and conversely microorganism parasites of animals rarely occur in plants. A number of host species may be susceptible to infection with a given parasite, and the pattern of host susceptibility need not correspond with taxonomic relationships, including hosts varying as widely as vertebrates and invertebrates.

The ability to produce consistently fatal disease in a host is often of negative survival value to the parasite, because it is quite likely to eliminate quickly all available hosts. Consistent with this, there is a tendency for disease resulting from infection to be less severe when adaptation of the parasite to the host has become close. A change in severity of a disease, presumably resulting from adaptation, has been observed in the case of the spirochete that causes syphilis, with the disease in human beings being less severe today than it was in the 16th century. However, ecological studies of parasitism indicate that it is incorrect to assume that all host-parasite relationships will evolve toward reduced antagonism and that a resultant disease state eventually will be ameliorated. (For further information see BIOSPHERE: *Community ecology.*)

Adaptation of parasite to host

Disease produced in related host species may be either milder or more severe than in the definitive host. In certain cases, adaptation is so close that the parasite is unable to infect any other hosts under natural conditions; this is true of many microorganisms producing disease in humans. On the other hand, natural infection of secondary hosts may occur, leading to severe or fatal disease. Rabies, for example, is a fatal disease in almost all animal hosts. In some species such as the bat, however, the virus may persist for long periods as an asymptomatic infection.

Host resistance. The specificity of pathogenic microorganisms with regard to their hosts is an expression not only of differences in microbial character but also of differing host resistance. The ability of a microorganism to produce disease can be evaluated only in terms of the host reaction, and conversely the resistance, or immunity, of the host can be judged only with regard to its effect on the microorganism. In short, the two are but different facets of the same phenomenon, and either may be evaluated by holding the other constant and varying it. Commonly, for example, virulence of an infective agent is determined experimentally by inoculating groups of hosts with graded doses of the agent and determining, by interpolation, the dose that produces a typical reaction in 50 percent of the host individuals inoculated. This dose is termed the 50-percent-effective dose, or ED_{50}; it is related in inverse

fashion to virulence and in a direct way to resistance. In other words, in a given host, the higher the 50-percent-effective dose, the less virulent the infective organism; or, with a microorganism of known virulence, the higher the ED_{50} with the host it is tested against, the greater the resistance of that particular host. Customarily, in different host species, resistance is expressed as an *n*-fold increase or decrease (with *n* equal to a whole number) in the ED_{50} over that of the normal host species.

Distribution of resistance and virulence

This kind of assay is possible because both virulence and resistance tend to occur in approximately normal, or bell-shaped, frequency distributions; that is, most members of the host and microorganism populations occupy a central position with regard to these properties, exceptional individuals appearing at both extremes. With reference to host resistance, this explains the varied incidence of disease in a host population exposed to a statistically constant dose of the infectious agent. In most practical considerations the dose is only statistically constant, for it varies greatly from one host to another depending on circumstances relating to transfer of the infectious agent. Individual variation in host resistance to infection, however, is due to more than mere numbers of infectious agents encountered; it also results from innate factors in the individual host organism. At any rate, variation in host resistance means that not all individuals making up a population essentially universally susceptible to infection with newly appearing infectious agents will contract the disease on first exposure.

Apparent and inapparent infection. Because infection is not an all-or-nothing affair, individual variation in resistance to disease also results in different degrees of reaction to the infectious agent; *i.e.,* the outcome of the interaction of host and parasite is variable in each individual instance. Some individual hosts show symptoms typical of the disease, and infection is readily recognized. Others, having greater resistance, exhibit symptoms of the disease in only a mild or atypical form, and infection in these individuals may not be clearly recognizable. Still other host organisms become infected with the invading parasite but show no symptoms of the disease. Distinction, therefore, must be made between infection and disease, the former occurring on occasion without any sign of the latter. There may be, of course, no such thing as totally asymptomatic infections. What are taken to be such may be, in fact, only those infections with symptoms occurring beneath the level of observation. Nonetheless, such inapparent infections, or "carrier" states, clearly exist and serve to transmit the infection to susceptible hosts.

The overt consequence of infection of a host population of relatively high resistance is the sporadic occurrence of cases of disease and a high carrier-case ratio. The infection, in other words, is widely prevalent in the host population in asymptomatic form, and the relatively rare observed cases of disease represent the highly susceptible few in the host population making up one extreme of the bell-shaped frequency distribution curve. Examples of human diseases of this kind are poliomyelitis, meningococcal meningitis, and cholera.

This type of irregularity in the occurrence of cases of disease tends to occur in host populations of high, but not too high, resistance to the infectious agent. If host resistance is too high, or too low, the disease will die out: in the former case, because the infective agent is unable to maintain itself and, in the latter, because it eliminates the host. One of the best-known illustrations of the importance of relative host resistance to survival of the parasite is that of the plague bacillus. Plague is primarily a disease of rodents and persists as foci of infection in these hosts. The black rat and the less susceptible gray sewer rat are commonly associated with this disease but are too susceptible to allow its persistence; *i.e.,* the host is destroyed. The infection persists, however, in relatively resistant wild rodents.

Foci of infection

Inheritance of resistance. That there exists genetic control of resistance is suggested by the mere fact of host specificity, and such control has been demonstrated amply by experimental studies on both plant and animal hosts. The former, for example, had wide practical application in the development, by selective breeding, of strains and races of plants of economic importance, especially grains, that are resistant to a wide variety of plant diseases.

In general, resistance developed by selective breeding is only partially specific; that is, the observed resistance to infection with pathogenic microorganisms, and to the toxins of such organisms, is manifested toward groups of related microorganisms producing similar diseases, not to single organisms alone. Although resistance to disease has been found in a few instances to be a function of a single gene, in most cases several genes are involved.

Racial differences

For many years there has been considerable interest in the possibility of differences in resistance to disease associated with the different human populations. While marked differences in morbidity and mortality occur between whites and nonwhites in the United States, for example, it is often difficult to rule out differences in exposure to infection, socioeconomic factors, and differential application of preventive and therapeutic measures in accounting for them. Nevertheless, there are fragmentary indications that there may be sufficient genetic segregation among races to result in differences in resistance to certain diseases. The case fatality rate in tuberculosis appears to be lower in Jews than in others, for example, and gonorrhea seems to be a less serious disease in blacks than in whites.

Epidemiology. The interaction of host and parasite populations constitutes the subject matter of epidemiology (the term being more inclusive than suggested by its relation to the word epidemic). In most instances the epidemiology of infectious disease is characteristic of that disease and is an outgrowth of biological properties of the parasite and the host, including host specificity and the behaviour of the host species as populations.

Aside from the saprophytic microorganisms that occasionally produce disease, most pathogenic microorganisms are adapted sufficiently closely to their hosts that they cannot compete successfully in the physical, chemical, and biological environment outside the host tissues. Exceptions to this generalization occur in the cases of those microorganisms whose life history includes a resistant spore stage. This occurs with various fungi responsible for plant disease, as well as certain parasites of animals. Among the latter are species of the fungus *Coccidioides,* which infect both rodents and humans (producing desert fever in the latter), and the anthrax bacillus, which causes disease in cattle, sheep, and other domesticated animals and occasionally infects humans as well. A disease of animals that can be transmitted to humans is called a zoonosis.

Survival of the parasite ordinarily requires that it be transmitted more or less directly from an infected host organism to a susceptible one. The precise route of infection often is of primary importance, with some microorganisms requiring direct access to internal tissue, some being able to initiate infection on mucous membranes of the nose and throat, and others able to establish primary infections in the intestinal tract. These particular modes of infection generally occur by way of, respectively, biting insects, coughing and sneezing, and contamination of food and water.

The role of vector hosts

The occurrence of a given parasite in more than one host species may markedly affect its epidemiological character; it may persist, for example, in one or another of its hosts as a reservoir of infection, sallying forth to encounter the alternate host only on occasion. It is fairly common to find transmission of a parasite from one vertebrate or plant host to another occurring by means of an insect carrier, or vector. Often animal parasites have intermediate hosts in which one or more phases of their life cycles occur; this results in an obligatory sequence of hosts in the life history of the parasite. With the disease schistosomiasis in humans, for example, the blood flukes responsible for the disease (*Schistosoma* species) spend one phase of their larval life in snails. Under such circumstances, and they are not uncommon, the dissemination of the parasite in a host population is dependent not only on the interaction of the parasite population with that of the host population but also on the interaction of the intermediate or vector host population with both parasite and host populations.

Such interrelationships may be the basis of geographic and seasonal differences in the incidence of disease. An

insect-borne disease transmitted from one host species to another requires the simultaneous presence of all three populations in sufficient numbers for its dissemination. Such a circumstance may be sharply limited by location and season.

Behavioral patterns of host populations often have a great effect on the transmission of infectious agents. Crowding, for example, facilitates the spread of infection. Bovine tuberculosis is largely a disease of domesticated cattle in barns, and the age incidence of the human diseases of childhood is lower in urban than in rural populations, suggesting that in the more crowded urban environment children are exposed to disease at an earlier age.

When a disease is prevalent in an area over long periods of time, it is considered to be endemic in that area. When the prevalence of disease is subject to wide fluctuations in time, it is considered to be epidemic during periods of high prevalence. Epidemics prevailing over wide geographic areas are called pandemics.

Epidemic waves

Epidemic prevalence of disease occurs in a wave, the number of cases rising to a peak and then declining. The period of increase occurs when each case gives rise to more than one additional case—*i.e.,* when the parasite population is growing more rapidly than the host population. The decline occurs when each case gives rise to less than one new case—*i.e.,* when the parasite population begins to die off because it encounters only immune individuals among the host population. The rise and fall in epidemic prevalence of a disease is a probability phenomenon, the probability being that of transfer of an effective dose of the infectious agent from the infected individual to a susceptible one. After an epidemic wave has subsided, the affected host population contains such a small proportion of susceptible individuals that reintroduction of the infection will not result in a new epidemic. Because the parasite population cannot reproduce itself in such a host population, the entire host population is immune to the epidemic disease, a phenomenon termed "herd" immunity.

Following such an epidemic, however, the host population immediately tends to revert to a condition of susceptibility because of (1) the deterioration of individual immunity, (2) the removal of immune individuals by death, and (3) the influx of susceptible individuals by birth. In time the population as a whole again reaches the point at which it is susceptible to epidemic disease. This pattern of rising and falling herd immunity explains why epidemic diseases tend to occur in waves—*i.e.,* exhibit a periodicity in prevalence. The time elapsing between successive epidemic peaks is variable and differs from one disease to another.

Immunity. Humans and all other vertebrates react to the presence of parasites within their tissues by means of immune mechanisms of which there are two types: nonspecific, innate immunity and specific, acquired immunity. Innate immunity, with which an organism is born, involves protective factors, such as interferon, and cells, such as macrophages, granulocytes, and natural killer cells, and its action does not depend on prior exposure to a pathogen. Specific immunity is acquired during the organism's lifetime and involves the activation of white blood cells (B and T lymphocytes), which distinguish and react to foreign substances. B lymphocytes operate by producing antibodies, proteins that neutralize foreign molecules (antigens), while T lymphocytes directly attack invaders. Many immune responses, however, involve both mechanisms.

Although the immune response is primarily defensive in nature, it may contribute in some cases to the pathogenesis of the disease. In rheumatic fever, for example, sensitivity to antigens of the causative streptococcus organism, which cross-react with host tissue antigens, is associated with the progress and adverse aspects of the disease. The immune response to various environmental substances, such as plant pollens and chemotherapeutic drugs, also is responsible for the diseases grouped under the general head of allergies. The immune response itself may become deficient in human diseases involving white cells, such as multiple myeloma, macroglobulinemia, Hodgkin's disease, and chronic lymphocytic leukemia. Such diminished immune responses, however, seem to be of minor significance to the course of these diseases, although, when the disease is sufficiently severe and prolonged, it can increase the risk of opportunistic infections, which can be fatal.

Auto-immune disease

One category of disease is associated with an immune response to antigenic components of the host itself (autoantigens). These diseases, called autoimmune diseases, include rheumatoid arthritis and systemic lupus erythematosus. (For a more detailed explanation of the immunologic system, see IMMUNITY.)

Control of disease

PREVENTION

Most diseases are preventable to a greater or lesser degree, the chief exceptions being the idiopathic diseases, such as the inherited metabolic defects. In the case of those diseases resulting from environmental factors, prevention is a matter of eliminating, or sharply reducing, the responsible material in the environment. Because these materials originate largely from human activities, prevention ought to be a simple matter of the application of well-established principles of industrial hygiene. In practice, however, this is often difficult to achieve.

The infectious diseases may be prevented in one of two general ways: (1) by preventing contact, and therefore transmission of infection, between the susceptible host and the source of infection and (2) by rendering the host unsusceptible, either by selective breeding or by induction of an effective artificial immunity. The nature of the specific preventive measures, and their efficacy, varies from one disease to another.

Quarantine

Quarantine, which is an effective method of preventing transmission of disease in principle, has had only limited success in actual practice. In only a few instances has quarantine achieved prevention of the spread of disease across international borders, and quarantine of individual cases of human disease has long been abandoned as ineffective.

It has not been possible to prevent effectively the dissemination of airborne disease, notably airborne fungal diseases of plants and human diseases of the upper respiratory tract. Nor is disease ordinarily controllable by elimination of reservoirs of infection, such as those that occur in wild animals. There are certain exceptions in which the reservoir of infection can be greatly reduced, however; for example, chemotherapy of human tuberculosis may render individual cases noninfectious, and slaughtering of infected cattle may reduce the incidence of bovine tuberculosis.

When infection is spread less directly, through the agency of living vectors or inanimate vehicles, it is often possible to break one or more of the links connecting the susceptible host with the source of infection. Malaria can be controlled effectively by the elimination of the mosquito vector, and louse-borne typhus in humans can be regulated by disinfestation methods. Similarly, diseases spread in epidemic form through the agency of water or milk are controlled by measures such as the chlorination of public water supplies and the pasteurization of milk.

Artificial immunization

Artificial immunization against certain diseases provides immunity and may be used in these instances, particularly when other methods of control are impractical or ineffective. The mass immunization of children in their early years has been highly effective in the control of diphtheria, smallpox, and poliomyelitis. Under special circumstances, as in certain military populations, it has been possible to control with prophylactic medicinal agents the spread of disease for which effective vaccines have not been developed.

TREATMENT

Treatment of disease in the affected individual is twofold in nature, being directed (1) toward restoration of a normal physiological state and (2) toward removal of the causative agent. The diseased organism itself plays an active part in both respects, having the capacity for tissue proliferation to replace damaged tissue and to surround and wall off the noxious agent, as well as defense and detoxification mechanisms that remove the causative agent and its products

or render them harmless. Therapy of disease supplements and reinforces these natural defense mechanisms.

Metabolic faults also may sometimes be corrected—for example, by the use of insulin in the treatment and control of diabetes—but more often specific therapeutic measures for idiopathic diseases are lacking. However, advances in gene therapy may be able to correct defective genes that result in disease.

When disease is produced by environmental factors, there is commonly no specific treatment; only removal of the affected individual from exposure to the agent generally allows normal detoxification responses to take over. Again, there are notable exceptions, as in the treatment of lead poisoning with ethylenediaminetetraacetic acid, an agent that forms complexes with lead that are excreted by the kidney.

Treatment of infectious diseases is more effective in general; it assumes several different forms. Treatment of diphtheria with antitoxin, for example, neutralizes the toxin formed by the microorganisms, and host defense mechanisms then rid the body of the causative microorganisms. In other diseases, treatment is symptomatic in the sense of restoring normal body function. An outstanding example of this is in cholera, in which disease symptoms result from a massive loss of fluid and salts and from a metabolic acidosis; the highly effective treatment consists of restoring water and salts, the latter including bicarbonates or lactates to combat acidosis. More often, however, therapy is directed against the infecting microorganism by administration of drugs such as sulfonamides or antibiotics. While some of these substances kill the microorganisms, others do not and instead inhibit proliferation of the microorganism and give host defenses an opportunity to function effectively. For other infectious diseases there is no specific therapy. There are, for example, very few antiviral chemotherapeutic agents; treatment of viral diseases is mainly directed toward relief of discomfort and pain, and recovery, if it ensues, is largely a matter of an effective cellular immune response mounted against the invading virus by the host. (W.Bu./D.G.Sc.)

HUMAN DISEASE

Health versus disease

The meaning of health

Before human disease can be discussed, the meanings of the terms health, physical fitness, illness, and disease must be considered. Health could be defined theoretically in terms of certain measured values; for example, a person having normal body temperature, pulse and breathing rates, blood pressure, height, weight, acuity of vision, sensitivity of hearing, and other normal measurable characteristics might be termed healthy. But what does normal mean, and how is it established?

Biological criteria of normality are based on statistical concepts. Body height may be used as an example. If the heights of every individual in a large sample were plotted on a graph, the many points would fall on a bell-shaped curve. At one end of the curve would be the very short people, and at the other extreme the few very tall people. The majority of the points of the sample population would fall on the dome of the bell-shaped curve. At the peak of the dome would be those individuals whose height approaches the average of all the heights. Scientists use curves in determining what they call normal criteria. By accepted statistical criteria, 95 percent of the population measured would be included in the normal range—that is, 47.5 percent above and 47.5 percent below the mean at the very centre of the bell. Looked at in another way, in any given normal biological distribution 5 percent will be considered outside the normal range. Thus the 7-foot (213-centimetre) basketball player would be considered abnormally tall, but that which is abnormal must be distinguished from that which represents disease. The basketball player might be abnormally tall but still have excellent health. Thus, in any statistical analysis of health, the possibility of biological variation must be recognized.

A better example than height of how problems can arise with biological variability is heart size. If the heart is subjected to a greater than normal burden over a long period, it can respond by growing larger (the process is known as hypertrophy). This occurs in certain forms of heart disease, especially in those involving long-standing high blood pressure or structural defects of the heart valves. A large heart, therefore, may be a sign of disease. On the other hand, it is not uncommon for athletes to have large hearts. Continuous strenuous exercise requires a greater output of blood to the tissues, and the heart adapts to this demand by becoming larger. In some cases the decision as to whether an abnormally large heart represents evidence of disease or is simply a biological variant may tax the diagnostic abilities of the physician.

The effects of age

The effects of age introduce yet another difficulty in the attempt to define health in theoretical measured norms. It is well known that muscular strength diminishes in the advanced years of life, the bones become more delicate and more easily fractured, vision and hearing become less sharp, and a variety of other retrogressive changes occur. There is some basis for considering this general deterioration as a disease, but, in view of the fact that it affects virtually everyone, it can be accepted as normal. Theoretical criteria for health, then, would have to be set for virtually every year of life. Thus, one would have to say that it is normal for a man of 80 to be breathless after climbing two flights of stairs, while such breathlessness would be distinctly abnormal in an agile child of 10 years of age. Moreover, an individual's general level of physical activity significantly alters his ability to respond to the ordinary demands of daily life. The amount of muscular strength possessed by an 80-year-old man who has remained physically active would be considerably more than that of his fragile friend who has led a confined life because of his dislike of activity. There are, therefore, many difficulties in establishing criteria for health in terms of absolute values.

Health might be defined better as the ability to function effectively in complete harmony with one's environment. Implied in such a definition is the capability of meeting—physically, emotionally, and mentally—the ordinary stresses of life. In this definition health is interpreted in terms of the individual's environment. Health to the construction worker would have a dimension different from health to the bookkeeper. The healthy construction worker expects to be able to do manual labour all day, while the bookkeeper, although perfectly capable of performing sedentary work, would be totally incapable of such heavy labour and indeed might collapse from the physical strain; yet both individuals might be termed completely healthy in terms of their own way of life.

Physical fitness

The term physical fitness, although frequently used, is also exceedingly difficult to define. In general it refers to the state of optimal maintenance of muscular strength, proper function of the internal organs, and youthful vigour. The champion athlete prepared to cope not only with the commonplace stresses of life but also with the unusual illustrates the concept of physical fitness. To be in good physical condition is to have the ability to swim a mile to save one's life or to slog home through snowdrifts when a car breaks down in a storm. Some experts in fitness insist that the state of health requires that the individual be in prime physical condition. They prefer to divide the spectrum of health and disease into (1) health, (2) absence of disease, and (3) disease. In their view, those who are not in prime condition and are not physically fit cannot be considered as healthy merely because they have no disease.

Health involves more than physical fitness, since it also implies mental and emotional well-being. Should the angry, frustrated, emotionally unstable person in excellent physical condition be called healthy? Certainly this individual could not be characterized as effectively functioning in complete harmony with the environment. Indeed, such

an individual is incapable of good judgment and rational response. Health, then, is not merely the absence of illness or disease but involves the ability to function in harmony with one's environment and to meet the usual and sometimes unusual demands of daily life.

The definitions of illness and disease are equally difficult problems. Despite the fact that these terms are often used interchangeably, illness is not to be equated with disease. A person may have a disease for many years without even being aware of its presence. Although diseased, this person is not ill. Similarly, a person with diabetes who has received adequate insulin treatment is not ill. An individual who has cancer is often totally unaware of having the disorder and is not ill until after many years of growth of the tumour, during which time it has caused no symptoms. The term illness implies discomfort or inability to function optimally. Hence it is a subjective state of lack of well-being produced by disease. Regrettably, many diseases escape detection and possible cure because they remain symptomless for long years before they produce discomfort or impair function.

Illness and disease

Disease, which can be defined at the simplest level as any deviation from normal form and function, may either be associated with illness or be latent. In the latter circumstance, the disease will either become apparent at some later time or will render the individual more susceptible to illness. The person who fractures an ankle has an injury—a disease—producing immediate illness. Both form and function have been impaired. The illness occurred at the instant of the development of the injury or disease. The child who is infected with measles, on the other hand, does not become ill until approximately 10 days after exposure (the incubation period). During this incubation period the child is not ill but has a viral infectious disease that is incubating and will soon produce discomfort and illness. Some diseases render a person more susceptible to illness only when the person is under stress. Some diseases may consist of only extremely subtle defects in cells that render the cells more susceptible to injury in certain situations. The blood disease known as sickle cell anemia, for example, results from a hereditary abnormality in the production of the red oxygen-carrying pigment (hemoglobin) of the red cells of the blood. The child of a mother and father who both have sickle cell anemia will probably inherit an overt form of sickle cell anemia and will have the same disease as the parents. If only one parent has sickle cell anemia, however, the child may inherit only a tendency to sickle cell anemia. This tendency is referred to by physicians as the sickle cell trait. Individuals having such a trait are not anemic but have a greater likelihood of developing such a disease. When they climb a mountain and are exposed to lower levels of oxygen in the air, red blood cells are destroyed and anemia develops. This can serve as an example of a disease or a disease trait that renders the affected person more susceptible to illness.

Disease, defined as any deviation from normal form and function, may be trivial if the deviation is minimal. A minor skin infection might be considered trivial, for example. On the eyelid, however, such an infection could produce considerable discomfort or illness. Any departure from the state of health, then, is a disease, whether health be measured in the theoretical terms of normal measured values or in the more pragmatic terms of ability to function effectively in harmony with one's environment.

Maintenance of health

Health is not a static condition but represents a fluid range of physical and emotional well-being continually subjected to internal and external challenges such as worry, overwork, varying external temperatures, mechanical stresses, and infectious agents. These constantly changing conditions require the adjustment of the function of the various systems within the body. Mechanisms are continually at work to maintain a constant internal environment called by the French scientist Claude Bernard the *milieu intérieur*.

Definition of homeostasis

The maintenance of this relatively constant internal environment is known as homeostasis. On a hot summer day, for example, the body is challenged to maintain its normal temperature of 98.6° F (37° C). Sweating represents a mechanism by which the skin is kept moist. By the evaporation of the moisture, heat is lost more rapidly. The hot day, therefore, represents a challenge to homeostasis. On a cold day gooseflesh may develop, an example of a homeostatic response that is a throwback to mechanisms in lower animals.

Bacteria, viruses, and other microbiological agents are obvious challenges to health. The body is able, to a considerable extent, to protect itself and adjust to challenges, and, to the extent that it is successful, the state of health is maintained. While health is often thought of as fragile and subject to many onslaughts, it is, in fact, a ruggedly guarded state protected by a host of highly efficient internal mechanisms.

Some of the mechanisms vital to the maintenance of health include (1) the maintenance of the internal environment, or homeostasis, (2) adaptation to stress situations, (3) defense against microbiological agents, such as bacteria and viruses, (4) repair and regeneration of damaged tissue or cells, and (5) clotting of the blood to prevent excessive bleeding. Each of these areas will be discussed briefly. Despite these separate considerations, the commonality of purpose—the preservation and maintenance of health—must not be lost sight of. Insofar as each of these mechanisms works to maintain a constant internal environment, it can be considered as a homeostatic mechanism. Later, when disease is discussed, it will be apparent that to a considerable extent disease represents a failure of homeostasis and the other defensive responses listed above.

HOMEOSTASIS

As noted earlier, the term homeostasis refers to the maintenance of the internal environment of the body within narrow and rigidly controlled limits. The major functions important in the maintenance of homeostasis are fluid and electrolyte balance, acid-base regulation, thermoregulation, and metabolic control.

Fluid and electrolyte balance. This term refers to the controlled partition of water and major chemical constituents among the cells and the extracellular fluids of the body. The human body is basically a collection of cells grouped together into organ systems and bathed in fluids, most notably the blood. The intracellular fluid is the fluid contained within cells. The extracellular fluid—the fluid outside the cells—is divided into that found within the blood and that found outside the blood; the latter fluid is known as the interstitial fluid. These fluids are not simply water but contain varying amounts of solutes (electrolytes and other bioactive molecules). An electrolyte (sodium chloride, for example) is defined as any molecule that in solution separates into its ionic components and is capable of conducting an electric current. Cations are electrolytes that migrate toward the negative pole of an electric field; anions migrate toward the positive pole. The electrolyte composition of the various fluid compartments is summarized in Table 1.

Intracellular and extracellular fluid

It is apparent from this table that the ionic compositions of the intracellular and extracellular fluids are significantly different. The major cation of extracellular fluid is sodium.

Table 1: Principal Electrolytes of the Body Fluids

electrolyte	extracellular fluid*	intracellular fluid†
Cations (⁺ electrical charge)		
Sodium (Na^+)	142 mEq/l‡	10 mEq/l
Potassium (K^+)	4 mEq/l	160 mEq/l
Calcium (Ca^{++})	5 mEq/l	—
Magnesium (Mg^{++})	3 mEq/l	35 mEq/l
	154 mEq/l	205 mEq/l
Anions (⁻ electrical charge)		
Chloride (Cl^-)	103 mEq/l	2 mEq/l
Bicarbonate (HCO_3^-)	27 mEq/l	8 mEq/l
Phosphate (PO_4^{3-})	2 mEq/l	140 mEq/l
Sulfate (SO_4^{2-})	1 mEq/l	—
Protein	16 mEq/l	55 mEq/l
Organic acid	5 mEq/l	—
	154 mEq/l	205 mEq/l

*Approximate values in the blood plasma. †Approximate values for the muscle cells. ‡mEq/l = milliequivalents per litre.

The major anion of the extracellular fluid is chloride, while bicarbonate is the second most important. In contrast, the major cation of the intracellular fluid is potassium, and the major anions are proteins and organic phosphates. The marked differences in sodium and potassium concentrations between the intracellular and extracellular fluid of cells are not fortuitous but are due to active transport by energy-dependent ion pumps located in cell membranes. The pumps continuously move sodium ions out of the cell and potassium ions into the cell. The intracellular and extracellular compartments are thus closely integrated and interdependent: changes in one have immediate effects on the other. In clinical medicine most measurements of electrolyte concentration are performed on the extracellular fluid compartment, notably the blood serum. The values given in Table 1 remain fairly constant on a day-to-day basis, in spite of various dietary intakes of food and water.

It is the primary task of the kidneys to regulate the various ionic concentrations of the body. Any abnormality in these concentrations can produce serious disease; for instance, the normal sodium concentration in the serum (the blood minus its cells and clotting factors) ranges from 136 to 142 milliequivalents per litre, while the normal potassium level in the serum is kept within the narrow range of 3.5 to 5 milliequivalents per litre. A rise in the serum potassium to perhaps 6.2 milliequivalents per litre, as can occur when large numbers of cells are severely injured or die and potassium ions are released, could cause serious abnormalities in the performance of the heart by disturbing the regularity of the nervous impulses that maintain the heart's rhythm.

The state of hydration

The total amount of body water is also maintained at fairly constant levels from day to day by the combined action of the central nervous system and the kidneys. If one were to refrain from drinking any water for a few days, the thirst centre, located in the hypothalamus deep within the brain, would send out messages that would be translated into the feeling of thirst. At the same time a hormone from the posterior pituitary gland known as antidiuretic hormone (ADH; vasopressin) would be secreted. This hormone, released into the bloodstream, would reach the kidneys, where it would signal the kidneys to retain water and not excrete it. Should too much water be ingested, ADH secretion would be turned off, and the kidneys would promptly excrete the excess amount.

Acid-base equilibrium. The acidity of the body fluids is maintained within narrow limits. This acidity is expressed in terms of the pH of a solution, values exceeding 7 representing alkalinity and less than 7 acidity. The pH of a solution is an expression of the amount of hydrogen ion present. Increases in hydrogen ion concentration cause a lowering of the pH, and, conversely, decreases in the hydrogen ion concentration raise the pH. Any abnormal process raising the hydrogen ion concentration in the body fluids produces a state of disease referred to as acidosis; one that causes the concentration to be lowered results in alkalosis.

In health the blood is slightly alkaline, being kept at a pH of 7.35 to 7.45, a narrow range which must be maintained for the optimum operation of the many chemical reactions that go on constantly in the body. Alterations in the blood pH occur in many diseases, particularly of the lungs and kidneys, organs whose functions include regulation of the body pH.

Thermoregulation. As has been said above, the temperature of the body is kept nearly constant at 98.6° F (37° C). Fluctuations within a few tenths of a degree are perfectly compatible with health. Wider swings in temperature are usually indicative of disease, and thus body temperature is an important factor in assessing health. Body temperature is regulated by a thermostatic control centre in the hypothalamus. A rise in body temperature initiates a chain of events leading to an increase in the rate of breathing and in sweating, two processes that serve to lower the body temperature. Similarly, a decrease in body temperature, perhaps occasioned by a chilly winter walk, leads to increased heat-producing activity such as the muscular contractions of shivering—again mediated by the thermostatic control centre in the hypothalamus.

Metabolic control. In essence, metabolism involves all the physical and chemical processes by which cells are produced and maintained. Included under this broad umbrella are the regulation of fluid and electrolytes, the maintenance of plasma protein levels adequate for the building and repair of cells, and control of the amounts of sugar (glucose) and fats (lipids) in the blood so as to provide sufficient amounts for all the energy-producing activities of the cells. (The main treatment of this subject is contained in the article METABOLISM.)

Blood glucose level

The control of blood glucose levels is a good example of homeostasis. Most of the glucose utilized by the body is derived from the dietary intake of various forms of sugars and starches. These are digested within the intestinal tract into the simplest forms of carbohydrate (monosaccharides). Glucose, galactose, and fructose are the principal monosaccharides. These are absorbed from the intestines into the blood and enter the liver. Here all are eventually converted to glucose. The glucose may be utilized by the liver cells in part as a source of readily available energy, or it may be polymerized and stored as glycogen, but most of it enters the general circulation of the body and contributes to the blood glucose level. Blood glucose may also be derived in times of need by the conversion of the stored glycogen into glucose.

When food is eaten, there is a temporary rise in the blood glucose level known as alimentary hyperglycemia (high blood glucose level). Mechanisms are activated that stimulate the pancreas to secrete the hormone insulin. This hormone makes it possible for cells to utilize the glucose by facilitating its transport (carriage) across the membranes of cells into their interior, where it can enter the complex chemical reactions that provide the cell with energy. By virtue of insulin secretion, the cells receive adequate amounts of glucose, and the blood glucose levels are returned to the normal range, somewhere between 70 and 110 milligrams per 100 millilitres of blood.

ADAPTATION

Adaptation refers to the ability of cells to adjust to severe stresses and achieve altered states of equilibrium while preserving a healthy state. In the human body the large bulging muscles of an individual engaged in heavy labour are a good example of cellular adaptation. Because of the heavy demand for work from these muscles, each of the individual muscle cells within the labourer's arms and legs becomes larger (hypertrophic). This enlargement is caused by the formation of increased numbers of tiny fibres (myofilaments) that provide the contractile power of muscles. Thus, while the normal muscle cell might have 2,000 myofilaments, the hypertrophied cell might have 4,000 myofilaments. The workload can now be divided evenly among twice as many myofilaments, and the muscle cell is capable of more work. The cells are completely normal and, in fact, are more robust than their fragile cousins. The individual can do heavy work all day without excessive fatigue, and no cell injury results from the heavy workload. A new level of equilibrium has been achieved by the process of cellular hypertrophy. A person with this type of muscular development can be considered to be in excellent physical condition, capable of meeting emergency situations such as running from a fire or catching a train without the dangers that might be encountered by a person who has not undergone such a development.

The enlarged muscle cell

Inhabitants of high altitudes adapt to the lowered amounts of oxygen within the air by developing an increased number of red blood cells (a condition called secondary polycythemia). The greater number of red cells in the blood are capable of absorbing more oxygen from the air breathed into the lungs, and thus the person who lives in high altitudes makes better use of the slender oxygen content of the air.

Thus, adaptation is a mechanism by which the body preserves and maintains its health by adjusting to alterations in the conditions under which it functions.

DEFENSE AGAINST BIOTIC INVASION

Human beings are surrounded by a microscopic menagerie of organisms, most of which pose no threat and some

of which are beneficial. Organisms capable of producing disease are pathogens. The maintenance of health requires defense against biotic invasion. There are four levels of defense in the body: (1) the intact skin and linings of the various orifices of the body (such as the mouth, nose, throat), (2) a widely dispersed system of cells capable of destroying invaders, (3) the capability of mounting an inflammatory reaction that destroys offenders, and (4) the capability of developing an immune response that helps to bring about further neutralization and destroy any attackers.

Four levels of defense

Maintenance of the integrity of skin and mucosal linings. With rare exception, pathogenic organisms cannot penetrate the intact covering and linings of the body. Indeed, if one were to take samples of the bacteria found on the skin, one would find large numbers of potentially harmful organisms that represent no threat unless the skin is punctured or the linings of the body are in some way injured. There are exceptions to this generalization, and a few biotic agents probably can penetrate intact mucosal surfaces. The bacterium *Salmonella typhi* that causes typhoid fever is thought to penetrate the normal lining of the gastrointestinal tract. Nevertheless, the intact skin and mucosal linings are primary protective barriers in the maintenance of health. The skin serves as a barrier to the external world, and the mucus-secreting and ciliated membranes of the upper respiratory tract trap inhaled foreign material and bacteria, transporting them to the pharynx where they are either swallowed or expelled by coughing. Potentially harmful bacteria can be introduced into a cut, which thus provides a portal of entry for organisms that may then cause an infection. By adequate washing, at least sufficient numbers of bacteria are flushed out to prevent the infection. Irritation of the skin from any cause or irritation of the throat by habitual smoking of tobacco impairs the integrity of these barriers and predisposes the area to invasion by potentially harmful organisms. The body has ingeniously contrived to place further roadblocks in the way of invaders. The saliva and the secretions in the stomach, for example, contain enzymes and acids that also destroy most organisms. Thus, humans have an effective enclosing barrier that provides protection against biotic attack.

Phagocytic cells of the body. Phagocytosis is the process by which certain cells ingest particulate material. When a phagocytic cell comes in contact with some particle such as a bacterium or even inert material such as dust, the cytoplasm of the cell (the cell substance outside its nucleus) flows around the object and forms a phagocytic vesicle. The phagocytic vesicle containing the particle then fuses with a lysosome (a membrane-enclosed sac that contains digestive enzymes). If the chemical composition of the foreign substance permits its degradation by the enzymes, it is destroyed. If the ingested material is resistant to digestion, it is retained within the phagocyte and is thus effectively removed from further interaction with the host. Phagocytic cells abound in the body; they serve as a second line of defense against most biotic invasion.

There are two groups of phagocytic cells, white blood cells—polymorphonuclear leukocytes—and tissue cells. The white blood cells are able to migrate through blood-vessel walls in areas of inflammation or infection, where they may phagocytize foreign material such as bacteria. Moreover, in inflammatory and infectious states, the total number of white cells in the body increases (leukocytosis). Thus the population of phagocytic cells is expanded when the cells are needed in the body's defense.

The second group of phagocytes consists of cells that are usually firmly fixed within tissues and are known as the reticuloendothelial system. The cells in this system are designated by a variety of names depending on their location (*e.g.,* Kupffer cells in the liver, macrophages or histiocytes in loose connective tissue). They are particularly abundant in the spleen, liver, lymph nodes, and bone marrow but are also scattered throughout the blood vessels and virtually all the other tissues of the body. If, for example, bacteria do find a portal of entry but the bacterial invasion is not too massive and the organisms are not too virulent, these phagocytic cells are capable of engulfing and destroying them before they can cause injury.

The inflammatory response. Whenever cells are damaged or destroyed, a series of vascular and cellular events known as the inflammatory response is set in motion. This response is protective of health in that it destroys or walls off injurious influences and paves the way for the restoration of normality. The sequence of events is as follows: in an area of injury (as in a bacterial infection), cells release substances that cause the small blood vessels in the affected area to become dilated (vasodilation) and thus increase the blood flow to the injured area; at the same time, clear fluid leaks out of the vessels into the area; this fluid tends to dilute any harmful substances in the area of injury; next, white cells from the blood flow out of the blood vessels into the damaged area and phagocytize the bacteria and dead cells; the resulting mixture of dead cellular debris and white blood cells is known as pus.

The major signs of inflammation are redness and increased heat (caused by blood-vessel dilation), swelling (resulting from the accumulation of fluid), and pain. The last of these is one of the cardinal signs of all inflammatory responses. Pain in inflammation is caused by substances released by damaged tissues that render local nerve endings more sensitive to stimulation. Inflammation can be classified as either acute or chronic. Acute inflammation, such as may be seen around a skin cut, lasts for only a few days and is characterized microscopically by the presence of polymorphonuclear leukocytes. Chronic inflammation is of longer duration and is characterized microscopically by the presence of lymphocytes, monocytes, and plasma cells and, in general, is associated with little fluid exudation.

Major signs of inflammation

Because of the pain and swelling, the inflammatory response is often viewed as an unwelcome event following injury. Yet it is important to recognize that it is the first step in the healing process and represents an important protective response in the maintenance of health.

The immune response. The immune reaction is one of the most important defense mechanisms against biotic invasion and is therefore vital to the preservation of health. The devastating effects of acquired immune deficiency syndrome (AIDS) and other conditions that suppress or destroy the immune system are cases in point (see below *The causes of disease: Diseases of immune origin*).

The immune response is a relatively recent evolutionary development found only in vertebrates. This complex system has multiple components, which include antigens, antibodies, complement, and various types of white blood cells such as B and T lymphocytes. The interaction of these components collectively results in a reaction that serves to protect the host from the potentially adverse effects of infectious organisms. Antigens are proteins, polysaccharides (complex carbohydrates), or foreign substances that trigger an immune response; they include molecules that are important constituents of bacteria, viruses, and fungi and substances that mark the surfaces of foreign materials such as pollen or transplanted tissue. Antibodies, or immunoglobulins, are proteins raised against specific antigens; they are formed in the lymph nodes and bone marrow by mature B lymphocytes called plasma cells and are released into circulation to bind and neutralize antigens located throughout the body. This type of response, called humoral immunity, is active mainly against toxins and free pathogens (those not ingested by phagocytes) in body fluids. A second type of response, called cell-mediated immunity, does not yield antibodies but instead generates T lymphocytes that are reactive against specific antigens. This defense is exhibited against bacteria and viruses that have been taken up by the host's cell as well as against fungi, transplanted tissue, and cancer cells. In each case the immune response prevents the invaders from causing further damage to the host. The complement system is a group of proteins found in the blood that facilitates the immune response by both attracting phagocytes to the area of invasion and forming a complex that results in lysis of the foreign cell.

Action of complement

Two remarkable qualities of the immune system are specificity and memory. When an antigen enters the body, it elicits production of either a specific antibody or specific immunologically competent cells; that is, the antibody or the cells will neutralize only the antigen that evokes them.

Furthermore, the system exhibits what appears to be memory: once challenged by an antigen, such as the measles virus, the body "remembers" it for years and perhaps for life. The child who has an attack of measles becomes immune for life. If the child is exposed to this specific antigen at a later date, the immune system recognizes it and responds and thereby prevents a reinfection. Indeed, these two characteristics of the immune system, specificity and memory, serve as the basis for preventive immunization. Inoculation of infants or children with inactivated or attenuated biotic agents will cause the immune system to be made alert to such an antigen should it appear at a later date. Poliomyelitis, for example, once dreaded as a cause of paralysis and death, has been effectively controlled if not abolished with the polio vaccine.

Thus, the immune system is a vital part of the defense against biotic invasion. However, if it malfunctions, the immune system may also cause disease.

REPAIR AND REGENERATION

By replacing damaged or destroyed cells with healthy new cells, the processes of repair and regeneration work to restore an individual's health after injury. Unlike the salamander, which is capable of regenerating a limb if it is lost, human beings cannot regenerate whole organs or limbs. If one kidney is destroyed by disease, it is permanently lost. However, the remaining contralateral kidney, if normal, is capable of limited regeneration to compensate for the decrease in kidney mass. The many cell types of the body have varying capacities for regeneration.

Regeneration

Regeneration is the production of new cells exactly like those destroyed. Of the three categories of human cells—(1) the labile cells, which multiply throughout life, (2) the stable cells, which do not multiply continuously but can do so when necessary, and (3) the permanent cells, incapable of multiplication in the adult—only the permanent cells are incapable of regeneration. These are the brain cells and the cells of the skeletal and heart muscles.

Labile cells are those of the bone marrow, the lymphoid tissues, the skin, and the linings of most ducts and hollow organs of the body.

Stable cells are found in the liver, in many of the glands of the body, such as the pancreas and salivary glands, in the lining of the kidney tubules, and in the connective tissues. Normally these cells do not divide unless some are destroyed by disease or injury and must be replaced.

If only a small area of the liver (made up of stable cells) is damaged or destroyed, unaffected cells around the area of injury can replace those that were lost. When large areas of the liver are destroyed, however, cellular regeneration cannot occur, and the area of cell loss is replaced by new healthy connective-tissue cells, which produce scars. If a heart attack occurs, a certain number of heart muscle cells (permanent cells) are killed because of loss of blood supply. Because heart muscle cells cannot regenerate, the area of injury is replaced by a scar (if the patient survives). Such repair is by no means perfect, but it nonetheless permits restoration of reasonable heart function with perhaps only a slightly reduced level of health, depending on the number of heart muscle cells that have been lost.

Cellular regeneration in humans is limited by many other factors, such as the availability of blood supply and a supporting connective tissue. When the blood vessels and supporting cells (connective tissue) are destroyed in the liver along with the liver cells, perfect reconstitution of the liver is not possible. There may be some regrowth of liver cells, but they do not form the normal liver architecture, and the newly regenerated cells cannot function because they do not have an appropriate orientation to the blood vessels and bile ducts.

HEMOSTASIS

Another mechanism of defense is hemostasis, the prevention of loss of blood from damaged blood vessels by formation of a clot. (This process is covered more at length in the article BLOOD: *Bleeding and blood clotting*.) Simply stated, a break in a blood vessel leads to activation of a complex sequence of events that results in the formation of a solid plug of platelets, red blood cells, and fibrin (a fibrous protein formed from fibrinogen). This plug, or clot, seals the damaged vessel and prevents further loss of blood (hemorrhage). The numerous components of the blood called clotting factors contribute in sequential fashion to the formation of the clot. (The clotting factors are commonly referred to by a roman numeral rather than by name. Fibrinogen, for example, is clotting factor I.) A defect in one of these factors can undermine hemostasis; for example, the absence of clotting factor VIII leads to hemophilia A, a disorder of uncontrolled bleeding.

INTERRELATIONSHIP OF DEFENSIVE MECHANISMS

The homeostatic and defensive mechanisms involved in maintaining a constant internal environment are complex and yet wonderfully coordinated. Thus, the normal state of health is not a static condition but exists rather within a narrow range maintained by the coordinated responses of many systems and mechanisms. Health requires the proper function of all these controls. Disease may begin in a single organ or system, but the interdependence and close coordination of the many bodily functions, which cooperate so beautifully in health, may be upset by a chain reaction when one breaks down. A disease of the kidney leading to abnormal retention of sodium, for example, can cause hypertension (high blood pressure). Prolonged hypertension in turn can induce heart failure, and this can result in the abnormal collection of fluid in the lungs. The impairment of respiratory function may then result in a sudden rise in the level of carbon dioxide in the blood, which brings with it further complications. Similarly, if the normal inflammatory response malfunctions, a trivial skin infection (popularly known as a pimple) can enlarge into a boil (a furuncle). The responsible bacterial agents may proliferate in the local site and penetrate small blood vessels to seed the bloodstream, thus causing a generalized infection (septicemia or bacteremia). Such a widespread infection is extremely serious and may cause secondary infections of the heart (endocarditis) or of the coverings of the brain (meningitis) and end in death of the host.

Chain reactions in disease

Thus, health implies the proper functioning of the homeostatic mechanisms that have just been described, including those systems involved in the defense of health. The state of disease basically represents a failure of these mechanisms. Although one tends to think of disease in terms of offending agents, these agents are able to produce disease only by their ability to disrupt normal homeostasis, and it is precisely those disruptions that are the manifestations of disease.

Disease: signs and symptoms

Disease may be acute, chronic, malignant, or benign. Of these terms, chronic and acute have to do with the duration of a disease, malignant and benign with its potentiality for causing death.

An acute disease process usually begins abruptly and is over soon. Acute appendicitis, for example, is characterized by the sudden onset of nausea, vomiting, and pain usually localized in the lower right side of the abdomen. It usually requires immediate surgical treatment. The term chronic refers to a process that often begins very gradually and then persists over a long period. For example, ulcerative colitis—an inflammatory condition of unknown cause that is limited to the colon—is a chronic disease. The disease is characterized by relapsing attacks of bloody diarrhea that persist for weeks to months. These attacks alternate with asymptomatic periods that can last from weeks to years.

The terms benign and malignant, most often used to describe tumours, can be used in a more general sense. Benign diseases are generally without complications, and a good prognosis (outcome) is usual. A wart on the skin is a benign tumour caused by a virus; it produces no illness and usually disappears spontaneously if given enough time (often many years). Malignancy implies a process that, if left alone, will result in fatal illness. Cancer is the general term for all malignant tumours.

Diseases usually are indicated by signs and symptoms. A sign is defined as an objective manifestation of disease that

can be determined by a physician; a symptom is subjective evidence of disease reported by the patient. Each disease entity has a constellation of signs and symptoms more or less uniquely its own; individual signs such as fever, however, may be found in a great number of diseases. Some of the common manifestations of disease—as they relate to an imbalance of normal homeostasis—are taken up in this section. They are covered more at length in the article DIAGNOSIS AND THERAPEUTICS.

Fever is an abnormal rise in body temperature. It is most often a sign of infection but can be present whenever there is tissue destruction, as, for example, from a severe burn or when large amounts of tissue have died because of lack of blood supply. Body temperature is controlled by the thermostatic centre in the hypothalamus. Certain protein and polysaccharide substances called pyrogens, released either from bacteria or viruses or from destroyed cells of the body, are capable of raising the thermostat and causing a rise in body temperature. Fever is a highly significant indicator of disease.

Increased number of white blood cells

An increase in the number of circulating phagocytic white blood cells (leukocytosis), mentioned above (see *Maintenance of health: Defense against biotic invasion: Phagocytic cells of the body*), is one of the more common manifestations of disease. The stimulus for such an event may be any inflammatory process in the body, such as is caused by bacteria, viruses, or any process that leads to the destruction of cells. Such leukocytosis is reflected in the white blood cell count, which may be substantially elevated above the normal upper value of 10,000 cells per cubic millimetre of blood.

The pulse rate is another easily obtainable and important piece of information. The heart rate varies with the level of physical activity: the heart beats faster during exercise and more slowly during rest. An inappropriate heart rate (or pulse) may be indicative of disease. The heart rate increases in the feverish patient. A weak, rapid pulse rate may be a sign of severe blood loss or of disease within the heart itself. Irregularity of the pulse (arrhythmia) is an important indicator of heart malfunction.

The respiratory rate (rate of breathing) is modified by disease. Persons with fever have an increased respiratory rate (hyperventilation), which serves to lower body temperature (this rapid breathing is analogous to the panting of a dog). Hyperventilation is a common response to painful stress. Any condition leading to acidosis (lowering of body pH) similarly drives the respiratory rate upward. Diseases of the lungs—with the accompanying inability to oxygenate the blood adequately—have a similar effect.

Temperature, pulse, and respiratory rate—called the vital signs—may be important manifestations of disease. A fourth vital sign, blood pressure, is equally significant. Among other things, it indicates the amount of blood in circulation. A decrease in circulating blood volume, as is seen with severe bleeding, lowers the blood pressure and deprives the tissues of adequate blood flow. Reflexes are initiated that compensate for the reduced blood volume and blood pressure. The heart rate increases and compensates to some extent for the sudden reduction in blood volume and pressure; at the same time, peripheral blood vessels in such areas as the abdomen constrict, tending to divert the reduced blood volume to the more vital areas such as the brain and head. Unusual elevation of pressure (hypertension) is a disease by itself.

Causes of edema

Fluid and electrolyte imbalances may be further consequences of homeostatic failure and additional significant manifestations of disease. The causes of these abnormalities are complex. Edema, or swelling, results from shifts in fluid distribution within body tissues. Edema may be localized, as when the leg veins are narrowed or obstructed by some disease process. The pressure of the blood in the distended veins rises, and fluid is driven out of the vessels into the tissues, causing swelling of the extremity. Generalized edema is seen in renal (kidney) disease that causes abnormal retention of sodium and water. Heart failure is an additional cause of generalized edema, usually most manifest as swollen feet and ankles. Alterations such as dehydration, hyperventilation, and tissue destruction can all lead to varying fluid and electrolyte derangements. The levels of the serum electrolytes (sodium, potassium, bicarbonate, chloride), determined relatively easily in the laboratory, provide the physician with valuable clues to deranged homeostasis induced by disease.

Finally, the determination of body pH and a number of blood tests designed to evaluate adequate (or inadequate) metabolic regulation provide diagnostic clues of homeostatic failure. These tests include determination of the levels of the blood glucose, blood urea nitrogen, and serum protein.

The disease diabetes mellitus provides an excellent example of failure of the homeostatic mechanisms. Diabetes is a common disease of metabolic-endocrine (ductless gland) origin involving a relative or absolute deficiency of insulin, a hormone that plays a major role in carbohydrate metabolism. Any or all of the homeostatic derangements can be found in this disease. Patients with a severe form of diabetes may at one time be dehydrated because of obligatory excretion of water (osmotic diuresis), be acidotic because of formation of increased amounts of keto acids derived from the oxidation of free fatty acids, be hyperventilating as a result of the acidosis, be comatose because of high levels of blood glucose, have a weak pulse because of severe dehydration, have electrolyte abnormalities, and so on. The signs and symptoms are numerous, all illustrating the interdependence of the homeostatic mechanisms, which, when not functioning properly, provide the manifestations of disease.

At the most elemental level, disease develops when any disruptive or adverse influence overcomes the homeostatic and defensive controls of the body. As will be seen, there are numerous influences that can tip the scales of health toward disease. Viruses and bacteria are obvious threats to health. There are a great many others, some so subtle as to be poorly understood. The following section focuses on the causes of disease rather than on a detailed description of each entity. It represents one method of classification. There is considerable overlap in categories; certain diseases grouped as metabolic-endocrine in origin could also be classified as diseases of genetic origin. Indeed, the interdependence of the organ systems, the metabolic pathways, and the defense systems renders finite classification in medicine difficult. The human body acts as a unit—an individual—both in health and in disease.

Overlap in causal categories

The causes of disease

The search for the causes (etiologies) of human diseases goes back to antiquity. Hippocrates, a Greek physician of the 4th and 5th centuries BC, is credited with being the first to adopt the concept that disease is not a visitation of the gods but rather is caused by earthly influences. Scientists have since continually searched for the causes of disease and, indeed, have discovered the causes of many.

In the development of a disease (pathogenesis) more is involved than merely exposure to a causative agent. A room full of people may be exposed to a sufferer from a common cold, but only one or two may later develop a cold. Many host factors determine whether the agent will induce disease or not. Thus, in the pathogenesis of disease, the resistance, immunity, age, and nutritional state of the person exposed, as well as virulence or toxicity of the agent and the level of exposure, all play a role in determining whether disease develops.

In the following sections the many types of human disease will be divided into categories, and in each only a few examples will be given to establish the nature of the process. These categories are divided on the basis of the presumed etiology of the disease. Many diseases are still of unknown (idiopathic) origin. With others the cause may be suspected but not yet definitively proved.

DISEASES OF GENETIC ORIGIN

Certain human diseases result from mutations in the genetic complement (genome) contained in the deoxyribonucleic acid (DNA) of chromosomes. A gene is a discrete linear sequence of nucleotide bases (molecular units) of the DNA that codes for, or directs, the synthesis of a protein, and there may be as many as 100,000 genes in the human

genome. Proteins, many of which are enzymes, carry out all cellular functions. Any alteration of the DNA may result in the defective synthesis and subsequent malfunctioning of one or more proteins. If the mutated protein is a key enzyme in normal metabolism, the error may have serious or fatal consequences. More than 5,000 distinct diseases have been ascribed to mutations that result in deficiencies of critical enzymes.

Mutations are classified on the basis of the extent of the alteration. Large mutations, which include alterations to chromosome structure and number, are relatively rare because most cause such major disruptions to development that the fetus is naturally aborted. However, certain alterations are not so immediately lethal, and the fetus can survive with a characteristic disorder. Down syndrome is one such case. It involves an error in the division of chromosome 21 that results in trisomy (three copies of a chromosome instead of two are inherited), bringing the total number of chromosomes to 47 instead of 46. Many characteristics such as distinctive facial features and mental retardation result from the presence of this extra chromosome. Smaller mutations are more common and include point mutations, in which substitution of a single nucleotide base occurs, and deletion or insertion mutations, which involve several bases. Point, deletion, and insertion mutations may cause an abnormal protein to be synthesized or may prevent the protein from being made at all.

Mutations that occur in the DNA of somatic (body) cells cannot be inherited, but they can cause congenital malformations and cancers (see below *Abnormal growth of cells*); however, mutations that occur in germ cells—*i.e.*, the gametes, ova and sperm—are transmitted to offspring and are responsible for inherited diseases. Each gamete contributes one set of chromosomes and therefore one copy (allele) of each gene to the resultant offspring. If a gene bearing a mutation is passed on, it may cause a genetic disorder.

Genetic diseases caused by a mutation in one gene are inherited in either dominant or recessive fashion. In dominantly inherited conditions, only one mutant allele, which codes for a defective protein or does not produce a protein at all, is necessary for the disorder to occur. In recessively inherited disorders, two copies of a mutant gene are necessary for the disorder to manifest; if only one copy is inherited, the offspring is not affected, but the trait may continue to be passed on to future offspring. In addition to dominant or recessive transmission, genetic disorders may be inherited in an autosomal or X-linked manner. Autosomal genes are those not located on the sex chromosomes, X and Y; X-linked genes are those located on the X chromosomes that have no complementary genes on the Y chromosome. Females have two copies of the X chromosome, but males have an X and a Y chromosome. Because males have only one copy of the X chromosome, any mutation occurring in a gene on this chromosome will be expressed in male offspring regardless of whether its behaviour is recessive or dominant in females. Autosomal dominant disorders include Huntington's chorea, a degenerative disease of the nervous system that usually does not develop until the carrier is between 30 and 40 years of age. The delayed onset of Huntington's chorea allows this lethal gene to be passed on to offspring. Autosomal recessive diseases are more common and include cystic fibrosis, Tay-Sachs disease, and sickle cell anemia. X-linked dominant disorders are rare, but X-linked recessive diseases are relatively common and include Duchenne's muscular dystrophy and hemophilia A.

Congenital genetic disorders

Most genetic disorders can be detected at birth because the child is born with characteristic defects. Thus these abnormalities are congenital (existing at birth) genetic disorders. A few genetic defects, such as Huntington's chorea mentioned above, do not become manifest until later in life. Hence it may be said that most but not all genetic diseases are congenital.

Conversely, some congenital diseases are not genetic in origin; instead they may arise from some direct injury to the developing fetus. If a woman contracts the viral disease German measles (rubella) during pregnancy, the virus may infect the fetus and alter its normal development, leading to some malformations, principally of the heart. These malformations constitute a congenital disease that is not genetic.

Further confusion often arises over the terms genetic and familial. A familial disease is hereditary, passed on from one generation to the next. It resides in a genetic mutation that is transmitted by mother or father (or both) through the gametes to their offspring. Not all genetic disorders are familial, however, because the mutation may arise for the first time during the formation of the gametes or during the early development of the fetus. Such an infant will have some genetic abnormality, though the parents themselves do not. Down syndrome is an example of a genetic disease that is not familial.

Factors relating to genetic injury. The causes of mutations are still poorly understood. Certain factors, however, are thought to be important. Maternal age plays an important role in predisposing toward genetic injury. The frequency of Down syndrome and of congenital malformations increases with the age of the mother. This may be so for a variety of reasons. Unlike men, who produce new sperm continually, women are born with all the eggs (ova) they will ever have. Thus the eggs are exposed to the same internal and external agents that the woman comes in contact with. The longer the exposure to such factors (*i.e.*, the older the mother), the greater the chance of genetic injury to the ova. A paternal contribution to the disease also has been discovered—roughly 25 percent of cases may be caused by extra chromosomal material from the father. At present, the nature of the factors responsible for impaired division of chromosomes remains unknown.

Congenital defects and age of mother

Radiation is a well-recognized cause of chromosomal damage. The survivors of the atomic bomb blasts in Japan in 1945 have shown definite chromosomal abnormalities in certain types of their circulating white blood cells. Indeed, a higher incidence of leukemia (a form of cancer of white cells), as well as other cancers, has been reported in this population, suggesting that the chromosomal changes may have played some role in the induction of the disease (see also RADIATION: *Biologic effects of ionizing radiation*).

Viruses have been shown to cause mutations in human cells when the cells are grown in tissue culture, but there is no clear evidence that viral infections can cause genetic injury in humans. Instead, current evidence suggests that the oncogenic viruses implicated in some human cancers facilitate genetic mutations rather than cause them directly.

The induction of DNA mutations in cells by drugs and chemicals is complex. It involves metabolism of the drug by detoxification enzymes into reactive intermediates that damage DNA. The mutations that remain are those not removed by DNA repair enzymes. In contrast to viruses, drugs and chemicals have been shown to cause mutations not only in human cells in culture but also in a living host.

Heredity and environment. Diseases can be spread across a wide spectrum, with predominantly genetic diseases at one extreme of the spectrum and diseases of largely environmental origin at the other. In the genetic part of the spectrum are diseases such as Turner's syndrome; in the environmental part are infectious diseases and chemical poisoning. Between these two extremes lie most human diseases—those with both genetic and environmental causative influences that are significant. Indeed, even at the very extreme ends of the spectrum both factors play some role. The genetic constitution dictates in part the host's response to environmental challenges. Similarly, environmental factors play significant roles in the manifestation of genetically induced disease. Sickle cell anemia, for example, an inherited disease characterized by abnormal red blood cells and hemoglobin, is seriously exacerbated by low levels of oxygen in the air.

Familial tendencies to disease

Furthermore, there are many disorders in which there is a familial tendency to develop the disease but no formal pattern of inheritance has been delineated. Many forms of cancer, high blood pressure, arthritis, and obesity, for example, seem to have a familial tendency. Although the exact roles of environmental and genetic factors are unknown in all these diseases, it is strongly felt that both factors contribute to the disease process.

CHEMICAL AND PHYSICAL INJURY

Chemical injury: poisoning. A poison is any substance that can cause illness or death when ingested in small quantities. This definition excludes the multitude of substances that cause damage if ingested in large quantities. For example, even oxygen and glucose, so crucial to life, are toxic to cells when administered at high concentrations.

There are several considerations to keep in mind when one discusses poisoning. The first of these, as already suggested, is the degree of toxicity. A substance with a very high toxicity (such as cyanide) need be taken only in minute amounts to cause serious harm or death.

A second consideration is the mechanism by which a poison operates. Each poison acts at particular sites in the cell that are critical for the maintenance of homeostasis. These sites include the genome, whose expression dictates cell structure and function, and the cell membrane, which regulates ion transport, energy metabolism, and synthesis of vital proteins. Each poison also has a characteristic ability to cause damage at particular sites within the body, such as the liver, kidneys, or central nervous system.

A third factor is the body's ability to eliminate the substance. Some chemicals, rapidly excreted in the urine, must act quickly while they remain transiently in the body. Others are poorly eliminated, and, because of this, a chronic ingestion of nontoxic amounts leads to a buildup in the body that can reach toxic levels. Lead poisoning is a good example of this phenomenon.

The route of entry is also important. Many substances are harmless when eaten but become deadly if injected into a vein. There are chemicals and drugs that are highly reactive and interact directly with an important cellular component to cause cell injury or death. Other chemicals or drugs that are not toxic per se become so following their metabolic conversion to toxic intermediates by the host. Similarly, the chemical form of a substance affects its action on the body. Metallic mercury, as found in thermometers, is harmlessly excreted, whereas the chloride salt of the same substance is deadly.

Finally, the condition of the host, the recipient of the poison, is an important consideration. A dose of aspirin (acetylsalicylic acid) that is harmless to an adult may be poisonous to an infant. Similarly, an elderly person's tolerance of a substance may be much lower than that of a healthy young adult.

A wide variety of poisons exist, among which a few stand out as being the most commonly encountered in medical practice. Some are of relatively low toxicity but are important because of their widespread use. Many physicians consider aspirin the most dangerous poison because of its commonplace use and abuse and because it is the leading cause of poisoning in children. In the following paragraphs three groups of agents will be presented: (1) organic chemicals, (2) inorganic chemicals, and (3) drugs.

Organic chemicals. Among the organic chemicals commonly encountered in instances of poisoning are two forms of alcohol, ethyl alcohol (ethanol) and methyl alcohol (methanol). Ethyl alcohol is the form found in most alcoholic beverages. Methyl alcohol, or wood alcohol, is used for a variety of household purposes.

Ethyl alcohol poisoning

Acute ethyl alcohol poisoning is encountered after ingestion of large quantities over a relatively short time. The alcohol is quickly absorbed from the gastrointestinal tract, and high blood levels can be achieved in a remarkably short time. Ethyl alcohol acts principally as a central-nervous-system depressant and, fortunately, stupor usually results before fatal doses can be reached. The difference in blood levels between intoxication and fatal stupor is very slight, however, and death may result with the ingestion of large quantities of alcohol from depression of the respiratory centre in the brain.

Carbon monoxide is a nonirritating, inert gas without colour, taste, or odour. A poison responsible for a large number of accidental and suicidal deaths, it is one of the chemical products of any combustion of organic material. Inhalation of a 1 percent concentration can be fatal within 10 to 20 minutes. Carbon monoxide acts as an internal asphyxiant causing oxygen starvation of tissues. It should be noted that exposure to even low concentrations can result in the slow accumulation of this poison over hours, days, or weeks, leading very gradually to toxic or fatal levels.

Inorganic chemicals. The inorganic chemicals most commonly responsible for poisonings in the United States are cyanide, mercury, arsenic, and lead. While the last three often appear in chemical forms that are quite harmless, it is the soluble salts of the substances that are poisons.

Cyanide poisoning

Cyanide is a dangerous substance in any form. It may occur in the form of hydrocyanic gas or as solid compounds such as potassium cyanide. It is one of the most lethal poisons known; an amount of 0.2 gram (0.007 ounce) administered to a 70-kilogram (154-pound) human causes death within minutes. Like carbon monoxide, it acts as a cellular asphyxiant.

Mercury in the pure metallic form is rather harmless, but the salt of the same substance, notably mercuric chloride, is a deadly poison. As little as 0.1 gram is enough to cause damage to body tissues, and 2 grams can cause death in a 70-kilogram person. This agent causes extensive tissue damage wherever high concentrations of the poison are encountered. When the substance is swallowed, the stomach represents the portal of entry. The mercuric chloride is partially absorbed into the blood, and this portion is excreted through the urine. The remainder affects organs in the digestive tract, principally the stomach and the colon, and the kidneys. Mercuric salts cause death of cells by precipitating the proteins within the cells, a form of cell injury called coagulative necrosis. With careful treatment, affected persons survive with full recovery. Chronic ingestion of smaller amounts of mercuric salts, as is seen in some industrial settings, can result in disease involving the mouth, skin, and nervous system.

Arsenic is contained in many items used around the house. Both odourless and tasteless compounds of arsenic are found in some rat poisons, plant sprays, paints, and other household preparations. Many of these household staples are ingested accidentally by children. Principally affected by arsenic are the blood vessels and the central nervous system; vascular collapse and depression of the central nervous system can be followed by coma and death within hours after ingestion.

Lead salts

The soluble salts of inorganic lead are also strong systemic poisons. They may accumulate within the body over a long period until toxic levels are reached and cell damage ensues. These salts were at one time commonly found in paints, and lead poisoning was frequently seen in children who chewed on their painted cribs or woodwork. Legislation in many countries has outlawed the use of lead-base paints for infants' furniture. Other forms of poisoning are incurred through industrial exposure and ingestion of water from lead pipes. Lead poisoning damages red blood cells and leads to hemolysis (rupturing of red blood cells) with resulting anemia. In the brain, lead accumulation causes the degeneration of nerve cells. This produces such manifestations as mental depression, psychoses, convulsions, and even coma and death. If an early fatality does not occur, the lead is slowly excreted and complete recovery may be anticipated.

Drugs. Drugs are another important cause of poisoning. It is a pharmacological principle that, for any therapeutic gain derived from a drug, a price is paid. There are few drugs used today that have no side effects (*i.e.*, effects unintended when the drug is administered). Although these side effects may be harmless and inconsequential, certain drugs have side effects that are potent. Similarly, a drug may be useful in a certain dose range but harmful when larger doses are taken. Morphine, for example, is an excellent drug for the control of severe pain, but it can depress respiration, and too much of it can cause death. All drugs are, therefore, potentially harmful.

Barbiturates and salicylates are the major drugs commonly found to cause serious illness from overingestion. Barbiturates affect the central nervous system almost exclusively. With toxic levels, the vital centres located within the midbrain are depressed; this leads to profound coma, depression of respiration, oxygen starvation of the tissues, and even shock. The identification of barbiturate poisoning relies almost exclusively on finding the substance in the blood or urine, because there is little anatomic change

in tissues. Treatment is directed toward getting the drug out of the system as quickly as possible, either by inducing copious urinary excretion of the drug or by the use of the artificial kidney—a process called hemodialysis.

Aspirin

Aspirin, or acetylsalicylic acid, is a drug that deserves special mention because it is such a common household item and often within the reach of small children. Approximately 10 to 30 grams of aspirin can be fatal in adults, and much smaller amounts can be fatal in children. (A single aspirin tablet of standard size contains approximately one-third gram.) There are many signs and symptoms associated with salicylate poisoning, including headaches, drowsiness, dyspepsia, nausea, vomiting, sweating, and thirst. Salicylate poisoning is an acute medical emergency. Rigorous medical treatment is demanded, and use of the artificial kidney is often required.

Physical injury. Physical injuries include those caused by mechanical trauma, heat and cold, electrical discharges, changes in pressure, and radiation. Mechanical trauma is an injury to any portion of the body from a blow, crush, cut, or penetrating wound. The complications of mechanical trauma are usually related to fracture, hemorrhage, and infection. They do not necessarily have to appear immediately after occurrence of the injury. Slow internal bleeding may remain masked for days and lead to an eventual emergency. Similarly, wound infection and even systemic infection are rarely detectable until many days after the damage. All significant mechanical injuries must therefore be kept under observation for days or even weeks.

Injuries from cold or heat. Among physical injuries are injuries caused by cold or heat. Prolonged exposure of tissue to freezing temperatures causes tissue damage known as frostbite. Several factors predispose to frostbite, such as malnutrition leading to a loss of the fatty layer under the skin, lack of adequate clothing, and any type of insufficiency of the peripheral blood vessels, all of which increase the loss of body heat.

When the entire body is exposed to low temperatures over a long period, the result can be alarming. At first blood is diverted from the skin to deeper areas of the body, resulting in anoxia (lack of oxygen) and damage to the skin and the tissues under the skin, including the walls of the small vessels. This damage to the small blood vessels leads to swelling of the tissues beneath the skin as fluid seeps out of the vessels. When the exposure is prolonged, it leads eventually to cooling of the blood itself. Once this has occurred, the results are catastrophic. All the vital organs become affected, and death usually ensues.

Three categories of burns

Burns may be divided into three categories depending on severity. A first-degree burn is the least destructive and affects the most superficial layer of skin, the epidermis. Sunburn is an example of a first-degree burn. The symptoms are pain and some swelling. A second-degree burn is a deeper and hence more severe injury. It is characterized by blistering and often considerable edema (swelling). A third-degree burn is extremely serious; the entire thickness of the skin is destroyed, along with deeper structures such as muscles. Because the nerve endings are destroyed in such burns, the wound is surprisingly painless in the areas of worst involvement.

The outlook in burn injuries is dependent on the age of the victim and the percent of total body area affected. Loss of fluid and electrolytes and infection associated with loss of skin provide the major causes of burn mortality.

Electrical injuries. The injurious effects of an electrical current passing through the body are determined by its voltage, its amperage, and the resistance of the tissues in the pathway of the current. It must be emphasized that exposure to electricity can be harmful only if there is a contact point of entry and a discharge point through which the current leaves the body. If the body is well insulated against such passage, at the point of either entry or discharge, no current flows and no injury results. The voltage of current refers to its electromotive force, the amperage to its intensity. With high-voltage discharges, such as are encountered when an individual is struck by lightning, the major effect is to disrupt nervous impulses; death is usually caused by interruption of the regulatory impulses of the heart. In low-voltage currents, such as are more likely to be encountered in accidental exposure to house or industrial currents, death is more often due to the stimulation of nerve pathways that cause sustained contractions of muscles and may in this way block respiration. If the electrical shock does not produce immediate death, serious illness may result from the damage incurred by organs in the pathway of the electrical current passing through the body.

Pressure-change injuries. Physical injuries from pressure change are of two general types: (1) blast injury and (2) the effects of too-rapid changes in the atmospheric pressure in the environment. Blast injuries may be transmitted through air or water; their effect depends on the area of the body exposed to the blast. If it is an air blast, the entire body is subject to the strong wave of compression, which is followed immediately by a wave of lowered pressure. In effect the body is first violently squeezed and then suddenly overexpanded as the pressure waves move beyond the body. The chest or abdomen may suffer injuries from the compression, but it is the negative pressure following the wave that induces most of the damage, since overexpansion leads to rupture of the lungs and of other internal organs, particularly the intestines. If the blast injury is transmitted through water, the victim is usually floating, and only that part of the body underwater is exposed. An individual floating on the surface of the water may simply be popped out of the water like a cork and totally escape injury.

Blast injuries

Decompression sickness is a disease caused by a too-rapid reduction in atmospheric pressure. Underwater divers, pilots of unpressurized aircraft, and persons who work underwater or below the surface of the Earth are subject to this disorder. As the atmospheric pressure lessens, dissolved gases in the tissues come out of solution. If this occurs slowly, the gases diffuse into the bloodstream and are eventually expelled from the body; if this occurs too quickly, bubbles will form in the tissues and blood. The oxygen in these bubbles is rapidly dissolved, but the nitrogen, which is a significant component of air, is less soluble and persists as bubbles of gas that block small blood vessels. Affected individuals suffer excruciating pain, principally in the muscles, which causes them to bend over in agony—hence the term "bends" used to describe this disorder.

Radiation injury. Radiation can result in both beneficial and dangerous biological effects. There are basically two forms of radiation: particulate, composed of very fast-moving particles (alpha and beta particles, neutrons, and deuterons), and electromagnetic radiation such as gamma rays and X rays. From a biological point of view, the most important attribute of radiant energy is its ability to cause ionization—to form positively or negatively charged particles in the body tissues that it encounters, thereby altering and, in some cases, damaging the chemical composition of the cells. DNA is highly susceptible to ionizing radiation. Cells and tissues may therefore die because of damage to enzymes, because of the inability of the cell to survive with a defective complement of DNA, or because cells are unable to divide. The cell is most susceptible to irradiation during the process of division. The severity of radiation injury is dependent on the penetrability of the radiation, the area of the body exposed to radiation, and the duration of exposure, variables that determine the total amount of radiant energy absorbed.

When the radiation exposure is confined to a part of the body and is delivered in divided doses, a frequent practice in the treatment of cancer, its effect depends on the vulnerability of the cell types in the body to this form of energy. Some cells, such as those that divide actively, are particularly sensitive to radiation. In this category are the cells of the bone marrow, spleen, lymph nodes, sex glands, and lining of the stomach and intestines. In contrast, permanently nondividing cells of the body such as nerve and muscle cells are resistant to radiation. The goal of radiation therapy of tumours is to deliver a dosage to the tumours that is sufficient to destroy the cancer cells without too severely injuring the normal cells in the pathway of the radiation. Obviously, when an internal

cancer is treated, the skin, underlying fat, muscles, and nearby organs are unavoidably exposed to the radiation. The possibility of delivering effective doses of radiation to the unwanted cancer depends on the ability of the normal cells to withstand the radiation. However, as is the case in drug therapy, radiation treatment is a two-edged sword with both positive and negative aspects.

Finally, there are probable deleterious effects of radiation in producing congenital malformations, certain leukemias, and possibly some genetic disorders (see RADIATION: *Biologic effects of ionizing radiation*).

DISEASES OF IMMUNE ORIGIN

Types of immune disorders

The immune system protects against infectious disease, but it may also at times cause disease. Disorders of the immune system fall into two broad categories: (1) those that arise when some aspect of the host's immune mechanism fails to prevent infection (immune deficiencies) and (2) those that occur when the immune response is directed at an inappropriate antigen, such as a noninfectious agent in an allergic reaction, the body's own antigens in an autoimmune response, or the cells of a transplanted organ in graft rejection.

Immune deficiencies. The immune system may fail to function for many reasons. Many immunodeficiency disorders are caused by a genetic defect in some component of the system and thus usually manifest early in life. Some deficiencies, however, are acquired through the action of infectious agents such as viruses, through the action of immunosuppressive agents used to treat various medical conditions, and through the effects of certain disease processes such as cancer. Both inherited and acquired immune deficiencies suppress one or many aspects of the immune response, rendering the affected individual unable to resist infection unless treated by administration of immunoglobulins or by bone marrow transplant.

Inherited immune disorders undermine the immune response in a variety of ways: B lymphocytes may be unable to produce antibodies, phagocytes may be unable to digest microbes, or specific complement components may not be produced. Severe combined immunodeficiency (SCID), a condition that arises from several different genetic defects, disrupts the functioning of both the humoral and cell-mediated immune responses.

Acquired immune deficiency syndrome (AIDS) is caused by infection with the human immunodeficiency virus (HIV), which destroys a certain type of T lymphocyte, the helper T cell. An infected individual is susceptible to a variety of infectious organisms, including those called opportunistic pathogens, which may live benignly in the human body and cause disease only when the immune system is suppressed. Certain diseases such as Kaposi's sarcoma and *Pneumocystis carinii* pneumonia, which until recently were rarely encountered by clinicians, have become prevalent in the AIDS population and are often the cause of mortality.

Immune responses in the absence of infection. *Allergies.* The immune system may react to any foreign substance, and consequently it can respond to innocuous materials in the same way that it responds to infectious agents. If the foreign material poses no threat to the individual, an immune response is unnecessary, but it nevertheless may ensue. This misplaced response is called an allergy, or hypersensitivity, and the foreign material is referred to as an allergen. Common allergens include pollen, dust, bee venom, and various foods such as shellfish. What causes one person and not another to develop an allergy is not completely understood.

The allergic response

An allergic response occurs in the following manner. On first exposure to the allergen, the person becomes sensitized to it—that is, develops antibodies and specific T cells to the allergen. An allergic reaction does not usually accompany this initial event. When reexposure occurs, however, symptoms of the allergic response appear. These symptoms range from the mild response of sneezing and a runny nose to the sometimes life-threatening reaction of anaphylaxis, or anaphylactic shock, symptoms of which include vascular collapse and potentially fatal respiratory distress.

Allergic reactions exhibit different symptoms depending on which immune mechanisms are responsible. On the basis of this criterion, they can be categorized into four types, the first three of which involve antibodies and occur in a matter of minutes or hours. Type IV hypersensitivity, unlike the other reactions, does not involve antibodies but instead is mediated by T cells. In these reactions, also called delayed-type because they arise in a matter of days rather than minutes or hours, T cells either activate a local inflammatory reaction, which can cause extensive tissue damage, or they kill tissue cells directly. Chronic inflammation characteristic of many autoimmune disorders, such as chronic thyroiditis, results from this reaction. With the exception of the type I response, all responses are seen in both allergies and autoimmune disorders.

Autoimmune disorders. Immune responses can be mounted against proteins that belong to the host, giving rise to autoimmune diseases. Although the immune system naturally generates antibodies to its own cells, mechanisms exist to keep this activity in check. Two mechanisms that prevent the immune system from mounting an attack against the host's own tissues have been identified. The first involves the elimination of self-reactive lymphocytes during their development and maturation in the thymus, a lymphoid organ in the chest. Self-reactive lymphocytes present in these cell populations are destroyed when they encounter the self-antigen to which they react. Because this protective selection process is not highly efficient, some self-reactive lymphocytes survive, exit the thymus, and enter the blood and tissues. Outside the thymus a second line of defense against immune self-destruction is afforded in which self-reactive lymphocytes lose their ability to react to self-antigens when they are encountered in blood and tissues. This state is referred to as immunologic ignorance. Autoimmune diseases arise when this mechanism fails and self-reactive lymphocytes are activated by self-antigens in the host's own tissues, often with devastating effects. Systemic lupus erythematosus, thyroiditis, insulin-dependent diabetes mellitus, and rheumatoid arthritis are examples of this type of disorder.

Graft rejection. Transplantation of organs and cells from one individual to another has become an important medical treatment. As are other forms of therapy, it is accompanied by certain risks. Each individual's cells have a spectrum of genetically determined cell surface protein antigens, the major histocompatibility complex (MHC) antigens, or human leukocyte antigens as they are referred to in humans. MHC antigens determine a person's tissue type just as red blood cell antigens determine blood type. There are two classes of MHC antigens: class I molecules, encoded by three genes, and class II molecules, encoded by four possible sets of genes. Each of these genes has many alternative forms, and thus the probability of any two individuals—aside from siblings, especially identical twins—having the same form of each gene is extremely small. Even parents will have different tissue antigens from their children.

These differences in tissue antigens pose an obstacle to transplantation because it is highly likely that foreign donor tissue will introduce antigens in the recipient that will trigger an immune response leading to tissue death and rejection. However, by careful matching of the MHC type of donor and recipient, rejection can be diminished or avoided. Because perfect matching is possible only between identical twins or very close relatives, many transplants occur between less closely matched tissue types, and success is achieved with the administration of powerful immunosuppressive drugs.

DISEASES OF BIOTIC ORIGIN

Factors in infection. *Infectious agents.* Biotic agents include life-forms that range in size from the smallest virus, measuring approximately 20 nanometres (0.000 000 8 inch) in diameter, to tapeworms that achieve lengths of 10 metres (33 feet). These agents are commonly grouped as viruses, rickettsiae, bacteria, fungi, and parasites. The disease that these organisms cause is only incidental to their struggle for survival. Most of these agents do not require a human host for their life cycles. Many survive readily

in soil, water, or lower animal species and are harmless to humans. Other living organisms, which require the temperature range of endothermic (warm-blooded) animals, may flourish on the skin or in the secretions of fluids of the mouth or intestinal tract but do not invade tissue or cause disease under normal conditions. Thus there is a distinction to be made between infection and disease.

All animals are infected with biotic agents. Those agents that do not cause disease are termed nonpathogenic, or commensal. Those that invade and cause disease are termed pathogenic. *Streptococcus viridans* bacteria, for example, are found in the throats of more than 90 percent of healthy persons. In this area they are not considered pathogenic. The same organism cultured from the bloodstream, however, is highly pathogenic and usually indicates the presence of the disease subacute bacterial endocarditis (chronic bacterial invasion of the valves of the heart). In order for such nonpathogenic agents to achieve pathogenicity, they obviously must overcome the defenses of the host. Most biotic agents require a portal of entry through the intact skin or mucosal linings of the body. They must be present in sufficient number to escape the phagocytes. They must be capable of surviving the inflammatory and immune response. Ultimately, to induce disease, they must have sufficient virulence and invasiveness to cause significant tissue injury.

Invasiveness

Invasiveness and virulence. Invasiveness is the capability of penetrating and spreading throughout tissues. Remarkably, little is known of the factors that condition it. In a few instances enzymes produced by biotic agents have been identified that are capable of breaking down the integrity of the supporting tissues of the body, thereby preparing a pathway for the spread of the organism.

Only very few bacteria release such enzymes, however, and there are marked differences in invasiveness to be found among the various types of bacteria. The organism that causes diphtheria (*Corynebacterium diphtheriae*), for example, is capable of invading only the surface cells of the mouth and throat. The disease that results is caused by the production of a powerful exotoxin (a chemical substance produced by the organism and released into the surrounding tissues) that is absorbed into the bloodstream from the local infection within the throat. This exotoxin causes major damage in the heart and the nervous system. The diphtheria bacillus, therefore, is an example of a serious infection in which the organism has low invasiveness. In contrast, the bacterium that causes syphilis (*Treponema pallidum*) has a high degree of invasiveness. It is one of the rare biotic agents that are capable of penetrating intact skin and mucosal linings of the body.

The invasiveness of viruses undoubtedly is facilitated by their extremely small size, but, because of this size, the exact mechanism is difficult to study. In the case of fungi and parasites, the invasiveness is related to the life cycle of the organism. The formation of tiny spores by fungi and the smaller reproductive forms of the parasites provide vehicles by which infection may be drawn into the lungs or may pass through tiny defects in the skin or mucosal linings of the various openings and tracts of the body.

In general, virulence is the degree of toxicity or the injury-producing potential of a microorganism. The words virulence and pathogenicity are often used interchangeably. The virulence of bacteria usually relates to their capability of producing a powerful exotoxin or endotoxin. Invasiveness also adds to an organism's virulence by permitting it to spread.

Predisposition of the host. Up to this point, diseases caused by biotic agents have been considered in terms of the role of the invader. Equally important is the role of the host, the individual who contracts the disease. Any infectious disease is a test between the invader and the defender. Virulent organisms may be capable of inducing serious illness even in the most robust. The converse is perhaps more important. The weak host is prey to many forms of biotic infection, even those of low virulence and invasiveness. Some of the more important of the many factors that condition the level of resistance to biotic infection in the individual are age, with infancy and old age being times of maximum vulnerability; poor nutrition; genetic disorders and immunosuppressive agents, such as the human immunodeficiency virus, that compromise the immunologic system; and metabolic disorders such as diabetes that increase vulnerability to infectious agents.

Drugs as factors predisposing to disease

Therapeutic agents, paradoxically, also have become important factors in predisposing to disease of biotic origin and indeed in altering the incidence patterns of infectious disease. The drugs that are principally involved include those used to suppress the immune response, as well as the host of antimicrobial and antibiotic agents now employed in the treatment of infectious disease. Immunosuppressive drugs are used to block the immune response in patients about to receive an organ transplant and in the treatment of the autoimmune diseases, but such treatment renders the patient vulnerable to attack by biotic agents. Indeed, these immunologically compromised persons become susceptible to organisms of extremely low virulence.

Antimicrobial drugs also have drawbacks as well as benefits. A patient suffering from a streptococcal disease, for example, may appropriately be treated with penicillin. Certain strains of staphylococci, however, are resistant to penicillin. Although the streptococcal organisms, as well as other commensals, may be eradicated by the antibiotic, the resistant staphylococci begin to proliferate, possibly because the competition with other bacteria for nutrients and food supply has been removed. In this noncompetitive situation they may cause disease. More powerful antibiotics may destroy all bacteria, including staphylococci, but permit the unrestrained proliferation of fungi and other agents of low virulence that are nonetheless resistant to the antibiotic. Thus antibiotics have changed the entire frequency pattern of biotic disease. Organisms that have proved to be more resistant to antibiotics have become the more common causes of serious clinical infection. For this reason certain forms of drug-resistant bacteria that include *Escherichia coli, Aerobacter aerogenes, Pseudomonas aeruginosa,* and strains of *Proteus* as well as fungi have emerged as the important biotic causes of death.

Types of viral disease

Viral diseases. Of the many existing viruses, a few are of great importance as causes of human sickness. They are responsible for such diseases as smallpox, poliomyelitis, encephalitis, influenza, yellow fever, measles, and mumps and such minor disorders as warts and the common cold.

Viruses may survive for some time in the soil, in water, or in milk, but they cannot multiply unless they invade or parasitize living cells. Certain viruses proliferate within the host cells and accumulate in sufficient number to cause rupture and death of the cells. Others multiply within the cell body and compete with the host for nutrition or vital constituents of the cell's metabolism. Both types of viruses are said to be cytotoxic.

Viral agents, particularly those capable of producing tumours in humans and lower animals, flourish within cells and stimulate the cells to active growth. These viruses are referred to as oncogenic (tumour-producing). The number of oncogenic viruses that cause tumours in lower animals is large. In humans, several DNA viruses and one RNA virus have been implicated strongly in the induction of a variety of tumours (see CANCER).

Most viral infections occur in childhood. This age distribution has been explained on immunologic grounds. Viruses usually induce a firm and enduring immunity. On first exposure to a virus, children may or may not contract the disease, depending on their resistance, the size of the infective dose of virus, and many other variables. Those who contract the disease, as well as those who resist the infection, develop a permanent immunity to any further exposure. By either pathway, as children grow older they progressively gather protection against viral infections. Consequently, the incidence of these infections falls in adulthood and later life. The frequency of common colds is explained on the grounds that a host of different viral agents all induce similar respiratory infections, and, while a single attack confers immunity against the specific causative agent, it provides no protection against the rest.

Viral diseases are resistant to antibiotics and other antimicrobial agents. This point is made because of a distressing tendency among individuals to take penicillin or another antibiotic for a common cold.

Micro-organisms as cause

Rickettsial diseases. Human rickettsial diseases are caused by microorganisms that fall between viruses and bacteria in size. These minute agents are barely visible under the ordinary light microscope. Like viruses, they multiply only within the cells of susceptible hosts. They are found in nature in a variety of ticks and lice and, when transmitted to humans by the bite of one of these arthropods, usually cause acute febrile (fever-producing) illnesses, most of which are characterized by skin rashes. Rocky Mountain spotted fever, a systemic rickettsial infection, invades and kills the cells lining blood vessels and causes hemorrhage, inflammation, blood clots, and extensive tissue death; if untreated, it is fatal in about 20 to 30 percent of cases.

Bacterial diseases. The diseases produced by bacteria are the most common of infectious biotic diseases. They range from trivial skin infections to such devastating disorders as bubonic plague and tuberculosis. Various types of pneumonia; infections of the cerebrospinal fluid (meningitis), the liver, and the kidneys; and the sexually transmitted diseases syphilis and gonorrhea are all forms of bacterial infection.

All bacteria induce disease by one of three methods: (1) the production of an exotoxin, a harmful chemical substance that is secreted or excreted by the bacterium (as in food poisoning caused by *Clostridium botulinum*), (2) the elaboration of an endotoxin, a harmful chemical substance that is liberated only after disintegration of the microorganism (as in typhoid, caused by *Salmonella typhi*), or (3) the induction of sensitivity within the host to antigenic properties of the bacterial organism (as in tuberculosis, after sensitization to *Mycobacterium tuberculosis*).

Fungi and other parasites. Diseases caused by fungi and parasites are relatively uncommon in developed countries. Fungal infections, also known as mycotic infections, may affect the skin surfaces or the internal organs of the body. The superficial mycotic infections are generally not serious and include such well-known disorders as athlete's foot (tinea pedis), caused by the dermatophyte *Trichophyton*. Deep mycotic infections such as histoplasmosis and candidiasis are potentially life-threatening.

Other parasites that attack humans range in size from unicellular organisms such as *Entamoeba histolytica* to such multicellular forms as tapeworms and roundworms. Most parasitic infestations are encountered in the less-developed areas of the world where sanitation is not optimal. Indeed, parasitic infestations constitute major causes of death in regions of Central and South America, Africa, India, and Asia. (For additional information about diseases of biotic origin, see INFECTIOUS DISEASES.)

ABNORMAL GROWTH OF CELLS

Normal and abnormal cell growth. *Cell growth inhibition.* The growth of cells in the body is a closely controlled function, which, together with limited and regulated expression of various genes, gives rise to the many different tissues that constitute the whole organism. For the most part, control of cell growth persists throughout life except for episodic instances such as healing of an injured tissue. In this situation the growth of a localized group of cells is accelerated to reconstitute the tissue to its previous state of normal structure and function, following which tightly regulated growth resumes. Such areas of increased cell growth are referred to as hyperplasias; they consist of expanded numbers of normal-appearing cells and, depending on the duration of growth, can result in an enlargement of tissues and organs. In general, hyperplasias arise to meet special needs of the body and subside once these needs are met. Hyperplasias are the result of the sustained impact over time of stimulatory influences together with a loss of growth-inhibitory factors that are normally found within or around cells. As long as the loss of inhibition of cell growth is temporary, the capacity for enhanced cell proliferation when necessary has obvious advantages. However, if cells permanently lose their ability to respond to growth-inhibitory factors, their growth becomes irrepressible, and cancer may result.

Hyperplasia

Neoplasms: malignant and benign tumours. Diseases arising from uncontrolled cell growth and behaviour collectively constitute the second most common cause of human death (the most common cause being heart disease). Cancers, the most important form of abnormal growth and behaviour, were responsible for approximately 538,000 deaths, or almost one-fourth of all deaths, in the United States in 1994. The significance of this incidence is placed in proper perspective by a consideration of the following facts. While cancer arises at all stages of life, its incidence (number of cases) increases with age, reaching a peak between 55 and 74 years. This fact, together with the increasing longevity of the general population and improved diagnostic modalities that enable clinicians to detect cancers with greater frequency, tempers the notion that the incidence of cancer is increasing.

In addition to cancers—malignant tumours that may eventually kill the host—there are benign tumours that rarely produce serious disease. The two types of tumours are collectively referred to as neoplasms (new growths), and their study is known as oncology. Tumours are referred to as malignant or benign based on the structural and functional properties of their component cells and their biological behaviour. The cells and tissues of malignant tumours differ from the tissues from which they arise. They exhibit more rapid growth and altered structure and function, including stimulation of new blood vessel growth (angiogenesis) and a capacity to invade adjacent normal tissues, enter the blood vascular system, and spread (metastasize) to distant sites. The properties of malignant tumour cells serve to enhance and support their proliferation and extension throughout the body tissues and organs, eventually leading to death of the host. In contrast, the cells and tissues of benign tumours tend to grow more slowly and in general closely resemble their normal tissues of origin. When the structure and function of benign tumour cells are morphologically and functionally indistinguishable from those of normal cells, their growth as a tumour mass is the sole feature indicative of their neoplastic nature. It is hoped that a greater understanding of malignant cell growth and behaviour will lead to the development of novel cancer therapies based on tumour cell biology that will complement or replace the current treatments of surgical extirpation (complete excision), chemotherapy, and radiation.

Growth characteristics of tumours

Characteristics of cancer. *Epidemiology.* Epidemiological studies of the worldwide incidence of cancers have identified striking differences among countries and population groups. For example, the incidence of and death rates for skin cancer are much higher in Australia and New Zealand than in the Scandinavian countries—presumably because of the marked differences between these two regions in total annual hours of exposure to sunlight. The importance of environmental influences is highlighted by comparing the incidence of and death rates for cancers among populations in different geographic regions. For example, prostate and colon cancer rates in Japanese persons living in Japan differ from the rates in Japanese persons who have emigrated to the United States, the rates of their offspring born in California, and the rates of long-term white residents of that state. These rates are much lower among Japanese living in Japan than they are in white Californians. However, the rates for each type of tumour among first-generation Japanese immigrants are intermediate between the rates in Japan and those in California, suggesting that environmental and cultural factors may play a more important role than genetic ones.

The role of genetics. The irreversibility of the structural and behavioral changes of cancer cells has long been recognized and has favoured the postulate that they are probably due to permanent genetic alterations. This postulate remained speculative until the discovery in 1979 that oncogenes (cancer-causing genes) are derived from proto-oncogenes (normal growth-regulatory cellular genes). When proto-oncogenes become mutated or deregulated, they are converted to oncogenes, which are capable of causing the malignant transformation of cells, including those of humans. Cellular proto-oncogenes code for proteins involved in cell regulation, such as growth factors, their receptors, and transmembrane signal transducers. Thus, changes in the structure of proto-oncogenes and

their conversion to oncogenes results in the synthesis of abnormal proteins that are incapable of carrying out their usual growth-regulatory functions. In identifying the genes involved in the development of cancer, researchers discovered a group of cellular genes—tumour-suppressor, or suppressor, genes—whose protein products normally negatively regulate cell growth by suppressing cell proliferation, thus counterbalancing the growth-stimulatory effects of proteins synthesized by proto-oncogenes. Genetic analyses of various animal and human cancers have demonstrated that, in the majority, alterations of oncogenes and suppressor genes were often simultaneously present. These analyses suggest that multiple genetic alterations involving growth-stimulatory and growth-inhibitory genes are required for the induction of malignancy. Such discoveries have ushered in a new era in cancer biology and may well lead to the eventual control, cure, and prevention of malignant diseases.

Heredity and environment. The many causes of cancer include intrinsic factors, such as heredity, and extrinsic factors, such as environment and lifestyle. Hereditary causes of cancer are less common and are due to the inheritance of a single mutant gene that greatly increases the risk of developing a malignant tumour. Such cancers include (1) a childhood tumour of the eye, retinoblastoma, and a bone tumour, osteosarcoma, both of which involve the loss of a tumour suppressor gene, and (2) familial adenomatous polyposis, in which all patients develop colon cancer by age 50. The most common types of cancer that occur sporadically, such as cancers of the breast, ovary, colon, and pancreas, also have been documented to occur in familial forms. The children in such families appear to have a two- to threefold increased risk of developing a particular tumour, but the transmission pattern is unclear. A still rarer hereditary cause of cancer is an inherited deficiency in the ability to repair DNA. Patients with this defect (known as xeroderma pigmentosum) are particularly sensitive to sunlight and develop skin cancer during early adolescence because of unrepaired mutations induced by ultraviolet (UV) light.

Familial types of cancer

Although the environment contains many agents that can cause cancer in humans, the extent to which they contribute to the human disease is often difficult to assess. For example, the link between tobacco smoking and lung cancer is clear; however, little is known about the cause of cancer of the prostate, the most common form of cancer in males, despite the fact that many factors—including age, race, male hormone, increased consumption of dietary fat, and a genetic basis—have been implicated.

Three categories of carcinogens (chemical or physical agents that mutate DNA) that induce cancer in experimental animals and humans have been identified in the environment: (1) chemicals, (2) radiant energy, and (3) oncogenic viruses.

Carcinogenic agents. *Chemicals.* Chemicals capable of causing cancer arise from a variety of sources. These include certain synthetic chemicals used in industry, some natural compounds formed during the curing and burning of tobacco, compounds formed during the cooking of meat, and chemicals present in certain plants and molds. Two categories have been identified, those capable of causing DNA damage and mutations directly (genotoxic, or direct-acting, carcinogens) and those that require prior metabolic activation by cells of the host to be converted to mutagens (epigenic, or indirect-acting, carcinogens). In the industrial countries much progress has been made in significantly decreasing and preventing exposure to chemical carcinogens in the workplace. However, exposure to carcinogens as a consequence of cultural practices, such as tobacco smoking and the cooking and consumption of meats, is difficult if not impossible to control or eradicate.

Radiant energy. Sustained exposure to two forms of radiant energy—namely, UV light and ionizing radiation—is carcinogenic for humans. Repeated and sustained exposure to UV rays emanating from the Sun causes mutations of DNA that ultimately are capable of inducing three different types of skin cancer. As one would expect, the incidence of UV-induced skin cancer is high among farmers, sailors, and sunbathing enthusiasts. The degree of risk depends on the extent of exposure and the amount of melanin pigment in the skin, which absorbs UV rays. Dark-skinned individuals are protected by the high content of melanin in their skin; in contrast, fair-skinned persons and albinos have very little or no protective melanin pigment in their skin.

UV light and ionizing radiation

The carcinogenic effects of ionizing radiation first became apparent from the results of inappropriate exposure of early uranium ore miners and of physicians who first used X-ray machines for diagnostic purposes and were unaware of the health hazards. The devastating complications that resulted are rare today because of stricter indications for the use of radiation therapy, careful focusing of radiation beams, and effective shielding of adjacent normal tissues. However, the risks of exposure to ionizing radiation have been reemphasized from time to time by the appearance of neoplastic disease following radiation therapy and following the release of enormous amounts of radiation into the environment, as occurred from atomic bombing of Hiroshima and Nagasaki in Japan and the accident at the Chernobyl nuclear power station in Ukraine.

Reactive forms of carcinogenic chemicals and, in the case of ionizing radiation, reactive forms of oxygen damage DNA directly. If repair of damaged DNA is slow, error-prone, or not accomplished at all and cell replication occurs, the damage is amplified and becomes a permanent (fixed) mutation.

Viruses. In recent years certain DNA viruses have been strongly implicated as causal agents for a variety of cancers in humans. These include human papillomavirus (HPV) as a cause of genital cancers in both sexes worldwide, the Epstein-Barr virus (EBV) for childhood lymphoma in Africa and cancer of the nose and throat in Asia and Africa, and the hepatitis viruses B and C that cause liver cancer worldwide with the highest incidence in Asia and Africa. However, at present only one type of human cancer, the rare adult T-cell leukemia, has been solidly linked to infection with an RNA virus, the human T-cell leukemia virus (HTLV-1). While much experimental and clinical evidence supports the carcinogenic role of the above-mentioned viruses in humans, additional research suggests that other factors also may be required. Thus far, oncogenic viruses have not been shown to induce DNA mutations directly in human cells; rather, their contribution seems to lie in promoting and hastening the process of mutation. (For greater detail on how viruses contribute to the induction of cancer, see the articles CANCER and VIRUSES.)

DISEASES OF METABOLIC-ENDOCRINE ORIGIN

The term metabolism encompasses all the chemical reactions vital to the growth and maintenance of the body. Defects in metabolism are found in almost every disease condition. Most are secondary; *i.e.*, they result from some other basic disorder (infection, kidney disease, or heart disease, for example). In a few primary metabolic disorders, small genetic mutations lead to structural alterations of specific proteins that disrupt protein function and are responsible for the disease state. At this point, another group of primary metabolic disorders—those associated with hormonal defects—will be touched on.

Hormones are large organic molecules secreted in small amounts by specific cells in the various endocrine (ductless) glands. These secretions are carried by the blood to distant sites (target organs), where they bind to specific receptors on target cells and act to regulate specific chemical reactions.

Cause of endocrine disease

All endocrine disease stems from either an overproduction (hyperfunction) or underproduction (hypofunction) of some hormone-secreting endocrine gland. There are relatively few causes of hormone overproduction. In general, overproduction results from hyperplasia, an increase in the number of cells (in this case, hormone-secreting cells) in a specific endocrine gland. It can also be caused by neoplasia, the growth of a tumour in an endocrine gland. Although most endocrine tumours are benign, the resulting hypersecretion of hormone can have far-reaching effects. For example, the pituitary gland, tucked into the base of the skull, produces many hormones that have far-ranging

effects, mostly controlling the function of the other endocrine glands, such as the thyroid, adrenals, ovaries, and testes. Acromegaly, characterized by the enlargement of many skeletal parts, is a rare endocrine disease caused by excess secretion of pituitary growth hormone in the adult.

Underproduction of hormone is most often the result of destruction of hormone-secreting cells. This destruction may be caused by infection, infarction (tissue death due to loss of blood supply), or obliteration of endocrine glands by cancer. Underproduction of hormone also may result from failure of the gland to undergo normal fetal development, or it may be a feature of an autoimmune disease (as in juvenile diabetes mellitus).

Treatment of endocrine disease involves either hormone supplementation, in the case of hypofunction, or, in cases of hyperfunction, destruction of endocrine gland tissue by surgery or radiation (see ENDOCRINE SYSTEMS).

DISEASES OF NUTRITION

Diseases of nutrition include the effects of undernutrition, prevalent in less-developed areas but present even in affluent societies, and the effects of nutritional excess.

Diseases of nutritional excess. Obesity, perhaps the most important nutritional disease in the United States and Europe, results usually from excessive caloric intake, although emotional, genetic, and endocrine factors may be present.

Obesity predisposes one toward several serious disorders, including a state of chronic oxygen deficiency called the hypoventilation syndrome; high blood pressure; and atherosclerosis, a degenerative condition of the blood vessels that is discussed further below.

Excessive intake of certain vitamins, especially vitamins A and D, can also produce disease. Vitamins A and D are both fat-soluble and tend to accumulate to toxic levels in the bodily tissues when taken in excessive quantities. Vitamin C and the B vitamins, soluble in water, are more easily metabolized or excreted and, therefore, rarely accumulate to toxic levels.

Types of nutritional deficiency

Diseases of nutritional deficiency. Nutritional deficiencies may take the form of inadequacies of (1) total caloric intake, (2) protein intake, or (3) certain essential nutrients such as the vitamins and, more rarely, specific amino acids (components of proteins) and fatty acids.

Protein-calorie malnutrition remains prevalent in certain areas. It has been estimated that about two-thirds of the world's population has less than enough food to eat. Not only is the quantity inadequate but the quality of the food is nutritionally deficient and usually lacks protein. In deprived areas malnutrition has its greatest impact on the young. Deaths from protein-calorie malnutrition result from the failure of the child to thrive, with progressive weight loss and weakness, which in turn can lead to infection and disease, usually some form of gastrointestinal bacterial or parasitic disorder. In other circumstances adequate calories may be available, but a deficiency of protein induces a disorder known as kwashiorkor.

Vitamin deficiencies, the most important forms of selective malnutrition, may arise in a variety of ways, the most common and the most important being an improper, inadequate diet. When the total caloric intake is inadequate, vitamin deficiencies may also occur, but in these circumstances the more profound lack of calories and proteins masks the lack of vitamins.

Secondary vitamin deficiencies

Vitamin deficiencies may also be encountered despite a diet that is apparently adequate nutritionally. One source of such a deficiency, called secondary, is interference with absorption of the vitamin. Pernicious anemia is a classic example of this phenomenon. This disorder results from an autoimmune response to intrinsic factor, a substance normally found in the stomach lining with which vitamin B_{12} must form a complex to be absorbed. (Vitamin B_{12} is necessary for red cells to form properly.) The basis of pernicious anemia, then, is a lack of absorption of vitamin B_{12}. The absence of certain digestive enzymes, as is found in pancreatic disease, can lead to the inability to digest and absorb fats and the fat-soluble vitamins (A, D, E, and K). Impaired uptake of vitamins may be encountered in gastrointestinal diseases. Some of these diseases reduce the absorptive function of the bowel. Similarly, diseases associated with severe, prolonged vomiting may interfere with adequate absorption.

Avitaminosis (vitamin lack) may be encountered when there are increased losses of vitamins such as occur with chronic severe diarrhea or excessive sweating or when there are increased requirements for vitamins during periods of rapid growth, especially during childhood and pregnancy. Fever and the endocrine disorder hyperthyroidism are two additional examples of conditions that require higher than the usual levels of vitamin intake. Unless the diet is adjusted to the increased requirements, deficiencies may develop. Lastly, artificial manipulation of the body and its natural metabolic pathways, as by certain surgical procedures or the administration of various drugs, can lead to avitaminoses. (Diseases involving deficiencies of particular vitamins are discussed in NUTRITION: *Deficiency diseases: Vitamins*.)

DISEASES OF NEUROPSYCHIATRIC ORIGIN

Diseases of neuropsychiatric origin afflict large segments of the population. For example, a total of about 2.8 million persons in the United States suffer from three major psychiatric diseases—schizophrenia, major depression, and mania—and three major neurological disorders—Alzheimer's disease, Huntington's chorea, and Parkinson's disease. These six conditions will be briefly reviewed here. More in-depth coverage is found in the articles MENTAL DISORDERS AND THEIR TREATMENT and NERVES AND NERVOUS SYSTEMS.

Communication within the nervous system

The key function of the nervous system is to collect information about the body and its external environment, process the information, and coordinate the body's responses to that information. This complex function depends on each nerve cell (neuron) receiving signals from other neurons and transmitting this input to still other neurons. This critical input and output of communication (signaling) between neurons is mediated by chemical transmitter molecules (neurotransmitters). Neurotransmitters are synthesized by nerve cells and released from one cell to another across a narrow gap between the two neurons known as the synapse. Eight different major neurotransmitters and a large number of neuropeptide molecules (which serve to modulate the effects of neurotransmitters) have been identified. Different types of nerve cells respond to different neurotransmitters and neuropeptides. Chemical signaling between nerve cells is rapid and precise and can occur over long distances. The precision is due to receptor molecules, which are activated following their recognition and binding of specific neurotransmitters. In some types of nerves the synapses do not possess receptors, in which case interneuronal communication is achieved by electrical transmission. In many neuropsychiatric diseases alterations in the levels of transmitter substances appear to play a major role in pathogenesis.

Psychiatric diseases. Mental illnesses affect the very fabric of human nature, robbing it of its various facets of personality, purposeful behaviour, abstract thinking, creativity, emotion, and mood. Those suffering from mental disorders exhibit a spectrum of symptoms depending on the severity of their disease. These diseases include obsessive-compulsive personality disorder, dementia, schizophrenia, major depression, and manic disorders.

Schizophrenia

Schizophrenia in its severe form is a catastrophic mental illness that begins in adolescence or early adult life. It is relatively common, occurring in about 1 percent of the general population worldwide. Because the incidence of schizophrenia among parents, children, and siblings of patients with the disease is increased to 15 percent, it is believed that heredity plays an important role in the genesis of the disease. However, other studies suggest that nongenetic factors are also influential. The biochemical basis of the disease may be an excess of the neurotransmitter substance dopamine, as high levels of dopamine and its metabolites, as well as increased dopamine receptors, are found in the brains of persons with schizophrenia. Further evidence for this hypothesis is that the drugs most effective in treating the disease are those that have a high capacity to block dopamine receptors.

Pathological disturbances of mood, ranging from severe depression to manic behaviour, are common forms of mental illnesses. Severe depression is characterized by despondency, diminished interest in most or all activities, weight fluctuation not due to dieting, disruption in sleep patterns, psychomotor agitation or retardation, feelings of worthlessness, excessive quiet, and recurrent thoughts of death or suicide. Manic behaviour involves a period in which an expansive, elevated, or irritable mood persists abnormally. During this episode symptoms such as increased talkativeness, distractibility, decreased need for sleep, inflated self-esteem, and excessive involvement in pleasurable yet risky activities may be present. Major depression is associated with decreased brain levels of the neurotransmitters norepinephrine and serotonin, and the most effective therapy consists of drugs that inhibit the breakdown of these compounds. The neurochemical alterations in mania are less clearly understood, but it is well established that drugs effective in the treatment of mania are those that antagonize dopamine and serotonin. The mechanism responsible for the therapeutic efficacy of lithium for the treatment of mania is not yet clear. Although mood disorders have a familial background, the evidence for a genetic component is not convincing.

Neurological diseases. The three neurological diseases considered in this section—Alzheimer's disease, Huntington's chorea, and Parkinson's disease—are age-related, and to varying degrees they manifest as deterioration of mental function that involves the loss of memory and of acquired intellectual skills. This deterioration is referred to as dementia. Because dementia can result from many causes, other features of each disease must be present before a definitive diagnosis can be made.

Alzheimer's disease. Alzheimer's disease is the most common form of dementia, being responsible for about two-thirds of the cases of dementia in patients over 60 years of age. Women are affected twice as often as men. More rarely there are familial forms of the disease that have an early onset affecting individuals in the fourth and fifth decades of life. Alzheimer's disease is insidious in onset. Early manifestations include memory loss, temporary confusion, restlessness, poor judgment, and lethargy. A failure to retain new information and a deterioration of social relationships often ensue. In some patients paranoia and delusions are the first symptoms of the disease. Whatever the onset, the last stages are characterized by intellectual vacuity and loss of control over all body functions.

The brains of patients with Alzheimer's disease are characterized by the loss of neurons, which, as the disease progresses, becomes severe and leads to decreased brain size and weight. Because nerve cells synthesize the neurotransmitters necessary for interneuronal communication, it is not surprising that Alzheimer's disease is associated with diminished levels of neurotransmitters, including acetylcholine, norepinephrine, and serotonin, as well as modulatory neuropeptide molecules that transmit signals between nerve cells. Two other characteristic tissue lesions found in the cerebral cortex of patients with Alzheimer's disease are neuritic plaques and neurofibrillary tangles. Neuritic plaques are deposits of neuron fragments surrounding a core of amyloid β-protein. Neurofibrillary tangles are twisted fibres of the protein tau found within neurons.

A variety of genetic factors have been identified in the different forms of Alzheimer's disease. The rare cases of the early familial forms of the disease are linked to three different genetic defects found on three different chromosomes—chromosomes 1, 14, and 21. Another gene on chromosome 19 is believed to play a part in the more common late-onset cases. The gene on chromosome 21 was the first to be identified. (This finding is significant because an abnormality in chromosome 21—an extra copy—is found in patients with Down syndrome, virtually all of whom develop Alzheimer's disease if they live to age 35.) The defective gene on chromosome 21 normally codes for amyloid precursor protein. A defect in this gene is thought to result in abnormal cleavage of the protein that increases the production and deposition of amyloid β-protein. This gene, however, is linked to only 2 to 3 percent of all early familial cases of the disease. The majority of patients with early-onset disease—70 to 80 percent—have the genetic mutation on chromosome 14, and another group of patients have a defective gene on chromosome 1. The gene on chromosome 19 codes for apolipoprotein E, a protein involved in cholesterol transport and metabolism. Three forms, or alleles, of the gene exist. The presence of one form—ApoE4—in an individual's genome seems to increase the deposition of amyloid β-protein in the brain and may also increase the number of neurofibrillary tangles.

Huntington's chorea. Huntington's chorea occurs at the rate of about 5 per 100,000 individuals. It affects both sexes equally and usually becomes manifest in the fourth decade of life. The disorder is characterized by uncontrolled movements (chorea), dementia, and death within 20 years after onset. The symptoms worsen until the patient becomes totally incapacitated and bedridden. Huntington's chorea is a hereditary disease passed on as an autosomal dominant trait (see above *Diseases of genetic origin*). Because of its highly regular familial inheritance, the disease is often traceable to the original carriers who introduced the defective gene. For example, British immigrants to colonial America in the 17th century are believed to be responsible for almost all cases of Huntington's chorea in the eastern United States, and an English sailor is thought to have introduced the defective gene into Venezuela almost 200 years ago. The recent localization of the Huntington's chorea gene to chromosome 4 and its cloning will allow identification of the gene product, insight into the mechanism responsible for the disease, and perhaps effective treatment. It will also permit the disease to be diagnosed in fetuses as well as in children before the onset of symptoms.

Parkinson's disease. Parkinson's disease is a motor disorder characterized by the onset of a "pill rolling" rhythmic tremor, muscle rigidity, difficulty and slowness in movement, and stooped posture. As the disease progresses, the face of the patient becomes expressionless, the rate of swallowing is reduced, leading to drooling, and depression and dementia increase. The prevalence of Parkinson's disease is estimated to be about 187 per 100,000 persons in the general population, with about 20 new cases per 100,000 appearing each year. Men are slightly more affected than women, and there are no apparent racial differences. The disease appears typically in the sixth and seventh decades, although occasionally it can begin as early as the third decade. While the majority of cases of Parkinson's disease are of unknown cause, the disease was linked to a complication of encephalitis that developed following the worldwide outbreak of influenza during World War I and, more recently, to an episode of use by intravenous drug abusers of a synthetic drug similar to heroin. A marked decrease in the level of dopamine, a major neurotransmitter, has been noted in the brains of patients with Parkinson's disease, and this change has been attributed to the loss of so-called dopaminergic neurons that normally synthesize and use dopamine to communicate with other neurons in parts of the brain that regulate motor function. This information has opened a new approach to the treatment of the disease—namely, administration of the metabolic precursor to dopamine (L-dopa) that can be converted by the body to dopamine. Although initially beneficial in causing a significant remission of symptoms, L-dopa frequently is effective for only 5 to 10 years, and serious side effects accompany treatment. Cotreatment with an inhibitor of the enzyme that breaks down L-dopa and thus allows the substance to remain in the brain longer has yielded an effective therapy, which allows many patients to live reasonably normal lives. Treatment of the disease with fetal tissue transplants, while raising ethical and legal issues, also has shown promise in alleviating symptoms. Nevertheless, although treatment may slow the progress of the disease, it does not alter its course. This suggests that factors other than variation in neurotransmitter levels are responsible for the disease.

Treatment of Parkinson's disease

DISEASES OF SENESCENCE

The process of aging begins at the time of conception. Throughout life the body undergoes a series of changes

that can be considered as manifestations of aging. During the first half of life these changes are generally referred to as maturation, during the last half of life as progressive senescence. Visual acuity, sensitivity of hearing, and muscular vigour begin to deteriorate after the third decade of life. These changes, although they may begin at different ages and progress at differing rates, are universal among all individuals and must therefore be considered as the normal aging process. A critical question remains unanswered concerning the cause of the intrinsic retrogressive changes in cell and organ structure and function that occur throughout the aging process. Are these changes genetically determined, or are they a result of accumulated sublethal injuries that the cell sustains from exposure to noxious environmental factors over time? Or perhaps both elements act in concert to effect the changes that occur as life progresses.

It is extremely difficult to draw a sharp line between the deleterious effects of normal aging and the deleterious effects of the diseases of aging. The diseases most commonly manifested in the elderly are disorders of the heart, blood vessels, and joints. The heart disease of the elderly is related to the generalized vascular disease known as arteriosclerosis, which frequently attacks the major coronary arteries of the heart. Arteriosclerosis and arthritis will therefore be briefly touched upon here. More extended discussions may be found in CIRCULATION AND CIRCULATORY SYSTEMS: *Cardiovascular system diseases and disorders* and in SUPPORTIVE AND CONNECTIVE TISSUES: *Joint diseases and injuries*. These problems and other aspects of aging are also considered in GROWTH AND DEVELOPMENT: *Human aging*.

Arteriosclerosis is not a specific disease. The term is applied to all diseases that cause hardening of the arteries. Several minor processes can induce hardening of the arteries, but the overwhelming preponderance of cases of arteriosclerosis are caused by atherosclerosis. This disorder, which eventually affects all individuals to varying degrees, begins relatively early in life in most persons. There are great variations, however, in the severity of this disease among individuals and among racial, national, and ethnic populations. These differences depend on the presence or absence of risk factors such as diet, hypertension, tobacco smoking, diabetes, obesity, family history, and stress.

Atherosclerosis

Atherosclerosis is characterized by the deposition of fats (cholesterol and other complex lipids) in the linings (intima) of the arteries. It is accompanied by cell injury, cell death, and scarring and sometimes produces total obstruction of an artery. Atherosclerosis has a predilection for the aorta, the major artery of the body, and the arteries of the heart, brain, and legs. Atherosclerosis of the arteries of the heart (the coronaries) causes myocardial infarction, otherwise known as heart attack.

When atherosclerosis narrows but does not totally block the coronary arteries, the heart also is injured by lack of adequate blood supply and nutrition and becomes progressively smaller and weaker; even though this disease is not as life-threatening as a heart attack, it nonetheless frequently causes heart failure, an inability of the heart to deliver an adequate supply of blood to the tissues. Atherosclerosis of the arteries of the brain is the usual cause of stroke. When the arteries to the legs become affected in this way, gangrene may develop.

Arthritis, probably the second most common and distressing disease among the elderly, is a disease of the joints. It causes considerable pain, discomfort, and lack of mobility and so makes life burdensome. Moreover, arthritic individuals are more subject to other illnesses. Degenerative arthritis (osteoarthritis) is common to all elderly people to a lesser or greater degree. Osteoarthritis usually begins in the fourth decade of life and slowly progresses with increasing age. Coinciding with the characteristic degeneration of the joints are changes involving the bone itself. The bone of elderly persons is known to be less dense and more brittle; it tends, therefore, to fracture more easily. It also heals with greater difficulty.

There are many subtle changes that occur with the normal aging process. These may include degenerative changes in the brain, leading to impaired mental ability and even senility. As this damage is usually accompanied by atherosclerosis of the arteries of the brain, it is difficult to know how much of the change is the result of impaired blood flow and how much is related to normal aging. Finally, but of no less significance, is the general decline in the body's ability to defend itself against disease. Thus elderly persons are more susceptible to infections, trauma, and a number of other bodily defects. Simple, uncomplicated pneumonia, which might be easily tolerated by the young, healthy adult, may be fatal for an elderly, weakened person.

Classifications of diseases

Value of disease classification

Classifications of diseases become extremely important in the compilation of statistics on causes of illness (morbidity) and causes of death (mortality). It is obviously important to know what kinds of illness and disease are prevalent in an area and how these prevalence rates vary with time. Classifying diseases made it apparent, for example, that the frequency of lung cancer was entering a period of alarming increase in the mid-20th century. Once a rare form of cancer, it had become the single most important form of cancer in males. With this knowledge a search was instituted for possible causes of this increased prevalence. It was concluded that the occurrence of lung cancer was closely associated with cigarette smoking. Classification of disease had helped to ferret out an important, frequently causal, relationship.

The most widely used classifications of disease are (1) topographic, by bodily region or system, (2) anatomic, by organ or tissue, (3) physiological, by function or effect, (4) pathological, by the nature of the disease process, (5) etiologic (causal), (6) juristic, by speed of advent of death, (7) epidemiological, and (8) statistical. Any single disease may fall within several of these classifications.

In the topographic classification, diseases are subdivided into such categories as gastrointestinal disease, vascular disease, abdominal disease, and chest disease. Various specializations within medicine follow such topographic or systemic divisions, so that there are physicians who are essentially vascular surgeons, for example, or clinicians who are specialized in gastrointestinal disease. Similarly, some physicians have become specialized in chest disease and concentrate principally on diseases of the heart and lungs.

In the anatomic classification, disease is categorized by the specific organ or tissue affected; hence, heart disease, liver disease, and lung disease. Medical specialties such as cardiology are restricted to diseases of a single organ, in this case the heart. Such a classification has its greatest use in identifying the various kinds of disease that affect a particular organ. The heart is a good example to consider. By the segregation of cardiac disease it has been made apparent that heart disease is now the most important cause of death in the United States and in most other industrialized nations. Moreover, it has become apparent that disease caused by atherosclerosis of the coronary arteries is by far the most important form of heart disease. In making a diagnosis of cardiac disease in an elderly patient, the cardiologist must first determine whether this disease of the coronary arteries is responsible for the heart's failure to function normally.

Physiological classification of disease

The physiological classification of disease is based on the underlying functional derangement produced by a specific disorder. Included in this classification are such designations as respiratory and metabolic disease. Respiratory diseases are those that interfere with the intake and expulsion of air and the exchange of oxygen for carbon dioxide in the lungs. Metabolic diseases are those in which disturbances of the body's chemical processes are a basic feature. Diabetes and gout are examples.

The pathological classification of disease considers the nature of the disease process. Neoplastic and inflammatory disease are examples. Neoplastic disease includes the whole range of tumours, particularly cancers, and their effect on human beings.

The etiologic classification of disease is based on the cause, when known. This classification is particularly important and useful in the consideration of biotic disease.

On this basis disease might be classified as staphylococcal or rickettsial or fungal, to cite only a few instances. It is important to know, for example, what kinds of disease staphylococci produce in human beings. It is well known that they cause skin infections and pneumonia, but it is also important to note how often they cause meningitis, abscesses in the liver, and kidney infections. The sexually transmitted diseases syphilis and gonorrhea are further examples of diseases classified by etiology.

The juristic basis of the classification of disease is concerned with the legal circumstances in which death occurs. It is principally involved with sudden death, the cause of which is not clearly evident. Thus, on a juristic basis some deaths and diseases are classified as medical-legal and fall within the jurisdiction of coroners and medical examiners. A person living alone is found dead in bed—dead of natural causes or killed? Had the person who dropped dead on the street been given some poison that took a short time to act? Much less dramatic, but perhaps more common, are disease and death caused by exposure of the individual to some unrecognized danger to health in working or living conditions. Could the illness or disease be attributable to fumes or dusts in a factory? These are examples of the many types of disease and death that fall properly in this classification.

Epidemiological classification

The epidemiological classification of disease deals with the incidence, distribution, and control of disorders in a population. To use the example of typhoid, a disease spread through contaminated food and water, it first becomes important to establish that the disease observed is truly caused by *Salmonella typhi*, the typhoid organism. Once the diagnosis is established, it is obviously important to know the number of cases, whether the cases were scattered over the course of a year or occurred within a short period, and what the geographic distribution is. It is critically important that the precise address and activities of the patients be established. Two widely separated locations within the same city might be found to have clusters of cases of typhoid all arising virtually simultaneously. It might be found that each of these clusters revolved about a family unit including cousins, grandparents, aunts and uncles, and friends, suggesting that in some way personal relationships might be important. Further investigation might disclose that all the infected persons had dined at one time or at short intervals in a specific home. It might further be found that the person who had prepared the meal had recently visited some rural area and had suffered a mild attack of the disease and was now spreading it to family and friends by unknowing contamination of food. This hypothetical case suggests the importance of the etiologic, as well as the epidemiological, classification of disease.

Epidemiology is one of the important sciences in the study of nutritional and biotic diseases around the world. The United Nations supports, in part, the World Health Organization, whose chief function is the worldwide investigation of the distribution of disease. In the course of this investigation, many observations have been made that help to explain the cause and provide approaches to the control of many diseases.

Statistical classification

The statistical basis of classification of disease employs analysis of the incidence (the numbers of new cases of a specific disease that occur during a certain period) and the prevalence rate (number of cases of a disease in existence at a certain time) of diseases. If, for example, a disease has an incidence rate of 100 cases per year in a given locale and, on the average, the affected persons live three years with the disease, it is obvious that the prevalence of the disease is 300. Statistical classification is an additional important tool in the study of possible causes of disease. These studies, as well as epidemiological, nutritional, and pathological analyses, have made it clear, for example, that diet is an important consideration in the possible causation of atherosclerosis. The statistical analyses drew attention to the role of high levels of fats and carbohydrates in the diet in the possible causation of atherosclerosis. The analyses further drew attention to the fact that certain populations that do not eat large quantities of animal fats and subsist largely on vegetable oils and fish have a much lower incidence of atherosclerosis. Thus, statistical surveys are of great importance in the study of human disease.

(S.L.R./J.H.Ro./D.G.Sc.)

DISEASES OF ANIMALS

Concern with diseases that afflict animals dates from the earliest human contacts with animals and is reflected in early views of religion and magic. Diseases of animals remain a concern principally because of the economic losses they cause and the possible transmission of the causative agents to humans. The branch of medicine called veterinary medicine deals with the study, prevention, and treatment of diseases not only in domesticated animals but also in wild animals and in animals used in scientific research. The prevention, control, and eradication of diseases of economically important animals are agricultural concerns. Programs for the control of diseases communicable from animals to man, called zoonoses, especially those in pets and in wildlife, are closely related to human health. Further, the diseases of animals are of increasing importance, for a primary public-health problem throughout the world is animal-protein deficiency in the diet of humans. Indeed, both the United Nations Food and Agricultural Organization (FAO) and the World Health Organization (WHO) have been attempting to solve the problem of protein deficits in a world whose human population is rapidly expanding.

General considerations

HISTORICAL BACKGROUND

Parallel development with human medicine

Historical evidence, like that from currently developing nations, indicates that veterinary medicine originally developed in response to the needs of pastoral and agricultural man along with human medicine. It seems likely that a veterinary profession existed throughout a large area of Africa and Asia from at least 2000 BC. Ancient Egyptian literature includes monographs on both animal and human diseases. Evidence of the parallel development of human and veterinary medicine is found in the writings of Hippocrates on medicine and of Aristotle, who described the symptomatology and therapy of the diseases of animals, including man. Early Greek scholars, noting the similarities of medical problems among the many animal species, taught both human and veterinary medicine. In the late 4th century BC, Alexander the Great designed programs involving the study of animals, and medical writings of the Romans show that some of the most important early observations on the natural history of disease were made by men who wrote chiefly about agriculture, particularly the aspect involving domesticated animals.

Most of the earliest suggestions of relationships between human health and animal diseases were part of folklore, magic, or religious practice. The Hindu's concern for the well-being of animals, for example, originated in his belief in reincarnation. From the pre-Christian Era to about 1500, the distinctions between the practices of human and veterinary medicine were not clear-cut; this was especially true in the fields of obstetrics and orthopedics, in which animal doctors in rural areas often delivered babies and set human-bone fractures. It was realized, however, that training in one field was inadequate for practicing in the other, and the two fields were separated.

Veterinary literature from the civilizations of Greece and Rome contains reference to "herd factors" in disease; contagion within groups of animals kept together, therefore, was recognized, and both quarantine and slaughter were used to control outbreaks of livestock diseases. Rinderpest (cattle plague) was the most important livestock disease from the 5th century until control methods were developed. Serious outbreaks of the disease prompted the

founding of the first veterinary college (École Nationale Vétérinaire), in Lyon, France, in 1762. Many aspects of animal diseases are best understood in terms of population or herd phenomena; for example, herds of livestock, rather than individual animals, are vaccinated against specific diseases, and housing, nutrition, and breeding practices are related to the likelihood of illness in the herd.

Pasteur's impact

The work of Pasteur was of fundamental significance to general medicine and to agriculture. Veterinarians became concerned with foods of animal origin after the discovery of microorganisms and their identification with diseases in man and other animals. Efforts were directed toward protecting humans from diseases of animal origin, primarily those transmitted through meat or dairy products. Modern principles of food hygiene, first established for the dairy and meat-packing industries in the 19th and early 20th centuries, have been generally applied to other food-related industries. The veterinary profession, especially in Europe, assumed a major role in early food-hygiene programs.

Since World War II, the eradication of animal diseases, rather than their control, has become increasingly important, and conducting basic research, combatting zoonoses, and contributing to man's food supply have become indispensable services of veterinary medicine.

IMPORTANCE

Economic importance. About 50 percent of the world's population suffers from chronic malnutrition and hunger. Inadequate diet claims many thousands of lives each day. When the lack of adequate food to meet present needs for an estimated world population of more than 4,600,000,000 in the 1980s is coupled with the prediction that the population may increase to 7,000,000,000 by the year 2000, it becomes obvious that animal-food supplies must be increased. One way in which this might be accomplished is by learning to control the diseases that afflict animals throughout the world (see Table 11), especially in the developing nations of Asia and Africa, where the population is expanding most rapidly. Most of the information concerning animal diseases, however, applies to domesticated animals such as pigs, cattle, and sheep, which are relatively unimportant as food sources in these nations. Remarkably little is known of the diseases of the goat, the water buffalo, the camel, the elephant, the yak, the llama, or the alpaca; all are domesticated animals upon which the economies of many developing countries depend. It is in these countries that increased animal production resulting from the development of methods for the control and eradication of diseases affecting these animals is most urgently needed.

Despite the development of various effective methods of disease control, substantial quantities of meat and milk are lost each year throughout the world. In countries in which animal-disease control is not yet adequately developed, the loss of animal protein from disease is about 30 to 40 percent of the quantity available in certain underdeveloped areas. In addition, such countries also suffer losses resulting from poor husbandry practices.

Role in human disease. Animals have long been recognized as agents of human disease. Man has probably been bitten, stung, kicked, and gored by animals for as long as he has been on earth; in addition, early man sometimes became ill or died after eating the flesh of dead animals. In more recent times, man has discovered that many invertebrate animals are capable of transmitting causative agents of disease from man to man or from other vertebrates to man. Such animals, which act as hosts, agents, and carriers of disease, are important in causing and perpetuating human illness. Because about three-fourths of the important known zoonoses are associated with domesticated animals, including pets, the term zoonoses was originally defined as a group of diseases that man is able to acquire from domesticated animals. But this definition has been modified to include all human diseases (whether or not they manifest themselves in all hosts as apparent diseases) that are acquired from or transmitted to any other vertebrate animal. Thus, zoonoses are naturally occurring infections and infestations shared by man and other vertebrates. Although the role of domesticated animals in many zoonoses is understood, the role of the numerous species of wild animals with which man is less intimately associated is not well understood. The discovery that diseases such as yellow fever, viral brain infections, plague, and numerous other important diseases involving man or his domesticated animals are fundamentally diseases of wildlife and exist independently of man and his civilization, however, has increased the significance of studying the nature of wildlife diseases. Table 10 contains a partial list of zoonoses, including the causative agents and the animals involved.

Role of domesticated animals

Animals in research: the biomedical model. Although in modern times the practice of veterinary medicine has been separated from that of human medicine, the observations of the physician and the veterinarian continue to add to the common body of medical knowledge. Of the more than 1,200,000 species of animals thus far identified, only a few have been utilized in research, even though it is likely that, for every known human disease, an identical or similar disease exists in at least one other animal species. Veterinary medicine plays an ever-increasing role in the health of man through the use of animals as biomedical models with similar disease counterparts in man. This use of animals as models is important because research on many genetic and chronic diseases of man cannot be carried out using humans.

Importance of animals in research

Hundreds of thousands of mice and monkeys are utilized each year in research laboratories in the U.S. alone. Animal studies are used in the development of new surgical techniques (*e.g.,* organ transplantations), in the testing of new drugs for safety, and in nutritional research. Animals are especially valuable in research involving chronic degenerative diseases because they can be induced experimentally in them with relative ease. The importance of chronic degenerative diseases, such as cancer and cardiovascular diseases, has increased in parallel with the growing number of communicable diseases that have been brought under control. See Table 2 for a list of animals with diseases similar to those that occur in man.

Examples of animal diseases that are quite similar to commonly occurring human diseases include chronic emphysema in the horse; leukemia in cats and cattle; muscular dystrophies in chickens and mice; atherosclerosis in pigs and pigeons; blood-coagulation disorders and nephritis in dogs; gastric ulcers in swine; vascular aneurysms (permanent and abnormal blood-filled area of a blood vessel) in turkeys; diabetes mellitus in Chinese hamsters; milk allergy and gallstones in rabbits; hepatitis in dogs and horses; hydrocephalus (fluid in the head) and skin allergies in many species; epilepsy in dogs and gerbils; hereditary deafness in many small animals; cataracts in the eyes of dogs and mice; and urinary stones in dogs and cattle.

The study of animals with diseases similar to those that affect man has increased knowledge of the diseases in man; knowledge of nutrition, for example, based largely on the results of animal studies, has improved the health of animals, including man. Animal investigations have been used extensively in the treatment of shock, in open-heart surgery, in organ transplantations, and in the testing of new drugs. Other important contributions to human health undoubtedly will result from new research discoveries involving the study of animal diseases.

ROLE OF ECOLOGY

Epidemiology, the study of epidemics, is sometimes defined as the medical aspect of ecology, for it is the study of diseases in animal populations. Hence the epidemiologist is concerned with the interactions of organisms and their environments as related to the presence of disease. The multiple-causality concept of disease embraced by epidemiology involves combinations of environmental factors and host factors, in addition to the determination of the specific causative agent of a given disease. Environmental factors include geographical features, climate, and concentration of certain elements in soil and water. Host factors include age, breed, sex, and the physiological state of an animal as well as the general immunity of a herd resulting from previous contact with a disease. Epidemiology, therefore, is concerned with the determination of

Table 2: A Partial List of Biomedical Models in Veterinary Medicine

animal disease (model)	animal affected	human counterpart disease
Cardiovascular system diseases		
Hereditary lymphedema	dog	Milroy's disease
Elevated blood pressure	mouse	hypertension
Atherosclerosis	swine	atherosclerosis
Periarteritis nodosa	cattle	periarteritis nodosa
Dissecting aneurysms	turkey	aneurysm
High-altitude disease	cattle	right ventricular hypertrophy
Endocardial fibroelastosis	dog	endocardial fibroelastosis
Heart failure	dog	congestive heart failure
Congenital lymphatic edema	swine	lymphatic edema
Endocrine system diseases		
Diabetes mellitus	Chinese hamster	diabetes mellitus
Antidiuretic-hormone deficiency	mouse	diabetes insipidus
Polyuria	Chinese hamster	diabetes insipidus
Congenital goitre	cattle	goitre
Adrenal cortical hypertrophy	dog	hyperadrenocorticism
Snell's dwarf	mouse	thyrotropin deficiency
Adenohypophyseal aplasia	cattle	adenohypophyseal aplasia
Hyperinsulinism	dog	hyperinsulinism
Familial "adiposity"	mouse	obesity
Acetonemia	cattle	ketosis
Early senility	Syrian hamster	aging
Gastrointestinal system diseases		
Esophageal achalasia	dog	achalasia
Cleft palate	horse	cleft palate
Gastric ulcer	swine	gastric ulcer
Regional ileitis	swine	regional ileitis
Granulomatosis colitis	boxer dog	ulcerative colitis
Acute hemorrhagic colitis	rabbit	hemorrhagic colitis
Megacolon	mouse	megacolon
Pancreatitis	dog	pancreatitis
Liver diseases		
Viral hepatitis	subhuman primate	viral hepatitis
Serum hepatitis	horse	transfusion hepatitis
Dubin–Johnson syndrome	sheep	Dubin–Johnson syndrome
Congenital photosensitivity and hyperbilirubinemia	Southdown sheep	Gilbert's syndrome
Nonhemolytic hyperbilirubinemia	rat	Crigler–Najjar syndrome
Pigmentary liver disease	howler monkey	hepatocellular melanosis
Hepatorenal syndrome	dog	hepatorenal syndrome
Hepatic coma	horse	hepatic coma
Glycogen-storage syndrome	dog	von Gierke's syndrome
Lantana camara poisoning	sheep	kwashiorkor
Pyrrolizidine plant alkaloids	cattle	veno-occlusive disease
Hemopoietic system diseases		
Congenital erythrocytic porphyria (recessive)	cattle	congenital erythrocytic porphyria
Congenital porphyria (dominant)	cat	erythrocytic porphyria
Hereditary leukomelanopathy	mink	Chediak–Higashi syndrome
Pelger–Huët anomaly	cattle	Pelger–Huët anomaly
Cyclic neutropenia	dog	cyclic neutropenia
Aleutian disease	mink	multiple myeloma
Abnormal lipid in lymphoid tumours	mouse	Niemann–Pick disease
Viral leukemia	cat	lymphocytic leukemia
Multiple myeloma	dog	multiple myeloma
Bialbuminemia	swine	bialbuminemia
Hemophilia (factor VIII)	dog	hemophilia
Factor VII deficiency	dog	factor VII deficiency
Hemophilia-B-like disease	dog	Christmas disease
Hertwig's anemia	mouse	macrocytic anemia
Malaria	penguin	malaria
In vitro sickling of erythrocytes	deer	sickle-cell anemia
Muscle diseases		
Hereditary muscular dystrophy	chicken	muscular dystrophy
Muscle diseases (cont.)		
Polymyopathy	Syrian hamster	muscular dystrophy
Muscular dysgenesis	mouse	prenatal muscle degeneration
Nutritional muscular dystrophy	sheep	muscular dystrophy
Paralytic myoglobinuria	horse	paroxysmal myoglobinuria
Myoclonia congenita	swine	myotonia congenita
Nervous system diseases		
Cerebellar hypoplasia	cat	cerebellar hypoplasia
Nigropallidal encephalomalacia	horse	Parkinson's disease
Hydrocephalus	rabbit	hydrocephalus
Leukoencephalosis	mouse	dystrophy of white matter
Globoid leukodystrophy	dog	globoid leukodystrophy
Grand-mal seizures	gerbil	epilepsy
Lipodystrophy	dog	familial amaurotic idiocy
Scotty cramps	dog	neurogenic muscular cramps
Milk fever	cattle	hypocalcemia
Trembler mutation	mouse	tremours
Hereditary ataxia	calf	ataxia
Congenital myotonia	goat	myotonia
Eye and ear diseases		
Hereditary deafness	cat	deafness
Cochlear degeneration	mouse	cochlear degeneration
Hypoplasia of organ of Corti	dog	hypoplasia of organ of Corti
Hereditary glaucoma	rabbit	glaucoma
Inherited cataract	cattle	cataract
Hereditary iridal heterochromia	cattle	iridal heterochromia
Congenital retinal dysplasia	dog	retinal dysplasia
Retinal dystrophy	mouse	pigmented retina
Diabetic microaneurysms	dog	diabetic microaneurysms
Reproductive system diseases		
Toxemia of pregnancy	guinea pig	toxemia of pregnancy
Prolonged gestation	cattle	prolonged gestation
Uterine cystic hyperplasia	mouse	uterine cystic hyperplasia
Prostatic hyperplasia	canine	prostatitis
Cryptorchidism	swine	cryptorchidism
Respiratory system diseases		
Acute pulmonary emphysema	cattle	pulmonary emphysema
Chronic pulmonary emphysema	horse	pulmonary emphysema
Pulmonary adenomatosis	cattle	adenomatosis
Pneumonia	dog	Hecht's pneumonia
Induced lung tumours	mouse	lung tumours
Skeletal system diseases		
Osteodystrophy	primate	fibrous osteodystrophy
Familial osteoporosis	dog	osteogenesis imperfecti
Senile osteoporosis	mouse	senile osteoporosis
Achondroplasia	rabbit	dwarfism
Intervertebral-disk syndrome	dog	disk luxation
Hip dysplasia	dog	acetabular dysplasia
Clubfoot	mouse	clubfoot
Skin diseases		
Baldness, male pattern	stumptail macaque	baldness, male pattern
Albinism	mouse	albinism
Genetic hypotrichosis	cattle	hypotrichosis
Hyperkeratosis	cattle	hyperkeratosis
Cutis hyperelastica	dog	Ehlers–Danlos disease
Seborrheic dermatitis	dog	seborrheic dermatitis
Impetigo	dog	impetigo
Milia	dog	milia
Urinary system diseases		
Diabetes insipidus	mouse	diabetes insipidus
Cystinuria	blotched genet	cystinuria
Chronic interstitial nephritis	dog	uremia
Cystic or absent kidneys	rat	cystic kidneys
Renal amyloidosis	mouse	renal amyloidosis
Cloisonné kidneys	goat	renal hemosiderosis

the individual animals that are affected by a disease, the environmental circumstances under which it may occur, the causative agents, and the ways in which transmission occurs in nature. The epidemiologist, who utilizes many scientific disciplines (*e.g.*, medicine, zoology, mathematics, anthropology), attempts to determine the types of diseases that exist in a specific geographical area and to control them by modifying the environment.

Diseases in animal populations are characterized by certain features. Some outbreaks are termed sporadic diseases because they appear only occasionally in individuals within an animal population. Diseases normally present in an area are referred to as endemic, or enzootic, diseases, and they usually reflect a relatively stable relationship between the causative agent and the animals affected by it. Diseases that occasionally occur at higher than normal rates in animal populations are referred to as epidemic, or epizootic, diseases, and they generally represent an unstable relationship between the causative agent and affected animals.

Sporadic and endemic diseases

The effect of diseases on a stable ecological system, which is the result of the dominance of some plants and animals and the subordination or extinction of others, depends on the degree to which the causative agents of diseases and their hosts are part of the system. Epidemic diseases result from an ecological imbalance; endemic diseases often represent a balanced state. Ecological imbalance and, hence, epidemic disease may be either naturally caused or induced by man. A breakdown in sanitation in a city, for example, offers conditions favourable for an increase in the rodent population, with the possibility that diseases such as plague may be introduced into and spread among the human population. In this case, an epidemic would result as much from an alteration in the environment as from the presence of the causative agent *Pasteurella pestis,* since, in relatively balanced ecological systems, the causative agent exists enzootically in the rodents (*i.e.,* they serve as reservoirs for the disease) and seldom involves man. In a similar manner, an increase in the number of epidemics of viral encephalitis, a brain disease, in man has resulted from the ecological imbalance of mosquitoes and wild birds caused by man's exploitation of lowland for farming. Driven from their natural habitat of reeds and rushes, the wild birds, important natural hosts for the virus that causes the disease, are forced to feed near farms; mosquitoes transmit the virus from birds to cattle and man.

Detection and diagnosis

REACTIONS OF TISSUE TO DISEASE

As previously noted, disease may be defined as an injurious deviation from a normal physiological state of an organism sufficient to produce overt signs, or symptoms. The deviation may be either an obvious organic change in the tissue comprising an organ or a functional disturbance whose organic changes are not obvious. The severity of the changes that occur in cells and tissues subjected to injurious agents is dependent upon both the sensitivity of the tissue concerned and the nature and time course of the agent. A mildly injurious agent that is present for short periods of time may either have little effect or stimulate cells to increased activity. Strongly injurious agents in prolonged contact with cells cause characteristic changes in them by interfering with normal cell processes. Most causative agents of disease fall into the latter category. Causative agents and some of the symptoms of many of the diseases mentioned in this section are found in Tables 3 through 8.

Degeneration and infiltration

Characteristics of cell and tissue changes. Changes in cells and tissues as a result of disease include degenerative and infiltrative changes. Degenerative changes are characterized by the deterioration of cells or a tissue from a higher to a lower form, especially to a less functionally active form. When chemical changes occur in the tissue, the process is one of degeneration. When the changes involve the accumulation of materials within the cells comprising tissues, the process is called infiltration. Diseases such as pneumonia, metal poisoning, or septicemia (the persistence of disease-causing bacteria in the bloodstream) may cause the mildest type of degeneration—parenchymatous changes, or cloudy swelling of the cells; the cells first affected are the specialized cells of the liver and the kidney. Serious cellular damage may cause the uptake of water by cells (hydropic degeneration), which lose their structural features as they fill with water. The causes for the accumulation in cells of abnormal amounts of fats (fatty infiltration and degeneration) have not yet been established with certainty but probably involve fat metabolism. Poisons such as phosphorus may cause sudden increases in the accumulation of fats in the liver. An abnormal protein material may accumulate in connective-tissue components of small arteries as a result of chronic pneumonia, chronic bacterial infections, and prolonged antitoxin production (in horses); the condition is known as amyloid degeneration and infiltration. Hyaline degeneration, characterized by tissues that become clear and appear glasslike, usually occurs in connective-tissue components of small blood vessels as a result of conditions that may occur in kidney structures (glomeruli) of animals with nephritis or in lymph glands of animals with tuberculosis. Certain structures (glomeruli) of animals with nephritis result in degeneration.

The condition in which mucus, a secretion of mucous membranes lining the inside surfaces of organs, is produced in excess and accumulates in greater than normal amounts is referred to as mucoid degeneration. Major causes of this condition include chronic irritation of mucous membranes and certain mucus-producing tumours. Abnormal amounts of glycogen, which is the principal storage carbohydrate of animals, may occur in the liver as a result of certain inherited diseases of animals; the condition is known as glycogen infiltration. The abnormal deposition of calcium salts, which is known as hypercalcification, may occur as a result of several diseases involving the blood vessels and the heart, the urinary system, the gallbladder, and the bonelike tissue called cartilage. Pigments (coloured molecules) from coal dust or asbestos dust may infiltrate the lungs of certain dogs in two types of lung disease: anthracosis and asbestosis. Abnormal amounts of iron-containing coloured molecules (hemosiderin) resulting from the breakdown of hemoglobin, the oxygen-carrying protein of red blood cells, are often deposited in the liver and the spleen after diseases that involve excessive breakdown of red blood cells. A dark-coloured molecule (melanin) occurs abnormally in the livers of certain sheep suffering from Dubin–Johnson syndrome and in certain tumours called melanomas. Uric acid infiltration, which occurs in poultry, is characterized by the deposition of uric acid salts.

Necrosis, the death of cells or tissues, takes place if the blood supply to tissues is restricted; poisons produced by microbes, chemical poisons, and extreme heat or electricity also may cause necrosis. The rotting of the dead tissue is known as gangrene.

Atrophy of animal tissue involves a process of tissue wasting, in which a decrease occurs in the size or number of functional cells—*e.g.,* in inherited muscular dystrophy of chickens. Hypertrophy—an increase in the size of the cells in a tissue or an organ—occurs in heart muscle during diseases involving the heart valves, in certain pneumonias, and in some diseases of the endocrine glands. Aplasia is the term used when an entire organ is missing from an animal; hypoplasia indicates arrested or incomplete development of an organ, and hyperplasia an increase in the production of the number of cells—*e.g.,* the persistent callus that forms on the elbows of some dogs. Metaplasia is used to describe the change of one cell type into another; it may occur in chronic irritation of tissues and in certain cancerous tumours.

Characteristics of inflammatory reactions. When tissues are injured, they become inflamed. The inflammation may be acute, in which case the inflammatory processes are active, or chronic, in which case the processes occur slowly and new connective tissue is formed. The reaction of inflamed tissues is a combination of defensive and repair mechanisms. Acute inflammation is characterized by redness, heat, swelling, sensitivity, and impaired function. Several types of acute inflammation are known. Mild acute inflammations of mucous membranes resulting in the production of thin watery material (exudate) are called catarrhal inflammations; parenchymatous inflammations occur in organs undergoing degeneration. If the exudate formed in response to an injury is of a serous nature—that is, resembling blood plasma—the process is called serous inflammation. In fibrinous inflammation, a protein (fibrin) forms on membranes, including those in the lungs. In suppurative inflammation, dead tissue is replaced with pus composed of colourless blood cells (leucocytes) and tissue juices.

During the inflammatory reaction, the injured tissue is surrounded by an area of rapidly dividing cells. Specialized cells called macrophages enter the tissue and remove blood and tissue debris. Other cells, called neutrophils, ingest disease-causing bacteria and other foreign material. In chronic inflammations, the connective tissue contains fibroblasts, cells that divide and form new connective, or scar, tissue.

Table 3: Selected Infectious and Parasitic Diseases of Animals

animal(s) affected	name(s) of disease	causative organism	nature of disease
Diseases of bacterial origin			
Most mammals, chickens	necrobacillosis, calf diptheria, bovine foot rot, necrotic hepatitis, dermatitis	*Sphaerophorus necrophorus*	organism invades tissue and causes tissue death (necrosis) after other wounds or infections have occurred; *i.e.*, disease is known as a secondary infection
Cattle, sheep, horses, chickens, man, many other animals	botulism	toxins produced by *Clostridium botulinum*	results from eating toxins released in decayed or spoiled foods; toxins cause rapid paralysis of nerves in throat and all muscles, almost always fatal
Swine, cattle, sheep, goats, rabbits, man, dogs, many other animals	listeriosis, circling disease, meningoencephalitis	*Listeria monocytogenes*	symptoms vary in affected animal; organism may affect the central nervous system (brain, spinal cord) or the membranes surrounding it or cause necrosis of heart muscles, localized tissue death in liver, or a septicemia (persistence of bacteria in the bloodstream)
Swine, cattle, sheep, goats, horses, turkeys, man	erysipelas, diamond-skin disease	*Erysipelothrix insidiosa*	manifestations include septicemia and pathological discontinuities of tissue (lesions) in skin, heart, joints (in swine); arthritis (in sheep, occasionally in cattle, horses, goats); septicemia and death (in turkeys); skin lesions (in man)
Cattle, sheep, goats, horses, mules	anthrax, splenic fever, charbon	*Bacillus anthracis*	spores (inactive forms) of organisms in soil, transmitted through insect bites or food; manifestations include hemorrhage and edema (accumulation of fluid) in tissues
Swine, cattle, sheep, horses, mules	malignant edema, gas gangrene	*Clostridium septicum*	spores enter from dirt into injured tissue, cause severe gangrene (rotting of dead tissue), swelling; prognosis (outlook) poor
Swine, cattle, sheep, goats	pyobacillosis	*Corynebacterium pyogenes*	characterized by multiple abscesses (localized collections of pus) throughout the body; may result in debilitation (including arthritis in swine) and death
Primarily swine, cattle, goats (secondarily in man and other animals)	brucellosis, Bang's disease, contagious abortion; undulant fever, Malta fever (in man)	*Brucella abortus, B. melitensis, B. suis.*	primarily affects genital organs in both sexes; may cause abortion, sterility, infection of fetus in female, local lesions in various tissues; pasteurization of milk has controlled the disease in man
Swine, cattle, sheep	shipping fever, pasteurellosis, hemorrhagic septicemia	*Pasteurella multocida* and *P. hemolytica;* also in conjunction with viral agents	causes of great economic losses throughout the world; manifestations may include acute to chronic respiratory disease; the various causative organisms vary in virulence (degree of pathogenicity); an acute form (*i.e.*, short, severe) affects rabbits
Horses, mules, donkeys (man less susceptible)	glanders, farcy, malleus	*Malleomyces mallei*	organisms enter animal through digestive tract, travel via blood to lungs, trachea, and skin, and form ulcers; an acute form causes death, a chronic type may persist for years; human infections occur from exposure of broken skin to affected animals
Horses (mules, donkeys less susceptible)	strangles, distemper, infectious adenitis	*Streptococcus equi*	most common in young, undernourished horses in crowded conditions; manifested by high temperature, nose infections, and abscesses in lymph glands of neck
Horses	purpura hemorrhagica, petechial fever	unknown, but associated with *Streptococcus equi*	noncontagious, follows acute infections and toxemias; characterized by generalized hemorrhages in tissues and the accumulation of fluid (edema); relapses often occur
Primarily horses	ulcerative lymphangitis or cellulitis	*Corynebacterium pseudotuberculosis*	chronic disease, develops slowly following the entrance of bacteria through skin; affects hindlegs, sometimes severely
Horses (males most susceptible); sometimes swine, cattle; rarely dogs or cats	tetanus, lockjaw	toxins produced by *Clostridium tetani*	bacteria enter tissue at time of injury, produce toxins in necrotic tissue; affected animals become stiff; death results from suffocation
Swine	streptococcal infection	*Streptococcus* species	younger pigs more easily infected; symptoms varied (*e.g.*, septicemia, arthritis, uterine inflammation, middle-ear infection, multiple abscesses)
Swine, accidentally in other animals	salmonellosis, enteritis, swine typhoid	*Salmonella choleraesuis*	may be acute (*i.e.*, have a short, severe course) or chronic (persists for a long time); symptoms include loss of weight, sometimes acute septicemia
Swine, cattle	actinobacillosis, botryomycosis, big head	*Actinobacillus lignieresii*	organism a normal inhabitant of mouth, enters tissues through ulcers or wounds; symptoms include abscesses
Cattle	leptospirosis, hemoglobinuria	*Leptospira* species	symptoms of acute form include abortion, bloody milk, hemoglobin (blood pigment) in urine, kidney disease, and destruction of red blood cells; a milder form also exists
Cattle	infectious bovine pyelonephritis, infectious cystitis	*Corynebacterium renale*	usually observed in pregnant cattle in winter; a slowly developing disease that affects kidneys and bladder
Primarily cattle (rarely man, swine, sheep, horses)	tuberculosis, pearly disease	*Mycobacterium tuberculosis*	a chronic disease characterized by lesions, usually in lungs and lymph nodes, but sometimes in many other organs
Cattle (rarely sheep)	bacillary hemoglobinuria, red water disease	*Clostridium hemolyticum*	spores eaten with food, develop into active cells, migrate to liver, and produce infarcts (tissue death); usually fatal within 36 hours

Table 3: Selected Infectious and Parasitic Diseases of Animals (continued)

animal(s) affected	name(s) of disease	causative organism	nature of disease
Cattle, sheep	pinkeye, infectious keratitis, kerato-conjunctivitis	*Moraxella bovis* (in cattle), *Colesiota conjunctivae* (in sheep)	affects eyes; may result in blindness; a very contagious disease whose spread may be influenced by dust irritation or possibly by viral invasion
Cattle, sheep	Johne's disease, paratuberculosis	*Mycobacterium paratuberculosis*	a chronic disease; causes diarrhea, progressive weight loss
Cattle, sheep	vibriosis, epizootic abortion	*Vibrio fetus*	a venereal disease (*i.e.*, transmitted by sexual contact) in cattle; transmitted in contaminated food and water in sheep; commonly results in infertility or abortion in cattle, abortion in sheep
Cattle, sheep (occasionally swine, goats, deer, horses)	blackleg, black quarter, quarter ill	*Clostridium feseri* (*chauvoei*)	spores transmitted from soil to animal through wounds or cuts; symptoms include lameness, gangrene of affected tissues (usually in leg muscles); usually fatal
Sheep	enterotoxemia, overeating disease, pulpy kidney	*Clostridium perfringens* type D	affected lambs usually fat or feeding on rich clover pasture; usually fatal within a day from acute toxemia (absorption of bacterial toxins)
Primarily sheep	pseudotuberculosis, caseous lymphadenitis	*Corynebacterium ovis*	organisms transmitted to animal through breaks in the skin; slowly developing abscesses (usually in lungs or lymph nodes) may rupture and spread throughout body
Sheep, goats (occasionally cattle)	black disease, infectious necrotic hepatitis	*Clostridium novyi*	organisms probably present normally in intestinal tract, associated with fluke (parasitic worm) movements in liver; produce liver damage, toxemia, and death
Diseases of viral origin			
Mammals	rabies, hydrophobia, lyssa, mad dog, le Rage	rabies virus	transmitted primarily through the bite of a rabid animal; wild animals (*e.g.*, skunks, squirrels, bats) a reservoir for infection; disease characterized by central-nervous-system symptoms (*e.g.*, rage, excitability; paralysis of jaw with salivation), general paralysis, and death
Mammals (especially cattle)	bovine warts, papillomatosis	papilloma viruses	warts of variable size develop, usually on sides of head and neck of cattle, sometimes on sex organs
Many mammals (*e.g.*, swine, cattle, sheep, goats, horses)	pox, variola	pox virus	often an acute highly infectious disease, characterized by formation of papules (small solid elevations), vesicles (small liquid-containing sacs), and pustules (small pus-filled elevations) on the skin
Swine, cattle (also rats, dogs, cats)	pseudorabies, Aujeszky's disease, mad itch	pseudorabies virus	affected animals rub body parts, undergo spasmodic muscle contractions; froth at the mouth; and show nervous irritability; usually fatal
Young pigs	transmissible gastroenteritis (TGE)	TGE virus	acute and fatal to pigs less than two to three weeks old; virus attacks absorptive surfaces of small intestine
Swine	hog cholera, swine fever, swine pest	hog-cholera virus	infectious disease; may be acute or chronic; spread by flies, animal contact, garbage, contaminated pastures; symptoms include high fever, severe hemorrhages in skin and organs
Swine	vesicular exanthema (VE)	VE virus	vesicles form on snout, mouth, abdominal wall; foot lesions occur; highly infectious, spread through animal contact or raw pork scraps in garbage; fatal usually only in young pigs
Swine, ferrets, mice	swine influenza, hog flu	swine-influenza virus; bacterium; *Hemophilus suis*	acute contagious disease; virus enters animal through lungworm larvae, acute infection occurs if *Hemophilus* organisms are in lung; symptoms include fever, pneumonia, bronchitis
Swine, cattle, horses	vesicular stomatitis (VS), mouth thrush	VS virus	effects varied; *e.g.*, high fever, salivation, vesicles in mouth region, lack of appetite (in horses); inflammation of mammary glands, vesicles in mouth region, inflammation of feet (in cattle); snout and mouth lesions, severe feet involvement (in swine)
Cattle	sporadic bovine encephalomyelitis (SBE), Buss disease	SBE virus	weakens calves; an infection of brain and membranes of brain and spinal cord; recovery often occurs
Cattle	infectious bovine rhinotracheitis (IBR), red nose, pinkeye, dust pneumonia	IBR virus	acute infection followed by secondary bacterial infections (*Pasteurella multocida*, *Spherophorus necrophorus*) in lungs, sex organs, eye; nostrils swell, become red
Cattle, buffalo, deer	malignant catarrhal fever (MCF), head catarrh, snotsiekte, epitheliosis	MCF virus	numerous symptoms include rapid weight loss, eye lesions, nasal discharge, muscular twitching, convulsions; usually fatal
Cattle, sheep	bluetongue, soremuzzle, catarrhal fever	bluetongue virus	virus transmitted through gnats (small flies); a serious problem in sheep; numerous symptoms; recovery very slow; usually less than 10 percent mortality of a flock
Sheep (also transmissible to cows)	ovine virus abortion (OVA), enzootic abortion	OVA virus	causes economic losses through abortion, weak lambs, and poor breeding efficiency

Table 3: Selected Infectious and Parasitic Diseases of Animals (continued)

animal(s) affected	name(s) of disease	causative organism	nature of disease
Sheep, goats, man	contagious ecthyma (CE), sore mouth, doby mouth, orf, pustular dermatitis	CE virus	udder, lips, and nose of sheep affected; secondary bacterial invasion may result in death, but animals usually recover
Horses	equine infectious anemia (EIA), swamp fever, malarial fever	EIA virus	transmitted by mosquitoes, lice, flies, and hypodermic needles; either acute, chronic, or latent (not manifest); varied symptoms include intermittent fever, loss of weight, jaundice, hemorrhages, anemia, and fluid in body cavities
Horses	equine viral arteritis (EVA), infectious arteritis	EVA virus	an acute contagious disease similar to EVR in symptomatology but causes damage to small arteries
Horses, mules, man, laboratory animals	equine encephalomyelitis (EE), sleeping sickness, viral encephalitis	EE virus	many viral strains transmitted by an insect (usually mosquitoes or mites or ticks); disease causes inflammation of brain cells; the many symptoms include death; inapparent infections occur in chickens, pigeons, and pheasants
Horses (also guinea pigs, mice, hamsters)	equine viral rhinopneumonitis (EVR), equine virus abortion	EVR virus	disease highly contagious; symptoms include high fever, mild upper-respiratory involvement, and usually abortion with liver damage of fetus in pregnant mares
Diseases of fungal origin			
Many domestic, laboratory, and wild mammals	histoplasmosis, reticuloendothelial cytomycosis	*Histoplasma capsulatum*	chronic; may resemble tuberculosis; granulomas (tumours) in lungs, liver, and spleen; intestinal involvement in dogs results in diarrhea
Swine, cattle, sheep, horses, fowl, dogs, cats	ringworm, tinea, trichophytosis	*Trichophyton* and *Microsporum* species	infectious skin disease caused by invasion of hair follicles; characterized by round crusty lesions, inflammation
Swine, cattle, horses (man secondarily)	actinomycosis, lumpy jaw, wooden tongue	*Actinomyces bovis*	cattle manifest a bonelike swelling on upper or lower jaw; swine manifest a tumourlike enlargement of udder caused by infections from teeth of suckling pigs
Cattle, horses, cats, dogs, man	cryptococcosis	*Cryptococcus neoformans*	usually caused by inhalation of contaminated dust; lungs affected primarily; disease may spread to almost any organ
Cattle, sheep, dogs, man	coccidioidomycosis coccidioidal granuloma, San Joaquin Valley fever	*Coccidioides immitis*	in the acute respiratory form, symptoms include cough, with recovery in two weeks; in the more serious chronic form, gradual loss in weight, abscesses, and granulomas in various tissues, including skin, occur
Primarily horses and man	sporotrichosis	*Sporotrichum schenckii*	occurs first as ulcers on skin, invasion of the lymph glands occurs, may spread throughout circulatory system
Diseases of rickettsial origin			
Swine	eperythrozoonosis, ictero-anemia, yellow-belly	*Eperythrozoon suis*	organisms cause red-blood-cell destruction; both acute and mild forms; many animals with a mild form act as carriers
Cattle	anaplasmosis, South African gall sickness	*Anaplasma marginale*	infectious disease spread either by blood-sucking ticks, mosquitoes, flies, or by mechanical transmission (*e.g.*, resulting from dehorning, vaccination); symptoms usually include extreme anemia from destruction of red blood cells; recovered animals are immunological carriers
Diseases of protozoal origin			
Most animals (including man)	toxoplasmosis	*Toxoplasma gondii*	transmission not clear but probably occurs by contaminated food or direct contact; symptoms include weakness, respiratory problems, lack of coordination, nodules throughout body, enlarged lymph nodes, and tissue death; treatment difficult
Swine, cattle, sheep, goats	coccidiosis	*Eimeria zürnii, E. bovis,* and ten other species	causative organisms found in most mature animals; symptoms result in loss of large amounts of blood and dehydration; mortality may be as high as 50 percent
Cattle	trichomoniasis	*Trichomonas fetus*	transmitted by sexual contact or by artificial insemination, symptoms include abortion, failure to conceive, inflammation of uterus; no symptoms apparent in infected bull that acts as a carrier
Cattle	Texas fever, cattle-tick fever, babesiasis, piroplasmosis, red water	*Babesia bigemina*	organism, which destroys red blood cells, is transmitted by ticks (*Margaropus* species) and mechanical means (*i.e.*, surgical instruments, needles); symptoms include high fever, severe anemia, hemoglobin in urine; chronic forms occur; some animals act as carriers
Horses	dourine, equine syphilis, breeding disease	*Trypanosoma equiperdum*	transmitted by sexual contact or blood-sucking flies; affects sex organs, causes plaquelike areas on skin, paralysis of muscles, loss of condition
Horses, mules, donkeys	equine piroplasmosis, equine malaria, babesiasis	*Babesia caballi, B. equi*	acute cases may die quickly; animals with less acute forms have varied symptoms (*e.g.*, intermittent fever, jaundice, internal hemorrhages); anemia results from invasion of red blood cells by causative organisms; *B. equi* more pathogenic than *B. caballi*

Table 3: Selected Infectious and Parasitic Diseases of Animals (continued)

animal(s) affected	name(s) of disease	causative organism	nature of disease
Diseases of nematode (roundworm) origin			
Swine	lungworms	*Metastrongylus* species	common symptoms include coughing and lung irritation
Swine	kidney worms	*Stephanurus dentatus*	mature worms live in urinary tract; larvae migrate to liver, produce lesions and weight loss
Swine	intestinal roundworm	*Ascaris suum*	migrations of organisms through lungs cause hemorrhages and pneumonia, may interfere with bile flow and food absorption
Swine	intestinal threadworm	*Strongyloides*	migration of large numbers of larvae cause tissue damage
Cattle	stomach worms	*Ostertagia* and *Trichostrongylus* species	symptoms include anemia, stunted growth, and diarrhea
Cattle	nodular worm	*Oesophagostomum radiatum*	nodules form in tissues; poor intestinal absorption caused by larvae (immature forms of organism) and nodules results in diarrhea
Cattle	verminous pneumonia	*Dictyocaulus viviparus*	ingested infective larvae migrate to lungs, produce coughing, discomfort, and pneumonia
Sheep	lungworms	*Dictyocaulus filaria, Muellerius capillaris*	symptoms include formation of lung nodules, collapse of portions of lungs
Sheep	hookworms	*Bunostomum trigonocephalum*	bloodsucking hookworms cause anemia, intermittent diarrhea
Sheep	filarial dermatitis	*Elaeophora schneideri*	symptoms include skin lesions
Horses	oxyuriasis (pinworms)	*Oxyuris equi*	worms cause irritation in the area around the anus
Horses	ascariasis (intestinal roundworms)	*Parascaris equorum*	larval forms cause damage; symptoms include defective intestinal absorption
Horses	strongylosis	*Strongylus* species	large numbers of worms weaken foals (newborn horses); migrating larvae may cause formation of clots in blood vessels and lameness
Horses	habronemiasis (summer sores)	*Habronema* species	habronema larvae may enter skin wounds, causing granulation; eye and stomach inflammations also occur
Diseases of platyhelminth (flatworm) origin			
Sheep	tapeworm	*Moniezia expansa*	results in poor growth
Sheep	fringed tapeworm	*Thysanosoma actinoides*	causes digestive disturbances
Horses	tapeworm	*Anaplocephala perfoliata*	symptoms may include inflammation of gut and ulceration
Diseases of acanthocephalan (spiny-headed-worm) origin			
Swine	spiny-headed worm	*Macracanthorhynchus hirudinaceus*	nodules form on small intestine; may result in peritonitis (inflammation of lining of internal organs)
Diseases of arthropod origin			
Cattle	scabies (mange)	*Chorioptes bovis, Psoroptes equi, Sarcoptes scabiei* (mites)	contagious skin diseases
Cattle	grubs	*Hypoderma bovis* (heel fly)	migrating larvae produce tissue damage, cysts, and hide damage
Cattle	lice	*Linognathus vituli, Solenopotes capillatus, Haematopinus quadripertusis* (bloodsucking lice), *Bovicola bovis* (biting louse)	symptoms include dermatitis and anemia
Sheep	screwworm infestations	many fly larvae (*e.g., Cochliomyia hominivorax, Chrysomyia bezziana*)	flies lay eggs in open wounds; developing larvae (screwworms) burrow into tissue and destroy it
Sheep	psoroptic mange (sheep scab)	*Psoroptes communis* (mite)	all parts of skin inflamed, particularly those covered with wool

Hemorrhage and edema

Characteristics of circulatory disturbances. An increase in the rate of blood flow to a body part, which is referred to by the term congestion, or hyperemia, occurs during inflammation; a diminished blood flow to tissues is referred to by the term ischemia, or a local anemia. Examples of hemorrhage, the escape of blood from vessels, include epistaxis, or nosebleeds, in racehorses; hematemesis, or regurgitation of blood, in dogs with uremia; hemoptysis, or blood loss from lungs; hematuria, or blood in urine, of cattle with inflammation of the urinary bladder. Edema, a condition that is characterized by abnormal accumulations of fluid in tissues, occurs not only in a tissue during inflammation but also over the entire body if the concentration of blood-serum proteins, especially albumin, is low. A thrombosis, which is a blood clot in a blood vessel, may block or slow circulation of blood to tissues; if blood vessels become blocked, the condition is known as an embolism. The term infarction describes the necrosis that occurs in tissues whose blood supply is blocked by an embolism.

METHODS OF EXAMINATION

Before an unhealthy animal receives treatment, an attempt is made to diagnose the disease. Both clinical findings, which include symptoms that are obvious to a nonspecialist and clinical signs that can be appreciated only by a veterinarian, and laboratory test results may be necessary to establish the cause of a disease. A clinical examination should indicate if the animal is in good physical condition, is eating adequately, is bright and alert, and is functioning in an apparently normal manner. Many disease processes are either inflammatory or result from tumours. Malignant tumours (*e.g.,* melanomas in horses, squamous cell carcinomas in small animals) tend to spread rapidly and usually cause death. Other diseases cause the circulatory disturbances or the degenerative and infiltrative changes that are summarized in the preceding section. If a specific diagnosis is not possible, the symptoms of the animal are treated.

A case record of the information pertaining to an animal (or to a herd of animals) that is suspected of having a

Table 4: Examples of Noninfectious Diseases of Animals

animal(s) affected	name(s) of disease	nature of disease
Hereditary diseases		
Pigs, calves, foals	congenital absence of skin (epitheliogenesis imperfecti)	complete absence of skin over parts of body; fatal a few days after birth
Swine, cattle	congenital porphyria (pink tooth)	causes anemia, wine-coloured urine; results from a biochemical defect in the metabolism of a component (porphyrin) of the iron-containing pigment (hematin) of hemoglobin, the oxygen-carrying protein of blood
Cattle	prolonged gestation (prolonged pregnancy)	may cause a three-week to three-month delay in birth of calves, which when born are either large or deformed; a special type in Guernsey and Jersey breeds results in death of calves at birth
Metabolic diseases		
Cattle (rarely sheep and pigs)	milk fever (parturient paresis)	caused in lactating cattle by loss of calcium into the milk; low levels of calcium in blood cause muscular weakness, circulatory collapse, and loss of consciousness; treatment includes replacing calcium
Cattle, sheep	ketosis (acetonemia in cattle; pregnancy toxemia in sheep)	occurs in lactating cattle following calving and in sheep in terminal stage of pregnancy (both times of increased need for carbohydrates); causes paralysis and death; complex treatment includes replacing carbohydrates
Horses	azoturia (paralytic myoglobinuria)	paralytic disease of unknown cause; occurs during exercise following a period of inactivity; muscles degenerate; results in paralysis, dark-red urine
Functional diseases		
Cattle, sheep	kidney and bladder calculi (urolithiasis)	cattle eating range grasses with high silicon content may develop obstructions (solid masses containing silicon and protein) in urinary system; similar effects may occur with diets high in phosphate, in which case the solid mass contains magnesium ammonium phosphate and protein
Cattle, sheep	bloat (ruminal tympany)	distension (caused by gases) of first two stomachs of cows; conditions preventing eructation (belching) of gases are major causes; occurs primarily when cattle overeat on leguminous pastures (alfalfa and clovers); often fatal
Cattle, horses	pulmonary emphysema (heaves in horses)	acute form occurs in cattle, chronic form in horses; alveoli (small terminal air sacs) in lung rupture, reducing surface area for oxygen transport; causes not yet clear, but disease may follow pneumonia and allergic reactions
Nutritional deficiency diseases		
Most animals	vitamin A deficiency	caused by dietary insufficiency of vitamin A or substance from which vitamin A is formed (carotene); numerous manifestations in young and adult animals include night blindness
Pigs	iron deficiency	caused by insufficient iron in diet; manifestations include severe anemia and poor growth
Diseases caused by chemical agents		
Pigs, cattle, horses	bracken-fern poisoning	fern contains thiaminase, which destroys vitamin B_1 (thiamine), thereby producing a vitamin deficiency in horses and swine; in cattle the bone marrow is affected, and deficiency of blood cells and excessive hemorrhages occur
Cattle, sheep, horses	rye-grass staggers	manifestations include either liver degeneration and photosensitization or uncoordination, convulsions, and paralysis; cause not yet established, but fungus on the rye grass plays some role in the liver degeneration
Cattle (occasionally other animals)	sweet-clover poisoning	caused by eating moldy sweet-clover hay, which contains the anticoagulant compound dicoumarol; manifestations include extensive hemorrhages and severe blood loss after injury
Cattle, sheep	molybdenum poisoning	results if pasture soil contains toxic quantities (three parts per million) of molybdenum, which replaces copper in body; symptoms include diarrhea, loss of hair colour, anemia
Diseases caused by physical agents		
Cattle	hardware disease (traumatic reticuloperitonitis)	objects such as nails and small pieces of balling wire may be eaten with feed; perforation and inflammation of first stomach (reticulum) may occur; surgery sometimes necessary
Cattle	brisket disease (mountain sickness)	occurs in cattle at high altitudes where levels of atmospheric oxygen are too low to provide oxygen required; manifestations include enlargement of right heart, congestive heart failure

disease is begun at the time the animal is taken to a veterinarian (or the veterinarian visits the animal) and is continued through treatment. It includes a description of the animal (age, species, sex, breed); the owner's report; the animal's history; a description of the preliminary examination; clinical findings resulting from an examination of body systems; results of specific laboratory tests; diagnosis regarding a specific cause for the disease (etiology); outlook (prognosis); treatment; case progress; termination; autopsy, if performed; and the utilization of scientific references, if applicable.

The veterinarian must diagnose a disease on the basis of a variety of examinations and tests, since he obviously cannot interrogate the animal. Methods used in the preparation of a diagnosis include inspection—a visual examination of the animal; palpation—the application of firm pressure with the fingers to tissues to determine characteristics such as abnormal shapes and possible tumours, the presence of pain, and tissue consistency; percussion—the application of a short, sharp blow to a tissue to provoke an audible response from body parts directly beneath; auscultation—the act of listening to sounds that are produced by the body during the performance of functions (*e.g.*, breathing, intestinal movements); smells—the recognition of characteristic odours associated with certain diseases; and miscellaneous diagnostic procedures, such as eye examinations, the collection of urine, and heart, esophageal, and stomach studies.

General inspection. Deviation of various characteristics from the normal, observation of which constitutes the general inspection of an animal, is a useful aid in diagnosing disease. The general inspection includes examination of appearance; behaviour; body condition; respiratory movements; state of skin, coat, and abdomen; and various common actions.

The animal's appearance

The appearance of an animal may be of diagnostic significance; small size in a pig may result from retardation of growth, which is caused by hog-cholera virus (Table 3). Observation of the behaviour of an animal is of value in diagnosing neurological diseases; *e.g.*, muscle spasms occur in lockjaw (tetanus) in dogs, nervousness and convulsions in dogs with distemper (Table 5), dullness in horses with equine viral encephalitis (Table 3), and excitement in animals suffering from lead poisoning. Subtle behavioral changes may not be noticeable. The general condition of the body is of value in diagnosing diseases that cause excessive leanness (emaciation), including certain cancers, or other chronic diseases, such as a deficiency in the output

of the adrenal glands or tuberculosis. Defective teeth also may point to malnutrition and result in emaciation.

The respiratory movements of an animal are important diagnostic criteria; breathing is rapid in young animals, in small animals, and in animals whose body temperature is higher than normal. Specific respiratory movements are characteristic of certain diseases—*e.g.*, certain movements in horses with heaves (emphysema) or the abdominal breathing of animals suffering from painful lung diseases. The appearance of the skin and hair may indicate dehydration by lack of pliability and lustre; or the presence of parasites such as lice, mites, or fleas; or the presence of ringworm infections and allergic reactions by the skin changes they cause. The poisoning of sheep by molybdenum in their hay may be diagnosed by the loss of colour in the wool of black sheep. Distension of the abdomen may indicate bloat in cattle or colic in horses.

Abnormal activities may have special diagnostic meaning to the veterinarian. Straining during urination is associated with bladder stones; increased frequency of urination is associated with kidney disease (nephritis), bladder infections, and a disease of the pituitary gland (diabetes insipidus). Excessive salivation and grinding of teeth may be caused by an abnormality in the mouth. Coughing is associated with pneumonia. Some diseases cause postural changes: for example, a horse with tetanus may stand in a stiff manner. An abnormal gait in an animal made to move may furnish evidence as to the cause of a disease, as louping ill in sheep.

Clinical examination. Following the general inspection of an animal thought to have contracted a disease, a more thorough clinical examination is necessary, during which various features of the animal are studied. These include the visible mucous membranes (conjunctiva of the eye, nasal mucosa, inside surface of the mouth, and tongue); the eye itself; and such body surfaces as the ears, horns (if present), and limbs. In addition, the pulse rate and the temperature are measured.

Structural features involved

The veterinarian examines the visible mucous membranes of the eye, nose, and mouth to determine if jaundice, hemorrhages, or anemia are present. The conjunctiva, or lining of the eye, may exhibit pus in pinkeye infections, have a yellow appearance in jaundice, or exhibit small hemorrhages in certain systemic diseases. Examination of the nose may reveal ulcers and vesicles (small sacs containing liquid), as in foot-and-mouth disease, a viral disease of cattle, or vesicular exanthema, a viral disease of swine. Ulceration of the tongue may be apparent in animals suffering from actinobacillosis, a disease of bacterial origin (see Table 3).

A detailed examination of the eye may show abnormalities of the cornea resulting from such diseases as infectious hepatitis in dogs (Table 5), bovine catarrhal fever, and equine influenza. Cataract, a condition in which the passage of light through the lens of the eye is obstructed, may result from a disorder of carbohydrate metabolism (diabetes mellitus), infections, or a hereditary defect.

An elevated temperature, or fever, resulting from the multiplication of disease-causing organisms may be the earliest sign of disease. The increase in temperature activates the body mechanisms that are necessary to fight off foreign substances. Measuring the pulse rate is useful in determining the character of the heartbeat and of the circulatory system.

TESTS AS DIAGNOSTIC AIDS

In many cases, the final diagnosis of an animal disease is dependent upon a laboratory test. Some involve mea-

Table 5: Some Common Diseases of Dogs

name(s) of disease	causative agent	nature of disease
Distemper	virus	affects nonvaccinated (nonimmunized) puppies in contact with infected animals; symptoms include loss of appetite, fever; inflammation of the brain is usual cause of death; some dogs may recover, but others have spastic tremors; foxes, wolves, mink, skunks, raccoons, and ferrets also susceptible
Infectious hepatitis (Rubarth's disease)	virus	affects dogs by causing hemorrhages and severe liver damage; affects foxes by causing inflammation of the brain; clinical signs are variable because disease symptoms vary from severe to inapparent (*i.e.*, no manifest signs)
Salmon poisoning	rickettsia	occurs after consumption of raw salmon or trout carrying rickettsial-infected flatworm (fluke) larvae (*Nanophyetus salmincola*); affects dogs, foxes, and coyotes primarily in the Pacific northwestern United States; symptoms include high fever, swollen lymph nodes; usually fatal within five days
Prostatitis	varied	inflammation of a gland near the urinary bladder (prostate gland) in male dogs; usually controlled by antibiotic drugs; other prostate-gland disorders may result from tumours (carcinoma, sarcoma) or from abnormal increase in cell multiplication (hyperplasia)
Congenital heart disease	inherited tendency	may occur in 1 percent of all dogs; heart disorders may lead to secondary diseases such as pneumonia, accumulation of fluid in body cavities, laboured breathing, edema; heart failure occurs
Hip dysplasia	apparently inherited tendency	crippling disorder common in many breeds (especially German shepherds); a shallow hip socket (acetabulum) results in an unstable hip joint, particularly during motion of hindleg
Kidney stones (calculi, urolithiasis)	hereditary, functional disturbance	calculi develop in kidney, bladder, and male urethra (tube from bladder to outside of body); surgery usually necessary; inherited types include cystine calculi in certain dachshunds and uric acid calculi in male dalmatians
Hypothyroidism	functional disturbance	thyroid gland may function marginally or be absent; symptoms include awkward, slow movement, coarse, dry coat; treatment includes iodine, thyroid preparations
Dermatitis	varied	common symptoms include skin inflammation and loss of hair; causative agents include nutritional deficiencies, bacterial infections, hypothyroidism, allergies, hormone imbalances, and parasites (*e.g.*, fleas, lice, mites, fly larvae, and ticks)
Strychnine poisoning	chemical compound	accidental ingestion of 0.75 milligram of the poison (found in rat poisons) per kilogram (about 2¼ pounds) of body weight may cause death from convulsions and respiratory distress
Glaucoma	hereditary tendency in some breeds	a group of eye diseases in which the retina and optic nerve are damaged; certain breeds have a hereditary tendency for the disease; other breeds develop glaucoma as a result of other eye disorders
Granulomatous colitis	not yet characterized	usually found in boxer dogs; symptoms include bloody diarrhea; severely and chronically affected dogs become emaciated; an infectious agent observed microscopically in the thickened colon has not yet been isolated or characterized
Pancreatitis	unknown	in acute types the gland may be destroyed because of inflammation from unknown causes; an animal that lives may develop diabetes mellitus or be unable to secrete enzymes from pancreas, or both, thus preventing digestion, which increases the appetite and causes progressive weight loss; treatment difficult

suring the amount of certain chemical constituents of the blood or body fluids, determining the presence of toxins (poisons), or examining the urine and feces. Other tests are designed to identify the causative agents of the disease. The removal and examination of tissue or other material from the body (biopsy) is used to diagnose the nature of abnormalities such as tumours. Specific skin tests are used to confirm the diagnoses of various diseases—*e.g.*, tuberculosis and Johne's disease in cattle and glanders in horses (Table 3).

Confirmation of the presence in the blood of abnormal quantities of certain constituents aids in diagnosing certain diseases. Abnormal levels of protein in the blood are associated with some cancers of the bone, such as multiple myeloma in horses and dogs. Animals with diabetes mellitus have a high level of the carbohydrate glucose and the steroid cholesterol in the blood. The combination of an increase in the blood level of cholesterol and a decrease in the level of iodine bound to protein indicates hypothyroidism (underactive thyroid gland). A low level of calcium in the serum component of blood confirms milk fever in lactating dairy cattle. An increase in the activities of certain enzymes (biological catalysts) in the blood indicates liver damage. An increase in the blood level of the bile constituent bilirubin is used as a diagnostic test for hemolytic crisis, a disease in which red blood cells are rapidly destroyed by organisms such as *Babesia* species in dogs and in cattle and *Anaplasma* species in cattle.

Blood tests

The examination of the formed elements of blood, including the oxygen-carrying red blood cells (erythrocytes), the white blood cells (neutrophils, eosinophils, basophils, lymphocytes, and monocytes), and the platelets, which function in blood coagulation, is helpful in diagnosing certain diseases. Examination of the blood cells of cattle may reveal abnormal lymphocytic cells characteristic of leukemia. Low numbers of leucocytes indicate the presence of viral diseases, such as hog cholera and infectious hepatitis in dogs. Neutrophil levels increase in chronic bacterial diseases, such as canine pneumonia and uterine infections in female animals. Elevated monocyte levels occur in chronic granulomatous diseases; *e.g.*, histoplasmosis and tuberculosis. Canine parasitism and allergic skin disorders are characterized by elevated eosinophil levels. Prolonged clotting time may be associated with a deficiency of platelets.

Anemia has many causes. They include hemorrhages from blood loss after injuries; the destruction of red blood cells by the rickettsia *Haemobartonella felis* in cats; incompatible blood transfusions in dogs; the inadequate production of normal red blood cells, which occurs in iron or cobalt deficiency after exposure to radioactive substances; general malnutrition; and contact with substances that depress the activity of bone marrow.

Poisonings occur commonly in animals. Some species are more sensitive to certain poisons than others. Swine develop mercury poisoning if they eat too much grain that has been treated with mercury compounds to retard spoilage. Dogs may be poisoned by the arsenic found in pesticides or by strychnine, which is found in rat poison. Many plants are poisonous if eaten, such as bracken fern, which poisons cattle and horses, and ragwort, which contains a substance poisonous to the liver of cattle.

Examination of an animal's urine may reveal evidence of kidney diseases or diseases of the entire urinary system or a generalized systemic disease. The presence of protein in the urine of dogs indicates acute kidney disease (nephritis). Although constituents of bile normally are found in the urine of dogs, the quantity increases in dogs with the presence of infectious hepatitis, a disease of the liver. The presence of abnormal amounts of the simple carbohydrate glucose and of ketone bodies (organic compounds involved in metabolism) in an animal's urine is used to diagnose diabetes mellitus, a disease in which the pancreas cannot form adequate quantities of a substance (insulin) important in regulating carbohydrate metabolism. The urine of horses with azoturia (excessive quantities of nitrogen-containing compounds in the urine, Table 4) or muscle breakdown may contain a dark-coloured molecule called myoglobin.

The presence of eggs or parts of worms in the excrement of animals suspected of suffering from intestinal parasites, such as roundworms, tapeworms, or flatworms, aids in diagnosis. Feces that are light in colour, have a rancid odour, contain fat, and are poorly formed may indicate the existence of a chronic disease of the pancreas. Clay-coloured fatty feces suggest obstruction of the bile duct, which conveys bile to the intestine during digestion.

Identification of causative agents

The identification of a disease-causing microorganism within an animal enables the veterinarian to choose the best drug for therapy. Agglutination tests, which utilize serum samples of animals and microorganisms suspected of causing a disease, many times confirm the presence of the following bacterial diseases (Table 3): brucellosis in cattle and swine, salmonellosis in swine, leptospirosis in cattle, and actinobacillosis in swine and cattle. Other tests measure the antibodies (specific proteins formed in re-

Table 6: Some Common Diseases of Domestic Cats

name(s) of disease	causative agent	nature of disease
Feline distemper (panleukopenia, infectious enteritis)	virus	the most important viral disease of cats; wildcats and raccoons also susceptible; number of white blood cells decreases; fluid losses cause dehydration; treatment includes replacing fluid and preventing bacterial infections; vaccination advisable in kittens
Feline rhinotracheitis (pneumonitis, coryza, and influenza)	viruses (*e.g.*, *Miyagawanella*)	any upper-respiratory viral infection with eye and nose involvement; common among cats; seldom causes death; similar to severe head cold in man; treatment includes antibiotic drugs
Feline picornavirus pneumonia	virus	symptoms include watery eyes, nasal inflammation; pneumonia; in severe cases, death is preceded by laboured breathing
Lymphocytic leukemia	virus	cancerous lymphocytic cells enter blood from a malignant tumour (lymphosarcoma); lymph nodes may become enlarged; a progressive anemia, an increase in the level of circulating immature lymphocytes, symptoms may precede death; no curative treatment known thus far
Urinary-bladder infection with stones and obstruction (cystitis)	unknown	urethra is obstructed with crystals of magnesium ammonium phosphate and mucus associated with infection of the urinary bladder (cystitis); death occurs if obstruction not relieved; exact cause of syndrome (set of symptoms) unknown but may be related to diet or to a virus
Ringworm (dermatomycosis)	fungus (*Microsporum canis; Trichophyton* species)	kittens most often affected; disease (a scaly, spreading skin condition) may be transmitted to children; some cats may carry the disease and show no clinical signs
Toxoplasmosis	protozoan (*Toxoplasma gondii*)	toxoplasmosis probably occurs frequently in cats; chronic forms affect abdominal organs; organisms may invade nearly any body tissue
Ear mites, ear inflammation (otitis externa)	mite (*Otodectes cynotis*)	acquired through contact of kitten with an infected mother; constant scratching of ears eventually causes raw sores and scabs; treatment includes killing the mites and controlling secondary bacterial infections
Osteodystrophy fibrosa (osteogenesis imperfecta)	nutritional deficiencies	once considered congenital in kittens but probably is nutritional, resulting from a calcium deficiency; lameness, first noted at ten to 15 weeks, may lead to paralysis of rear legs, slow growth, bone fractures, and severe pain; treatment includes a diet with adequate calcium
"Fur ball" disease	physical agent	hair balls accumulate in stomach as a result of constant grooming; surgical removal sometimes necessary

Table 7: Some Common Diseases of Domestic Poultry

name(s) of disease	causative agent	nature of disease
Coccidiosis	protozoans (*e.g., Emieria tenella*)	affected birds show low egg production, poor growth rates, and high mortality; cecal coccidiosis (the cecum is a pouch in the large intestine), a serious disease caused by tenella; many protozoa produce intestinal symptoms
Blackhead (histomoniasis)	protozoan (*Histomonas meleagridis*)	may kill up to 50 percent of a turkey flock; symptoms include droopy wings and damage to liver and cecum; *Heterakis gallinae*, a worm in the turkey cecum, probably transmits the protozoan
Psittacosis (ornithosis)	virus (*Bedsonia*)	affects parakeets, canaries, parrots, pigeons, and other pet birds; symptoms include lack of appetite, ruffled feathers; can be transmitted to man
Avian lymphomatosis	virus	an infectious disease; manifestations include formation of tumours; three forms occur, depending on location of tumours: visceral (internal organs); neural (nerve); and ocular (eye) lymphomatosis
Pullorum disease	bacterium (*Salmonella pullorum*)	affects most species of fowl (chickens); mortality rate high, also reduces egg productivity of mature females; transmitted from egg-producing organs of hen to chick; disease causes hemorrhages throughout body
Digestive diseases in caged birds	functional disturbance	symptoms include slowly emptying, loosely hanging crop (digestive organ); deficiency of grit (particles that aid in digestion) results in poor nutrition; symptoms include obstruction of crop, vomiting, intestinal inflammation, and various liver disorders
Fractured legs in caged birds	physical agent	in canaries, about 70 percent of fractures involve the metatarsus (hindfoot); in budgerigars, 70 percent involve the tibia (hindleg)

sponse to a foreign substance in the body) formed against a disease-causing agent, such as those that cause brucellosis, foot-and-mouth disease, infectious hepatitis in dogs, and fowl pest.

The modern veterinary diagnostic laboratory performs, in addition to the tests mentioned, tests of cells in the bone marrow; specific-organ-function tests (liver, kidney, pancreas, thyroid, adrenal, and pituitary glands); radioisotope tests, tissue biopsies, and histochemical analyses; and tests concerning blood coagulation and body fluids.

Survey of animal diseases

INFECTIOUS AND NONINFECTIOUS DISEASES

Diseases may be either infectious or noninfectious. The term infection, as observed earlier, implies an interaction between two living organisms, called the host and the parasite. Infection is a type of parasitism, which may be defined as the state of existence of one organism (the parasite) at the expense of another (the host). Agents (*e.g.*, certain viruses, bacteria, fungi, protozoans, worms, and arthropods) capable of producing disease are pathogens. The term pathogenicity refers to the ability of a parasite to enter a host and produce disease; the degree of pathogenicity—that is, the ability of an organism to cause infection—is known as virulence. The capacity of a virulent organism to cause infection is influenced both by the characteristics of the organism and by the ability of the host to repel the invasion and to prevent injury. A pathogen may be virulent for one host but not for another. Pneumococcal bacteria, for example, have a low virulence for mice and are not found in them in nature; if introduced experimentally into a mouse, however, the bacteria overwhelm its body defenses and cause death.

Many pathogens (*e.g.*, the bacterium that causes anthrax, Table 3) are able to live outside the animal's body until conditions occur that are favourable for entering and infecting it. Pathogens enter the body in various ways—by penetrating the skin or an eye, by being eaten with food, or by being breathed into the lungs. After their entry into a host, pathogens actively multiply and produce disease by interfering with the functions of specific organs or tissues of the host. Table 3 lists some infectious and parasitic diseases of animals and the causative agents.

Before a disease becomes established in a host, the barrier known as immunity must be overcome. Defense against infection is provided by a number of chemical and mechanical barriers, such as the skin, mucous membranes and secretions, and components of the blood and other body fluids. Antibodies, which are proteins formed in response to a specific substance (called an antigen) recognized by the body as foreign, are another important factor in preventing infection. Immunity among animals varies with species, general health, heredity, environment, and previous contact with a specific pathogen.

As certain bacterial species multiply, they may produce and liberate poisons, called exotoxins, into the tissues; other bacterial pathogens contain toxins, called endotoxins, which produce disease only when liberated at the time of death of the bacterial cell. Some bacteria, such as certain species of *Clostridium* and *Bacillus*, have inactive forms called spores, which may remain viable (*i.e.*, capable of

Table 8: Some Common Diseases of Fish

name(s) of disease	causative agent	nature of disease
Mouth fungus (cotton-wool disease)	bacterium (*Chondrococcus columnaris*)	fungus-like disease inaccurately named, since causative agent is a bacterium; a contagious disease; produces swollen lips, loss of appetite, and a "cotton-wool-like" growth on mouth; treatment utilizes antibiotic drugs
Tailrot	bacteria (*Haemophilus* and *Aeromonas* species)	infection may spread from fin and tail to body and cause death; disease may be controlled by surgery or use of drugs
Dropsy (ascites)	possibly associated with a bacterium (*Aeromonas punctata*)	characterized by accumulation of liquid in internal organs and tissues, inflammation of intestines, and infection of liver; epidemics can occur; most treatment except the antibiotic chloramphenicol unreliable
Red pest of eels	bacteria (*Vibrio anguillarum; Aeromonas* species)	*Vibrio* multiplies readily in salty water (1.5 to 3.5 percent) and can cause extensive blood-coloured areas on skin; *Aeromonas* species produce ulcers in the skin
Fish tuberculosis	bacteria (*Mycobacterium* species)	symptoms include loss of appetite, emaciation (leanness), skin defects, blood spots, ulcers, and cysts (on internal organs)
Eye fungus	fungus	infection follows damage to cornea of eye; a typical symptom is a white cotton-wool growth hanging from eye; untreated eye is destroyed within days; untreated fish die
Fish lice	louse (*Argulus* species)	bloodsucking parasites on the surfaces of many fish species
Skin flatworms (flukes)	platyhelminth	small parasites; cause skin colour to fade, blood spots, increased respiratory rate, and debilitation
Bursting of the swim bladder	physical agent	occurs if fish in deep water rise to surface too rapidly; fatal
Air embolism	physical agent	occurs if oxygen content of water is higher than normal, as when water temperature is higher than normal; bubbles of nitrogen gas in blood cause the disease

developing into active organisms) for many years; spores are highly resistant to environmental conditions such as heat, cold, and chemical compounds called disinfectants, which are able to kill many active bacteria.

The term infestation indicates that animals, including spiny-headed worms (Acanthocephala), roundworms (Nematoda), flatworms (Platyhelminthes), and arthropods such as lice, fleas, mites, and ticks, are present in or on the body of a host. An infestation is not necessarily parasitic. Table 3 includes various infestations.

Non-infectious diseases

Noninfectious diseases are not caused by virulent pathogens and are not communicable from one animal to another (see Table 4). They may be caused by hereditary factors or by the environment in which an animal lives. Many metabolic diseases are caused by an unsuitable alteration, sometimes brought about by man, in an animal's genetic constitution or in its environment. Metabolic diseases usually result from a disturbance in the normal balance of the physiological mechanisms that maintain stability, or homeostasis. Examples of metabolic diseases include overproduction or underproduction of hormones, which control specific body processes; nutritional deficiencies; poisoning from such agents as insecticides, fungicides, herbicides, fluorine, and poisonous plants; and inherited deficiencies in the ability to synthesize active forms of specific enzymes, which are the proteins that control the rates of chemical reactions in the body.

Excessive inbreeding (*i.e.*, the mating of related animals) among all domesticated animal species has resulted in an increase in the number of metabolic diseases and an increase in the susceptibility of certain animals to infectious diseases.

ZOONOSES

As stated previously, zoonoses are human diseases acquired from or transmitted to any other vertebrate animal. Zoonotic diseases are common in currently developing countries throughout the world and constitute, with starvation, the major threat to human health. More than 150 such diseases are known; some examples are listed in Table 10.

Types of zoonoses

Zoonoses may be separated into four principal types, depending on the mechanisms of transmission and epidemiology. One type includes the direct zoonoses, such as rabies and brucellosis, which are maintained in nature by one vertebrate species. The transmission cycle of the cyclozoonoses, of which tapeworm infections are an example, requires at least two different vertebrate species. Both vertebrate and invertebrate animals are required as intermediate hosts in the transmission to humans of metazoonoses; arboviral and trypanosomal diseases are good examples of metazoonoses. The cycles of saprozoonoses (for example, histoplasmosis) may require, in addition to vertebrate hosts, specific environmental locations or reservoirs.

Most animals that serve as reservoirs for zoonoses are domesticated and wild animals with which man commonly associates. People in occupations such as veterinary medicine and public health, therefore, have a greater

Table 9: Some Important Diseases of Some Common Laboratory Animals

name or type of disease	causative organism
Mice	
Bacterial diseases	
Mouse pneumonitis	*Miyagawanella bronchopneumoniae*
Eperythrozoonosis	*Eperythrozoon coccoides*
Mycoplasma infection	*Mycoplasma* species
Pus-producing lesions	*Pseudomonas aeruginosa*
Salmonellosis	*Salmonella*
Pseudotuberculosis	*Pasteurella pseudotuberculosis*
Rat-bite fever	*Streptobacillus moniliformis*
Fungal disease	
Dermatophytoses (ringworm)	*Trichophyton* species
Viral diseases	
Mouse pox (ectromelia)	Ectromelia virus
Poliomyelitis of mice (Theiler's disease)	Theiler's encephalomyelitis virus
EDIM (epizootic diarrhea of infant mice)	EDIM virus
LIVIM (lethal intestinal virus of infant mice)	LIVIM virus
Protozoal diseases	
Coccidiosis	*Eimeria falciformis*
Toxoplasmosis	*Toxoplasma gondii*
Nosematosis (encephalitozoonosis)	*Nosema cuniculi*
Helminthic diseases	
Mouse tapeworm	*Hymenolepsis nana*
Rat tapeworm	*Hymenolepsis diminuta*
Cat tapeworm	*Taenia taeniaeformis*
Mouse pinworm	*Aspicularis tetraptera*
Pinworm	*Syphacia obvelata*
Liver threadworm	*Capillaria hepatica*
Arthropod diseases	
Sucking louse	*Polyplax serratus*
Mite	*Psorergates simplex*
Rats	
Bacterial and fungal diseases	
Mycoplasma infection (associated with chronic pneumonia)	*Mycoplasma* species
Salmonellosis	*Salmonella* species
Infectious anemia	*Haemobartonella muris*
Pus-forming lesions	*Pseudomonas aeruginosa* *Pasteurella pneumotropica*
Rat-bite fever	*Streptobacillus moniliformis* *Diplococcus pneumoniae*
Leptospirosis (Weil's disease)	*Leptospira* species
	Corynebacterium kutscheri
Dermatophytoses (ringworm; fungus)	*Trichophyton*
Viral diseases	
Pneumonitis	rat virus (Kilham)
Salivary-gland disease	rabula virus
Hemorrhagic encephalitis	hemorrhagic encephalopathy virus (HER)

name or type of disease	causative organism
Rats (cont.)	
Protozoal diseases	
Coccidiosis	*Eimeria nieschulzi* *Hepatozoon muris*
Toxoplasmosis	*Toxoplasma gondii*
Nosematosis (encephalitozoonosis)	*Nosema cuniculi*
Helminthic diseases	
Mouse tapeworm	*Hymenolepsis nana*
Rat tapeworm	*Hymenolepsis diminuta*
Cat tapeworm	*Taenia taeniaeformis*
Bladder threadworm	*Trichosomoides crassicauda*
Cecal worm	*Heterakis spumosa*
Liver threadworm	*Capillaria hepatica*
Arthropod diseases	
Sucking louse	*Polyplax spinulosa*
Ear mite	*Notoedres notoedres*
Hair mite	*Radifordia ensifera*
Guinea pigs	
Bacterial and fungal diseases	
Streptococcal infections (cervical abscesses and lymphadenitis)	*Streptococcus* species
Salmonellosis	*Salmonella* species
Bronchopneumonia	*Bordatella bronchiseptica*
Respiratory infections	*Klebsiella* species
Dermatophytoses (ringworm, fungus)	*Trichophyton* species
Viral diseases	
Cytomegalic inclusion disease	salivary-gland virus
Lymphocytic choriomeningitis	LCM virus
Protozoal diseases	
Coccidiosis	*Eimeria caviae*
Toxoplasmosis	*Toxoplasma gondii*
Hamsters	
Cytomegalic inclusion disease	salivary-gland virus
Encephalomyocarditis	picorna virus
Wet tail (regional ileitis)	virus, bacterium
Salmonellosis	*Salmonella* (bacterium)
Mouse tapeworm	*Hymenolepsis nana* (helminth)
Rabbits	
Pasteurellosis (snuffles)	*Pasteurella* (bacterium)
Spirochetosis (vent disease)	*Spirochaeta* (bacterium)
Mucoid enteritis	bacterium
Myxomatosis	myxoma virus
Rabbit pox	virus
Coccidiosis	*Eimeria* species (protozoan)
Ear mites	*Notoedres notoedres*
Nosematosis	*Nosema cuniculi*

Table 10: A Partial List of Zoonoses

disease	causative organism	animals principally involved
Viral diseases		
Arbovirus infections		rodents, birds, equines, goats, sheep, monkeys, swine, marsupials
Febrile illnesses	various arboviruses	
Hemorrhagic fever		
Epidemic nephroso-nephritis		
Encephalitis (mosquito-borne and tick-borne)		
Encephalomyocarditis	encephalomyocarditis virus	rodents
Herpes B virus disease	herpes B virus	monkeys
Herpes T (= M) virus infection	herpes T (= M) virus	monkeys
Influenza	influenza virus type A	swine
Lymphocytic choriomeningitis	lymphocytic choriomeningitis virus	mice, dogs, monkeys
Newcastle disease	Newcastle disease virus	chickens
Poxvirus infections		
Buffalopox	buffalopox virus	buffalo
Camelpox	camelpox virus	camels
Cowpox	cowpox or vaccinia virus	cattle
Orf (contagious ecthyma)	contagious ecthyma virus	sheep and goats
Paravaccinia (milkers' nodules)	paravaccinia virus	cattle
Yaba disease	yaba virus	monkeys
Rabies	rabies virus	carnivores, bats, and other wild animals
Sendai virus disease	sendai virus	swine, rodents
Cat-scratch disease	cat-scratch virus	cats
Rickettsial diseases		
Flea-borne		
Murine (endemic typhus)	*Rickettsia mooseri*	rats, mice
Mite-borne		
Rickettsial pox	*R. akari*	mice
Scrub typhus (tsutsugamushi)	*R. tsutsugamushi*	rodents
Tick-borne		
(North) Queensland tick typhus	*R. australis*	bandicoots, rodents
Spotted fever (including Rocky Mountain, Brazilian, and Colombian spotted fevers)	*R. rickettsii*	dogs, rodents, and other animals
Fièvre boutonneuse	*R. conorii*	dogs, rodents
Kenya typhus		
South African tick typhus		
Indian tick typhus		
North Asian tick-borne rickettsiosis	*R. sibericus*	rodents
Rickettsial diseases (cont.)		
Q fever	*Coxiella burnetii*	cattle, sheep, goats, and other domesticated and wild mammals, birds
Bedsonia infection		
Psittacosis (ornithosis)	Psittacosis (P.L.T.) group (*Bedsonia*)	psittacines and other birds
Bacterial diseases		
Anthrax	*Bacillus anthracis*	ruminants, equines, swine
Brucellosis	*Brucella abortus, B. suis, B. melitensis*	cattle, swine, goats, sheep, horses
Enterobacterial infections		
Arizona infections	*Arizona* species	poultry, swine, dogs
Colibacillosis	*E. coli*	poultry, swine, dogs
Salmonellosis	*Salmonella* species	mammals and birds
Erysipeloid	*Erysipelothrix rhusiopathiae*	swine, poultry, fish
Glanders	*Actinobacillus mallei*	equines
Leptospirosis	*Leptospira interrogans*	rodents, dogs, swine, cattle, bandicoots
Listeriosis	*Listeria monocytogenes*	rodents, sheep, cattle, swine
Melioidosis	*Pseudomonas pseudomallei*	rodents, sheep, cattle, swine
Pasteurellosis	*Pasteurella multocida, P. haemolytica*	mammals, birds
Plague	*Pasteurella pestis*	rodents
Pseudotuberculosis	*Pasteurella pseudotuberculosis*	rodents, cats, fowls
Rat-bite fever	*Spirillum minus, Streptobacillus moniliformis*	rodents
Relapsing fever (tick-borne)	*Borrelia* species	rodents
Staphylococcosis	*Staphylococcus aureus*	cattle, dogs, occasionally other animals
Streptococcosis	*Streptococcus* species	mammals
Tuberculosis	*Mycobacterium tuberculosis var. hominis*	dogs, swine, monkeys
	M. bovis	cattle, goats, swine, cats
	M. avium	poultry, swine, cattle
Tularaemia	*Pasteurella tularensis*	rabbits, hares, sheep, wild rodents
Vibriosis	*Vibrio fetus; V. parahaemolyticus*	cattle, sheep fish
Fungal disease		
Dermatophytosis		
Ringworm, favus	*Microsporum* species	cats, dogs, horses
	Trichophyton species	horses, cattle, poultry, small mammals

exposure to zoonoses than do those in occupations less closely concerned with animals.

In addition to the numerous human diseases spread by contact with the parasitic worm helminth and by contact with arthropods (see Table 10), many diseases are transmitted by the bites and venom of certain animals; poisonous or diseased food animals also transmit diseases. Dog bites may seriously injure tissues and also can transmit bacterial infections and rabies, a disease of viral origin. The bite of a diseased rat may transmit any of several diseases to man, including plague, salmonellosis, leptospirosis, and rat-bite fevers. Cat-scratch disease may be transmitted through cat bites, and the deadly herpes B virus can spread by monkey bites. The bites of venomous snakes and fish account for considerable human discomfort and death. About 200 of the 2,500 known species of snakes can cause human disease. One estimate for snakebite deaths worldwide is 30,000 to 40,000 per year, the vast majority of them in Asia. Poisonous wild animals inadvertently used for food include animals harbouring the anthrax bacillus and those containing the causative agents of salmonellosis, trichinosis, and fish-tapeworm infection. The flesh of various types of fish is toxic to man. Japanese puffers, for example, contain the poisonous chemical compound tetrodotoxin; scombroid fish harbour *Proteus morganii,* which causes gastrointestinal diseases; and mullet and surmullet can cause nervous disturbances.

Control of zoonoses

Approaches to the control of zoonoses differ according to the type under consideration. Because the majority of direct zoonoses and cyclozoonoses and some saprozoonoses are most effectively controlled by techniques involving the animal host, methods used to combat these diseases are almost entirely the responsibility of veterinary medicine. A good example is the elimination of stray dogs, for they are an important factor in the control of zoonoses such as rabies, hydatid disease, and visceral larva migrans. In addition, the control of diseases such as brucellosis and tuberculosis in cattle involves a combination of methods—mass immunization, diagnosis, slaughter of infected animals, environmental disinfection, and quarantine. Several supportive measures for the control of disease are useful in some cases. Air-sanitation measures are helpful in direct zoonoses in which human illness is spread by droplets or dust, and zoonotic infections that are spread through a fluid medium, such as water or milk, sometimes can be controlled. Heat, cold, and irradiation are effective in killing the immature forms of *Trichinella spiralis,* the causative agent of trichinosis, in meat; and certain antibiotic drugs help to prevent deterioration of food.

The control of metazoonoses may be directed at the infected vertebrate hosts, at the infected invertebrate host, or at both. Particularly effective in this instance has been the use of chemical insecticides to attack the invertebrate carriers of specific infections, even though several difficulties have been encountered—for example, the inaccessibility of the invertebrate to the chemicals, which occurs with organisms that breed in swiftly flowing waters or in dense vegetation, and the development of insecticide re-

Table 10: A Partial List of Zoonoses (continued)

disease	causative organism	animals principally involved
Protozoal diseases		
Amebiasis	*Entamoeba histolytica*	dogs, lower primates
Balantidiasis	*Balantidium coli*	swine
Coccidiosis	*Isospora* species	dogs
Leishmaniasis		
Kala Azar	*Leishmania donovani*	dogs
Oriental sore	*Leishmania tropica*	dogs, rodents
American	*Leishmania* species	dogs, wild mammals
Malaria	*Plasmodium knowlesi*	monkeys
	Plasmodium simium	monkeys
	Plasmodium cynomolgi	monkeys
Pneumocystis infection	*Pneumocystis carinii*	dogs
Toxoplasmosis	*Toxoplasma gondii*	mammals, birds
Trypanosomiasis	*Trypanosoma cruzi*	dogs, small mammals
	Trypanosoma rangeli	
	Trypanosoma rhodesiense	antelope, cattle
Platyhelminthic diseases		
Trematode (fluke) diseases		
Amphistomiasis	*Gastrodiscoides hominis*	swine
Cercarial dermatitis	*Schistosoma* species	birds, mammals
Clonorchiasis	*Clonorchis sinensis*	dogs, cats, swine, wild mammals, fish
Dicrocoeliasis	*Dicrocoelium* species	ruminants
Echinostomiasis	*Echinostoma ilocanum*	cats, dogs, rodents
	Echinostoma species	
Fascioliasis	*Fasciola hepatica, F. gigantica*	ruminants
Fasciolopsiasis	*Fasciolopsis buski*	swine, dogs
Heterophyiasis	*Heterophyes heterophyes* (and other heterophids)	cats, dogs, fish
Metagonimiasis	*Metagonimus yokogawai*	cats, dogs, fish
Opisthorchiasis	*Opisthorchis felineus*	cats, dogs
	Opisthorchis viverrini, other species	wildlife, fish
Paragonimiasis	*Paragonimus westermani*, other species	cats, dogs, wildlife
Schistosomiasis	*Schistosoma japonicum*	wild and domestic mammals
	S. mansoni	baboons, rodents
	S. mattheei, occasionally other species	cattle, sheep, antelopes
Cestode (tapeworm) diseases		
Bertiella infection	*Bertiella studeri*	primates
Diphyllobothriasis	*Diphyllobothrium latum*	fish, carnivores
Dipylidiasis	*Dipylidium caninum*	dogs, cats
Echinococcosis	*Echinococcus granulosus*	dogs, wild carnivores, domestic and wild ungulates
	E. multilocularis	foxes, dogs, rodents
Hymenolepiasis	*Hymenolepis diminuta, H. nana*	rats, mice
Inermicapsifer infection	*Inermicapsifer madagascarensis*	rodents
Platyhelminthic diseases (cont.)		
Sparganosis	Pseudophyllidea tapeworms	mice, carnivores including cats, and other vertebrates
Taeniasis, cysticercosis, and coenuriasis	*Taenia saginata*	cattle
	Taenia solium	swine
	Multiceps multiceps	sheep, dogs
Nematode diseases		
Ancylostomiasis	*Ancylostoma ceylanicum*, other species	dogs
Ascariasis	*Ascaris suum*	swine
Capillariasis	*Capillaria hepatica*	rodents
Dracuncoliasis	*Dracunculus medinensis*	dogs, other carnivores
Filariasis	*Brugia malayi*	primates, other mammals
	Dirofilaria species, occasionally other species	cats, dogs, other mammals
Larva migrans	*Ancylostoma braziliense*, other species	cats, dogs
	Anglostrongylus cantonensis	rats
	Anisakis species	fish
	Gnathostoma spinigerum	cats, dogs, other vertebrates
	Toxocara canis, other ascarid species	dogs, other vertebrates
Oesophagostomiasis	*Oesophagostomum apiostomum*	primates
Strongyloidiasis	*Strongyloides stercoralis*, occasionally other species	dogs, primates
Ternidens infection	*Ternidens deminutus*	primates
Trichinosis	*Trichinella spiralis*	swine, rodents, wild carnivores, marine mammals
Trichostrongylosis	*Trichostrongylus colubriformis*, occasionally other species	ruminants
Arthropod diseases		
Acariasis	*Sarcoptes* species	domesticated animals
Tunga infections	*Tunga penetrans*	domesticated and wild mammals
Myiasis	*Cochliomyia, Cordylobia, Dermatobia, Gastrophilus, Hypoderma, Oestrus*, and other genera	mammals
Pentastomid infections (including Halzoun)	*Linguatula* species, *Armillifer* species, *Porocephalus* species	dogs, snakes, and other vertebrates

sistance by the organisms. Insecticides are used to destroy the mosquitoes that spread malaria (*Anopheles*). Mechanical filters placed across irrigation ditches help to prevent the dissemination of the snails that transmit *Schistosoma mansoni,* a parasitic flatworm.

DISEASE PREVENTION, CONTROL, AND ERADICATION

Prevention is the first line of defense against disease. At least four preventive techniques are available for use in the prevention of disease in an animal population. One is the exclusion of causative agents of disease from specific geographic areas, or quarantine. A second preventive tool utilizes control methods such as immunization, environmental control, and chemical agents to protect specific animal populations from endemic diseases, diseases normally present in an area. The third preventive measure concerns the mass education of people about disease prevention. Finally, early diagnosis of illness among members of an animal population is important so that disease manifestations do not become too severe and so that affected animals can be more easily managed and treated.

Quarantine—the restriction of movement of animals suffering from or exposed to infections such as bluetongue and scrapie (in sheep), foot-and-mouth disease (in cattle), and rabies (in dogs)—is one of the oldest tools of preventive medicine. It was applied to domesticated animals as early as Roman times. The establishment of international livestock quarantine in the United States in 1890 provided for the holding of all imported cattle, sheep, and swine at the port of entry for 90, 15, and 15 days, respectively. In this way, such diseases as Nairobi sheep disease, surra, and infections caused by *Brucella melitensis* were eliminated or excluded from the United States, but international quarantine barriers did not prevent the entry of bluetongue, scrapie, and the tick *Rhipicephalus evertsi,* which is a carrier for several animal diseases. On the other hand, long-term quarantine of all dogs entering Great Britain has been effective since its initiation in 1919 (the quarantine also includes cats). It is possible that aircraft may pose new problems regarding livestock-disease quarantine since many disease carriers (*e.g.,* insects and viruses) may be accidentally brought by plane into a country.

Contact through travel

Mass immunization as a preventive technique has the advantage of allowing the resistant animal freedom of movement, unlike environmental control, in which the animal is confined to the controlled area; immunization may, however, provide only short-lived and partial protection. Mass-inoculation techniques against diseases such as Newcastle disease in chickens and distemper in mink and dogs have been successful. Animal diseases have been prevented by methods involving environmental control, including the maintenance of safe water supplies, the hygienic disposal of animal excrement, air sanitation, pest control, and the improvement of animal housing. One specific environmental program, called the portable-calf-pen system, involves routine movement of the pens to avoid a concentration of specific pathogens in them. Other programs involve the utilization of automatic and sani-

Table 11: Animal Diseases Usually Confined to Certain Regions of the World

name(s) of disease	animal(s) affected	causative organism	distribution	nature of disease
African horse sickness (AHS), equine plague, pestis equorum, perdesiekte	primarily horses, donkeys, mules (occasionally zebras and dogs)	AHS virus	primarily Africa and Middle East; occasionally India, Pakistan	a seasonal disease occurring in late summer; acute form, sometimes fatal within five days, involves excessive fluid in lungs; symptoms of other forms include accumulation of fluid in body cavities
African swine fever (ASF), warthog disease, Montgomery's disease	swine	ASF virus	primarily Kenya and South Africa; occasionally Europe	highly contagious; usually fatal; resembles hog cholera in clinical manifestations (high fever, weakness in hindlegs, and hemorrhages throughout body) but can be distinguished by laboratory tests and isolation of the virus
Contagious pleuropneumonia, lung plague	cattle, buffalo, yaks, sheep, goats	*Mycoplasma mycoides*	Africa, Australia, Asia, Europe	transmitted by direct animal contact or by contaminated objects; an acute disease producing pneumonia and inflammation of the lung lining; vaccines ineffective because different strains of the organism occur throughout the world
East coast fever, theileriasis, Rhodesian red water or tick fever	cattle, African and Indian water buffalo	protozoan (*Theileria parva*)	Central Africa; East Africa	usually fatal; transmitted by three ticks containing pathogen; symptoms include high fever, swelling of lymph glands; not yet prevented effectively by vaccination
Foot-and-mouth disease (FMD), aphthous fever, aftosa	cattle, swine, sheep, goats	FMD virus	worldwide except North America, Central America, New Zealand	symptoms include high fevers, drool from mouth, where vesicles and ulcers form, and lameness; causes great economic losses throughout world; effective vaccines available
Fowl plague, fowl pest	birds, including chickens and turkeys	fowl-plague virus	Europe, Middle and Far East, Argentina, Japan	may cause no apparent symptoms; apparent symptoms include lack of appetite, swollen head, laboured breathing, and hemorrhaging
Heartwater, drunk bull sickness	cattle, sheep, goats	rickettsia (*Cowdria ruminantium*)	Africa (southern half); Madagascar	disease has acute and mild forms; symptoms include water in the membrane around heart and in the lung cavity, hemorrhages, and twitching
Louping ill (LI), infectious encephalomyelitis in sheep, trembling ill	primarily sheep (also cattle and man)	LI virus	British Isles, Czechoslovakia, U.S.S.R.	transmitted by bite of sheep tick; characterized by fever, dullness followed by excitement, muscular spasms, leaping gait, convulsions, and death
Nagana, tsetse disease, trypanosomiasis	most domesticated animals	protozoan (*Trypanosoma* species)	Africa	may be acute or inapparent; symptoms may include anemia resulting from red-blood-cell destruction; pathogen transmitted by tsetse fly (over 20 species of *Glossina*); prevents effective cattle production in nearly all of West Africa
Rift Valley fever (RVF), infectious enzootic hepatitis	cattle, sheep (occasionally man)	RVF virus	Central and South Africa	spread by bloodsucking insects associated with wild animals; symptoms include abdominal pain resulting from liver damage; young animals usually die; mature ones may recover
Rinderpest, cattle plague	cattle, sheep, goats, wild ruminants; yaks, caribou, gazelles, deer	rinderpest virus	primarily Asia, Africa, Philippines; rarely Europe	rapidly fatal; symptoms include fluid losses (dehydration) from diarrhea caused by massive pathological changes (*e.g.*, hemorrhages, ulcers) in intestinal tract
Surra	primarily in camels and horses; many animals susceptible	protozoan (*Trypanosoma evansi*)	primarily Far East (*e.g.*, China), India, Near East (*e.g.*, Iran); North Africa	transmitted by bloodsucking flies and mosquitoes; symptoms include anemia, loss of weight, large swellings in limbs, abdomen, and sex organs
Teschen disease, swine encephalomyelitis, porcine poliomyelitis	swine	Teschen virus	primarily Europe	symptoms include prostration, immobilization, nervous tremors, convulsions, paralysis of legs

tary watering and feeding equipment and buildings with environmental controls. The use of chemical compounds to prevent illness (chemoprophylaxis) includes a variety of pesticides, which are used to kill insects that transmit diseases, and substances either used internally or applied to the animal's body to prevent the transmission or the development of a disease. An example is the use of sulfonamide drugs in the drinking water of poultry to prevent coccidiosis (see Table 7). Environmental-control methods in the poultry industry have resulted in the most efficient means of poultry production developed thus far.

The early detection of a disease in a population of animals—a herd of cattle, for example—is particularly useful in controlling certain chronic infectious diseases, such as mastitis, brucellosis, and tuberculosis, as well as certain noninfectious diseases such as bloat. Laboratory tests—the agglutination test in pullorum disease, the tuberculin skin test for tuberculosis, the examination of feces for eggs of specific parasites, the physical and chemical tests performed on milk to diagnose bovine mastitis—are used for the early detection of diseases in an animal population.

Methods of disease control and eradication have been successful in various countries. In the United States, for example, the test-and-slaughter technique, in which simple tests are used to confirm the existence of diseased animals that are then slaughtered, has been of great value in controlling infectious and hereditary diseases, including dourine, a venereal disease in horses, fowl plague, and foot-and-mouth disease in cattle and deer. Bovine tuberculosis has been eliminated from Denmark, Finland, and The Netherlands and reduced to a low level in various other countries, including Great Britain, Japan, the United States, and Canada, by the test-and-slaughter method. Many infectious diseases have been eradicated from Great Britain—sheep pox, rinderpest, pleuropneumonia, glanders, and rabies. Diseases eliminated from Australia by a combination of methods—control of agents that carry disease, the test-and-slaughter technique, the use of chemical agents, and, more recently, biological control—include hog cholera, rinderpest, scrapie, glanders, surra, rabies, and foot-and-mouth disease.

In biological control, enemies of the agents that transmit the disease, enemies of the reservoir host, or a specific parasite are introduced into the environment. If a natural enemy of the tsetse fly could be found, for example, African sleeping sickness in man and trypanosomiasis in cattle could be controlled in West Africa. Successful biological control of the European-rabbit population in Australia has been accomplished through the use of the myxomatosis virus, which is transmitted by mosquitoes and causes the

formation of malignant tumours. Although the Brazilian white rabbit is relatively unaffected by the virus, it causes rapid death in the European rabbit. The elimination of the European rabbit in France by the virus was accompanied by a decrease in tick-borne typhus in people, suggesting that the rabbit may be a significant intermediate host for the causative agent, *Rickettsia conorii*. Screwworms, an immature form of the fly *Cochliomyia hominivorax*, have been eradicated in the United States by the release of more than 3,000,000,000 sterilized males.

Disease control and elimination programs require many sophisticated techniques, in addition to diagnosis and the slaughter of affected animals. They include: the control of insects known to transmit diseases; the cooperation of animal owners; the development through research of new diagnostic tests for use on large populations; the eradication of animal species from areas in which they are known to transmit disease; sterilization of strains of animals known to carry inheritable metabolic diseases; and effective meat inspection. (C.E.Co./Ed.)

DISEASES OF PLANTS

All species of plants, wild and cultivated alike, are subject to disease. Although each species is susceptible to characteristic diseases, these are, in each case, relatively few in number. The occurrence and prevalence of plant diseases vary from season to season, depending on the presence of the pathogen, environmental conditions, and the crops and varieties grown. Some plant varieties are particularly subject to outbreaks of diseases; others are more resistant to them.

General considerations

NATURE AND IMPORTANCE OF PLANT DISEASES

Plant diseases are known from times preceding the earliest writings. Fossil evidence indicates that plants were affected by disease 250 million years ago. The Bible and other early writings mention diseases, such as rusts, mildews, blights, and blast, that have caused famine and other drastic changes in the economy of nations since the dawn of recorded history. Other plant disease outbreaks with similar far-reaching effects in more recent times include late blight of potato in Ireland (1845–60); powdery and downy mildews of grape in France (1851 and 1878); coffee rust in Ceylon (starting in the 1870s); *Fusarium* wilts of cotton and flax; southern bacterial wilt of tobacco (early 1900s); Sigatoka leaf spot and Panama disease of banana in Central America (1900–65); black stem rust of wheat (1916, 1935, 1953–54); and southern corn leaf blight (1970) in the United States.

Economic impact of plant diseases

Loss of crops from plant diseases may result in hunger and starvation, especially in less developed countries where access to disease-control methods is limited and annual losses of 30 to 50 percent are common for major crops. In some years, losses are much greater, producing catastrophic results for those who depend on the crop for food. Major disease outbreaks among food crops have led to famines and mass migrations throughout history. The devastating outbreak of late blight of potato (*Phytophthora infestans*) that began in Europe in 1845 and brought about the Irish famine caused starvation, death, and mass migration of the Irish population. Of a population of eight million, approximately one million (about 12.5 percent) died of starvation and 1.5 million (almost 19 percent) emigrated, mostly to the United States, as refugees from the destructive blight. This fungus thus had a tremendous influence on the economic, political, and cultural development in Europe and the United States. During World War I, late blight damage to the potato crop in Germany may have helped end the war.

Losses from plant diseases also can have a significant economic impact, causing a reduction in income for crop producers and distributors and higher prices for consumers. In 1993 the United States lost more than one million acres (405,000 hectares) of crops to disease. More than 800,000 acres of wheat succumbed to disease, exacting a monetary loss in the millions of dollars.

Diseases—a normal part of nature. Plant diseases are a normal part of nature and one of many ecological factors that help keep the hundreds of thousands of living plants and animals in balance with one another. Humans have carefully selected and cultivated plants for food, clothing, shelter, fibre, and beauty for thousands of years. Disease is just one of many hazards that must be considered when plants are taken out of their natural environment and grown in pure stands under what are often abnormal conditions.

Many valuable crop and ornamental plants are very susceptible to disease and would have difficulty surviving in nature without human intervention. Cultivated plants are often more susceptible to disease than are their wild relatives. This is because large numbers of the same species or variety, having a uniform genetic background, are grown close together, sometimes over many thousands of square kilometres. A pathogen may spread rapidly under these conditions.

Definitions of plant disease. In general, a plant becomes diseased when it is continuously disturbed by some causal agent that results in an abnormal physiological process that disrupts the plant's normal structure, growth, function, or other activities. This interference with one or more of a plant's essential physiological or biochemical systems elicits characteristic pathological conditions or symptoms.

Plant diseases can be broadly classified according to the nature of their primary causal agent, either infectious or noninfectious. Infectious plant diseases are caused by a pathogenic organism such as a fungus, bacterium, mycoplasma, virus, viroid, nematode, or parasitic flowering plant. An infectious agent is capable of reproducing within or on its host and spreading from one susceptible host to another. Noninfectious plant diseases are caused by unfavourable growing conditions, including extremes of temperature, disadvantageous relationships between moisture and oxygen, toxic substances in the soil or atmosphere, and an excess or deficiency of an essential mineral. Because noninfectious causal agents are not organisms capable of reproducing within a host, they are not transmissible.

In nature, plants may be affected by more than one disease-causing agent at a time. A plant that must contend with a nutrient deficiency or an imbalance between soil moisture and oxygen is often more susceptible to infection by a pathogen; a plant infected by one pathogen is often prone to invasion by secondary pathogens. The combination of all disease-causing agents that affect a plant make up the disease complex. Knowledge of normal growth habits, varietal characteristics, and normal variability of plants within a species—as these relate to the conditions under which the plants are growing—is required for a disease to be recognized.

The study of plant diseases is called plant pathology. Pathology is derived from the two Greek words *pathos* (suffering, disease) and *logos* (discourse, study). Plant pathology thus means a study of plant diseases.

DISEASE DEVELOPMENT AND TRANSMISSION

Pathogenesis and saprogenesis. Pathogenesis is the stage of disease in which the pathogen is in intimate association with living host tissue. Three fairly distinct stages are involved:

1. Inoculation: transfer of the pathogen to the infection court, or area in which invasion of the plant occurs (the infection court may be the unbroken plant surface, a variety of wounds, or natural openings—*e.g.*, stomates [microscopic pores in leaf surfaces], hydathodes [stomatelike openings that secrete water], or lenticels [small openings in tree bark])
2. Incubation: the period of time between the arrival of the pathogen in the infection court and the appearance of symptoms

3. Infection: the appearance of disease symptoms accompanied by the establishment and spread of the pathogen.

One of the important characteristics of pathogenic organisms, in terms of their ability to infect, is virulence. Many different properties of a pathogen contribute to its ability to spread through and to destroy the tissue. Among these virulence factors are toxins that kill cells, enzymes that destroy cell walls, extracellular polysaccharides that block the passage of fluid through the plant system, and substances that interfere with normal cell growth. Not all pathogenic species are equal in virulence—that is, they do not produce the same amounts of the substances that contribute to the invasion and destruction of plant tissue. Also, not all virulence factors are operative in a particular disease. For example, toxins that kill cells are important in necrotic diseases, and enzymes that destroy cell walls play a significant role in soft rot diseases.

Many pathogens, especially among the bacteria and fungi, spend part of their life cycles as pathogens and the remainder as saprophytes.

Saprogenesis is the part of the pathogen's life cycle when it is not in vital association with living host tissue and either continues to grow in dead host tissue or becomes dormant. During this stage, some fungi produce their sexual fruiting bodies; the apple scab (*Venturia inaequalis*), for example, produces perithecia, flask-shaped spore-producing structures, in fallen apple leaves. Other fungi produce compact resting bodies, such as the sclerotia formed by certain root- and stem-rotting fungi (*Rhizoctonia solani* and *Sclerotinia sclerotiorum*) or the ergot fungus (*Claviceps purpurea*). These resting bodies, which are resistant to extremes in temperature and moisture, enable the pathogen to survive for months or years in soil and plant debris in the absence of a living host.

Epiphytotics. When the number of individuals a disease affects increases dramatically, it is said to have become epidemic (meaning "on or among people"). A more precise term when speaking of plants, however, is epiphytotic ("on plants"); for animals, the corresponding term is epizootic. In contrast, endemic (enphytotic) diseases occur at relatively constant levels in the same area each year and generally cause little concern.

Epiphytotics affect a high percentage of the host plant population, sometimes across a wide area. They may be mild or destructive and local or regional in occurrence.

Factors leading to epiphytotics

Epiphytotics result from various combinations of factors, including the right combination of climatic conditions. An epiphytotic may occur when a pathogen is introduced into an area in which it had not previously existed. Examples of this condition include the downy mildews (*Sclerospora* species) and rusts (*Puccinia* species) of corn in Africa during the 1950s, the introduction of the coffee rust fungus into Brazil in the 1960s, and the entrance of the chestnut blight (*Endothia parasitica*) into the United States shortly after 1900. Also, when new plant varieties are produced by plant breeders without regard for all enphytotic diseases that occur in the same area to some extent each year (but which are normally of minor importance), some of these varieties may prove very susceptible to previously unimportant pathogens. Examples of this situation include the development of oat varieties with Victoria parentage, which, although highly resistant to rusts (*Puccinia graminis avenae* and *P. coronata avenae*) and smuts (*Ustilago avenae, U. kolleri*), proved very susceptible to *Helminthosporium* blight (*H. victoriae*), formerly a minor disease of grasses. The destructiveness of this disease resulted in a major shift of oat varieties on 50 million acres in the United States in the mid-1940s. Corn (maize) with male-sterile cytoplasm (*i.e.*, plants with tassels that do not extrude anthers or pollen), grown on 60 million acres in the United States, was attacked in 1970 by a virulent new race of the southern corn leaf blight fungus (*Helminthosporium maydis* race T), resulting in a loss of about 700 million bushels of corn. More recently the new *Helminthosporium* race was widely disseminated and was reported from most continents. Finally, epiphytotics may occur when host plants are cultivated in large acreages where previously little or no land was devoted to that crop.

Epiphytotics may occur in cycles. When a plant disease first appears in a new area, it may grow rapidly to epiphytotic proportions. In time, the disease wanes, and, unless the host species has been completely wiped out, the disease subsides to a low level of incidence and becomes enphytotic. This balance may change dramatically by conditions that favour a renewed epiphytotic. Among such conditions are weather (primarily temperature and moisture), which may be very favourable for multiplication, spread, and infection by the pathogen; introduction of a new and more susceptible host; development of a very aggressive race of the pathogen; and changes in cultural practices that create a more favourable environment for the pathogen.

Environmental factors affecting disease development. Important environmental factors that may affect development of plant diseases and determine whether they become epiphytotic include temperature, relative humidity, soil moisture, soil pH, soil type, and soil fertility.

Temperature. Each pathogen has an optimum temperature for growth. In addition, different growth stages of the fungus, such as the production of spores (reproductive units), their germination, and the growth of the mycelium (the filamentous main fungus body), may have slightly different optimum temperatures. Storage temperatures for certain fruits, vegetables, and nursery stock are manipulated to control fungi and bacteria that cause storage decay, provided the temperature does not change the quality of the products. Little, except limited frost protection, can be done to control air temperature in fields, but greenhouse temperatures can be regulated to check disease development.

Disease forecasting

Knowledge of optimum temperatures, usually combined with optimum moisture conditions, permits forecasting, with a high degree of accuracy, the development of such diseases as blue mold of tobacco (*Peronospora tabacina*), downy mildews of vine crops (*Pseudoperonospora cubensis*) and lima beans (*Phytophthora phaseoli*), late blight of potato and tomato (*Phytophthora infestans*), leaf spot of sugar beets (*Cercospora beticola*), and leaf rust of wheat (*Puccinia recondita tritici*). Effects of temperature may mask symptoms of certain viral and mycoplasmal diseases, however, making them more difficult to detect.

Relative humidity. Relative humidity is very critical in fungal spore germination and the development of storage rots. *Rhizopus* soft rot of sweet potato (*Rhizopus stolonifer*) is an example of a storage disease that does not develop if relative humidity is maintained at 85 to 90 percent, even if the storage temperature is optimum for growth of the pathogen. Under these conditions, the sweet potato root produces suberized (corky) tissues that wall off the *Rhizopus* fungus.

High humidity favours development of the great majority of leaf and fruit diseases caused by fungi and bacteria. Moisture is generally needed for fungal spore germination, the multiplication and penetration of bacteria, and the initiation of infection. Germination of powdery mildew spores occurs best at 90 to 95 percent relative humidity. Diseases in greenhouse crops—such as leaf mold of tomato (*Cladosporium fulvum*) and decay of flowers, leaves, stems, and seedlings of flowering plants, caused by *Botrytis* species—are controlled by lowering air humidity or by avoiding spraying plants with water.

Soil moisture. High or low soil moisture may be a limiting factor in the development of certain root rot diseases. High soil-moisture levels favour development of destructive water mold fungi, such as species of *Aphanomyces, Pythium,* and *Phytophthora.* Excessive watering of houseplants is a common problem. Overwatering, by decreasing oxygen and raising carbon dioxide levels in the soil, makes roots more susceptible to root-rotting organisms.

Diseases such as take-all of cereals (*Ophiobolus graminis*); charcoal rot of corn, sorghum, and soybean (*Macrophomina phaseoli*); common scab of potato (*Streptomyces scabies*); and onion white rot (*Sclerotium cepivorum*) are most severe under low soil-moisture levels.

Soil pH. Soil pH, a measure of acidity or alkalinity, markedly influences a few diseases, such as common scab of potato and clubroot of crucifers (*Plasmodiophora brassicae*). Growth of the potato scab organism is suppressed

at a pH of 5.2 or slightly below (pH 7 is neutral; numbers below 7 indicate acidity, and those above 7 indicate alkalinity). Scab is not normally a problem when the natural soil pH is about 5.2. Some farmers add sulfur to their potato soil to keep the pH about 5.0. Clubroot of crucifers (members of the mustard family, including cabbage, cauliflower, and turnips), on the other hand, can usually be controlled by thoroughly mixing lime into the soil until the pH becomes 7.2 or higher.

Controlling acidity of soils

Soil type. Certain pathogens are favoured by loam soils and others by clay soils. *Phymatotrichum* root rot attacks cotton and some 2,000 other plants in the southwestern United States. This fungus is serious only in black alkaline soils—pH 7.3 or above—that are low in organic matter. *Fusarium* wilt disease, which attacks a wide range of cultivated plants, causes more damage in lighter and higher (topographically) soils. Nematodes are also most damaging in lighter soils that warm up quickly.

Soil fertility. Greenhouse and field experiments have shown that raising or lowering the levels of certain nutrient elements required by plants frequently influences the development of some infectious diseases—for example, fire blight of apple and pear, stalk rots of corn and sorghum, *Botrytis* blights, *Septoria* diseases, powdery mildew of wheat, and northern leaf blight of corn. These diseases and many others are more destructive after application of excessive amounts of nitrogen fertilizer. This condition can often be counteracted by adding adequate amounts of potash, a fertilizer containing potassium.

Requirements for disease development. Infectious disease cannot develop if any one of the following three basic conditions is lacking: (1) the proper environment, the most important environmental factors being the amount and frequency of rains or heavy dews, the relative humidity, and the air and soil temperatures, (2) the presence of a virulent pathogen, and (3) a susceptible host. Effective disease-control measures are aimed at breaking this environment-pathogen-host triangle. Loss resulting from disease is reduced, for example, if the host can be made more resistant or immune through such techniques as plant breeding or genetic engineering. In addition, the environment can be made less favourable for invasion by the pathogen and more favourable for the growth of the host plant. Finally, the pathogen can be killed or prevented from reaching the host. These basic methods of control can be divided into a number of cultural, chemical, and biological practices to help control the disease.

The triangle of environment, pathogen, and host

DIAGNOSIS OF PLANT DISEASES

Rapid and accurate diagnosis of disease is necessary before proper control measures can be suggested. It is the first step in the study of any disease. Diagnosis is largely based on characteristic symptoms (Table 12) expressed by the diseased plant. Identification of the pathogen (by "signs," see Table 13) is also essential to diagnosis.

Three steps involved in diagnosis include careful observation and classification of the facts, evaluation of the facts, and a logical decision as to the cause.

Variable factors affecting diagnosis. A skilled diagnostician must know the normal appearance of an affected plant species, its local air and soil environment, the cultural conditions under which it is growing, the pathogens described for the area, and the disease-developing potential of the pathogen. Diagnosis is best done in the presence of the growing plant. Disease is suspected when, for example, part or all of a plant begins to die. Disease also is indicated when blossoms, leaves, stems, roots, or other plant parts appear abnormal—*i.e.,* misshapen, curled, discoloured, overdeveloped, or underdeveloped. Diseased plants also often fail to respond normally to fertilizing, watering, pruning, insect and mite control, or other recommended practices.

Conditions other than infection with a pathogen, however, may produce similar or identical symptoms. Some of these have been described, but numerous other conditions must be considered as well when plants are adversely affected. For example, an affected plant may not be adapted to the area in which it is growing. It may not be able to withstand the extremes in soil moisture, temperature, wind, light, or humidity of the local situation. Damage to plants may be caused by insects, mites, rodents, pets, or humans. The soil may be poorly drained, gravelly, or overly sandy; it may be covering buried debris—boards, cement blocks, bricks, and mortar; or it may be too dry or otherwise unfavourable for good plant growth. Problems also are caused by high winds, hail, lightning, blowing sand, a heavy load of snow or ice, flooding, fire, ice-removal chemicals, mechanical injury by garden tools or machinery, and fumes from weed-killing chemicals, trash burners, nearby industrial plants, or motor vehicles. The affected plant may have received treatment different from nearby healthy ones—watering, fertilizing, pest control, pruning, or depth of planting are examples. If different species or kinds of plants in the same area have similar symptoms, the chances are that a pathogen is not involved. Most infectious diseases are highly specific for individual or closely related plant species, and similar symptoms on unrelated plants are usually an indication of some environmental factor rather than a disease-causing organism.

Conditions that produce symptoms similar to disease

Examination of leaves is usually considered to be the best starting point in diagnosis. The colour, size, shape, and margins of spots and blights (lesions) are often associated with a particular fungus or bacterium. Many fungi produce "signs" of disease, such as mold growth or fruiting bodies that appear as dark specks in the dead area. Early stages of bacterial infections that develop on leaves or fruits during humid weather often appear as dark and water-soaked spots with a distinct margin and sometimes a halo—a lighter-coloured ring around the spot.

Low winter temperatures and late spring or early fall freezes cause blasting (sudden death) of leaf and flower buds or sudden blighting (discoloration and death) of tender foliage.

Insect-injured leaves usually show evidence of feeding, such as holes, discoloration, stippling, blotching, downward curling, or other deformations.

Scorching of leaf margins and between the veins is common following hot, dry, windy weather. Similar symptoms are produced by an excess of water, an imbalance of essential nutrients, an excess of soluble salts, changes in the soil water table or soil grade, gas or fume injury, and root injury or disease.

Viral diseases, such as mosaics and yellows, are sometimes confused with injury by a hormone-type weed-killer, unbalanced nutrition, and soil that is excessively alkaline or acid. Nearby plant species are often examined to see if similar symptoms are evident on several different types of plants.

Diagnosis of stem system abnormalities

Examination of stems, shoots, branches, and trunk follows a thorough leaf examination. Sunken, swollen, or discoloured areas in the fleshy stem or bark may indicate canker infection by a fungus or bacterium or injury caused by excessively high or low temperatures, hail, tools, equipment, vehicles, or girdling wires.

Fruiting bodies of fungi in or on such areas often indicate secondary infection. Accurate identification of signs as belonging to a pathogenic organism or a secondary or saprophytic one is difficult. Tissues directly infected by pathogenic fungi or bacteria normally show a gradual change in colour or consistency. Injuries, in comparison, are usually well defined with an abrupt change from healthy to affected tissue.

Holes and sawdustlike debris are evidence of boring insects that usually invade woody plants in a low state of vigour. Other borer indications include wilting and dieback (progressive death of shoots that begins at tip and works downward). These symptoms also are produced by fungi and bacteria that invade water- and food-conducting vascular tissue.

Symptoms of wilt-inducing microorganisms include dark streaks in sapwood of wilted branches when the wood is cut through at an angle.

Abnormal suckers or water sprouts on trees can indicate careless pruning, extremes in temperature or water supply, structural injury, or disease.

Galls, which are unsightly overgrowths on stem, branch, or trunk, may indicate crown gall, insect injury, water imbalance between plant and soil, or other factors. Crown

Table 12: Plant Disease Symptoms

	description and causes	examples
Prenecrotic	symptom expression that precedes the death of cells or the disintegration of tissues	
Water-soaking	a water-soaked, translucent condition of tissues caused by water moving from host cells into intercellular spaces	late blight lesions on potato and tomato leaves; bacterial soft rot of fleshy vegetables
Wilting	temporary or permanent drooping of leaves, shoots, or entire plants from lack of water	bacterial wilt of cucumber; *Fusarium* wilt of tomato
Abnormal coloration	yellowing, reddening, bronzing, or purpling in localized areas of leaves where chlorophyll has been destroyed; may be due to a variety of causes	cabbage and aster yellows; halo blight of beans; potassium or phosphorus deficiency
	the presence of two or more colours in leaves and flowers due to a genetic abnormality is called variegation; viral infection results in "flower breaking"	tulip mosaic
Necrotic	localized or general death of cells or disintegration of tissues	
Blast	sudden blighting or death of young buds, flowers, or young fruit; failure to produce fruit or seeds	*Botrytis* blight of peony buds; oat blast
Bleeding	flow of sap, often discoloured, from a split crotch, branch stub, or other wound; usually accompanied by an odour of fermentation	bleeding canker of beech, dogwood, and maple
Blight	sudden or total discoloration and killing of large numbers of blossoms, leaves, shoots, or limbs or the entire plant; usually young tissues are attacked; the disease name is often coupled with the name of the host and the part attacked—blossom blight, twig blight, tip blight	fire blight of pome fruits; *Diplodia* or *Sphaeropsis* tip blight of conifers
Canker	a definite, dead, often sunken or swollen and cracked area on a stem, limb, trunk, tuber, or root surrounded by living tissues	anthracnose of sycamore and brambles; *Nectria* canker of hardwoods; fire blight of pome fruits
Damping-off	decay of seed in soil, rapid death of germinating seedlings before emergence, or emerged seedlings suddenly wilting, toppling over, and dying from rot at or near the soil line	preemergence damping-off and postemergence damping-off; both are common in seedbeds
Dieback	progressive browning and death of shoots, branches, and roots starting at the tips	winter injury; wet soil; excess soil nutrients; girdling cankers; stem or root rots; nematodes
Firing	drying and dying of leaves	nitrogen or potassium deficiency in corn; *Verticillium* wilt of eggplant
Fleck	a small, white to translucent spot or lesion visible through a leaf	ozone injury to many plants; necrotic fleck of lily
Mummification	final stage in certain fruit rots, in which the dried, shriveled, and wrinkled fruit is called a "mummy"	brown rot of stone fruits; black rot of apple
Net necrosis	an irregular crisscrossing of dark brown to black lines giving a netted appearance	in potato tubers of plants with virus leaf roll
Pitting	small dead areas within fleshy or woody tissue that appears healthy externally; definite sunken grooves or pits are formed	virus stem-pitting in apple and peach trunks; stony pit of pear fruit
Rot	decomposition and putrefaction of cells, later of tissues and organs; the rot may be dry, firm, watery, or mushy and characterized by such names as hard rot, soft rot, dry rot, black rot, and white rot	bacterial soft rot; berry rot; bud rot; bulb rot
Scald	blanching of young fruit, foliage, and shoot tissue; generally superficial	sunscald; apple and pear scald
Scorch	sudden death and "burning" of large, indefinite areas in leaves and fruit	toxicity from pesticides and air pollutants; drought; wind; lack or excess of some nutrient
Shot hole	dead spotting of leaves with diseased tissue dropping out, leaving small holes	bacterial spot; *Coryneum* blight of peach
Spot	a definite, localized, round to regular lesion, often with a border of a different colour, characterized as to location (leaf spot, fruit spot) and colour (brown spot, black spot); if numerous or if spots enlarge and merge, a large irregular blotch or blight may develop	gray leaf spot of tomato; black spot of rose; tar spot of maple
Staghead	an advanced form of dieback applied to a tree in which large branches in the upper crown are killed	oak wilt on bur oak; dwarf mistletoe on Douglas fir; *Armillaria* root rot of oak
Streak	narrow, elongated, somewhat superficial necrotic lesions, with irregular margins, on stems or leaf veins	virus streak of pea, raspberry, and tomato; Stewart's wilt of sweet corn
Stripe	narrow, elongated, parallel, necrotic lesions especially in leaf diseases of cereals and grasses	*Helminthosporium* stripe of barley; *Scolecotrichum* brown stripe of forage grasses
Hypoplastic	the underdevelopment of plant cells, tissues, or organs	
Abortion	halting development of an organ after partial differentiation	ergot of rye and other grasses
Chlorosis	yellowing or whitening of normal green tissue due to partial or complete failure of chlorophyll to develop	strawberry and aster yellows; genetic variegation in corn; iron deficiency of azalea
Stunting or dwarfing	the underdevelopment of the plant or some of its organs	dahlia stunt or mosaic; curly top of beans; little-leaf disease of pines
Rosetting	shortening of internodes of shoots and branches, producing a bunchy growth habit	peach and lily rosette
Hyperplastic or hypertrophic	an overdevelopment or overgrowth of plant cells, tissues, or organs; hyperplastic has come to mean an increase in number of cells, hypertrophic an increase in cell size	
Abscission or cast	early dropping of leaves, flowers, or small fruits; usually associated with premature formation of an abscission (separation) cell layer	black spot of rose; early blight of tomato; apple scab
Callus	overgrowth of tissues, often at margins of a canker or wound	*Nectria* canker of hardwoods; stem pitting of peach
Curl	distortion and crinkling of leaves or shoots resulting from unequal cell growth of opposite sides or in certain tissues	tobacco and tomato mosaic; leaf roll of potato; peach leaf curl
Epinasty	downward or outward curling and bending of a leaf or petiole	2,4-D injury to broadleaf plants; *Fusarium* wilt of tomato
Fasciation, or witches'-broom	a distortion that results in a dense, bushy overgrowth of thin, flattened, and sometimes curved shoots, flowers, fruit, and roots at a common point; usually due to adventitious (abnormally located) development of organs	witches'-broom of hackberry; hairy root of apple; leaf gall or fasciation of geranium (see also *Rosetting* under *Hypoplastic* in this table)
Metamorphosis or transformation	development of more or less normal tissues or organs in an abnormal location	crazy-top of corn and sorghum; formation of aerial potato tubers
Proliferation	continued development of an organ after it would normally stop growing	adventitious shoots in China aster and chrysanthemum from aster yellows mycoplasma
Russeting	usually a brownish, superficial roughening or corking of the epidermis of leaves, fruit, tubers, or other organs; often due to suberization (cork development) of cells following injury	spray or weather injury to apples; sweet potato scurf
Scab	roughened to crustlike, more or less circular, slightly raised or sunken lesions on the surface of leaves, stems, fruit, or tubers	apple, peach, and cucumber scab; common scab of potato
Gall, knot, or tumefaction	formation of local, fleshy to woody outgrowths or swellings; the outgrowth is often composed of unorganized cells	crown gall; black knot of plum; *Fusiform* gall rust of pine; nematode galls

gall is infectious and develops as rough, roundish galls at wounds, resulting from grafting, pruning, or cultivating.

Wood-decay fungi also enter unprotected wounds, resulting in discoloured, water-soaked, spongy, stringy, crumbly, or hard rots of living and dead wood. External evidence of wood-decay fungi are clusters of mushrooms (or toadstools) and hoof- or shelf-shaped fungal fruiting structures, called conks, punks, or brackets.

Aboveground symptoms of many root problems look alike. They include stunting of leaf and twig growth, poor foliage colour, gradual or sudden decline in vigour and productivity, shoot wilting and dieback, and even rapid death of the plant. The causes include infectious root and crown rot; nematode, insect, or rodent feeding; low temperature or lightning injury; household gas injury; poor soil type or drainage; change in soil grade; or massive removal of roots in digging utility trenches and construction.

Abnormal root growth is revealed by comparison with healthy roots. Some nematodes, such as root knot (*Meloidogyne* species), produce small to large galls in roots; other species cause affected roots to become discoloured, stubby, excessively branched, and decayed. Bacterial and fungal root rots commonly follow feeding by nematodes, insects, and rodents.

Diagnosis of a disease complex, one with two or more causes, is usually difficult and requires separation and identification of the individual causes.

Symptoms. The variety of symptoms, the internal and external expressions of disease, that result from any disease form the symptom complex, which, together with the accompanying signs, makes up the syndrome of the disease.

Classification of symptoms

Generalized symptoms may be classified as local or systemic, primary or secondary, and microscopic or macroscopic. Local symptoms are physiological or structural changes within a limited area of host tissue, such as leaf spots, galls, and cankers. Systemic symptoms are those involving the reaction of a greater part or all of the plant, such as wilting, yellowing, and dwarfing. Primary symptoms are the direct result of pathogen activity on invaded tissues (*e.g.*, swollen "clubs" in clubroot of cabbage and "galls" formed by feeding of the root-knot nematode). Secondary symptoms result from the physiological effects of disease on distant tissues and uninvaded organs (*e.g.*, wilting and drooping of cabbage leaves in hot weather resulting from clubroot or root knot). Microscopic disease symptoms are expressions of disease in cell structure or cell arrangement seen under a microscope. Macroscopic symptoms are expressions of disease that can be seen with the unaided eye. Specific macroscopic symptoms are classified under one of four major categories: prenecrotic, necrotic, hypoplastic, and hyperplastic or hypertrophic. These categories reflect abnormal effects on host cells, tissues, and organs that can be seen without a hand lens or microscope. See Table 12 for examples of the main disease symptoms that are classified in these four categories.

Signs. Besides symptoms, the diagnostician recognizes signs characteristic of specific diseases. Signs are either structures formed by the pathogen or the result of interaction between pathogen and host—*e.g.*, ooze of fire blight bacteria, slime flux from wetwood of elm, odour of tissues affected with bacterial soft rot. See Table 13 for the most frequently encountered signs of pathogen presence and examples of organisms producing them.

Technological advances in the identification of pathogenic agents. Developments in microscopy, serology and immunology, molecular biology, and laboratory instrumentation have resulted in many new and sophisticated laboratory procedures for the identification of plant pathogens, particularly bacteria, viruses, and viroids. The techniques of traditional scanning microscopy and transmission electron microscopy have been applied to immunosorbent electron microscopy, in which the specimen is subject to an antigen-antibody reaction before observation and scanning tunneling microscopy, which provides information about the surface of a specimen by constructing a three-dimensional image.

Serological tests have been made more specific and convenient to perform since the discovery of a technique to produce large quantities of monoclonal antibodies, which bind to only one specific antigen. The sensitivity of antigen-antibody detection has been significantly increased by a radioimmunoassay (RIA) procedure. In this procedure a "known" antigen is overlayed on a plastic plate to which antigen molecules adhere. A solution of antibody is applied to the same plate; if the antibody is specific to the antigen, it will combine with it. This is followed by the application of radioactively labeled anti-antibody, which is allowed to react and then washed off. The radioactivity that remains on the plate is a measure of the amount of antibody that combined with the known fixed antigen. Another highly sensitive immunoassay is the enzyme-linked immunosorbent assay (ELISA). In principle this assay is similar to the RIA except that an enzyme system, instead of radioactivity, is used as an indicator of an antigen-antibody combination.

New analytic methods in molecular biology have made genetic studies for the characterization and identification of bacteria more practical. The DNA hybridization technique is an example. A strand of DNA from a known species (the probe) is radioactively labeled and "mixed" with DNA from an unidentified species. If the probe and the unknown DNA are from identical species, they will have complementary DNA sequences that enable them to bind to one another. Bound to DNA from the unknown species, the probe acts as a marker and identifies the bacteria.

The growing demand for quick identification of microorganisms has resulted in the development of instrumentation for automated technology that allows a large number of tests to be performed on many specimens in a short period of time. The results are read automatically and analyzed by a computer program to identify the pathogens.

PRINCIPLES OF DISEASE CONTROL

Successful disease control requires thorough knowledge of the causal agent and the disease cycle, host-pathogen interactions in relation to environmental factors, and cost. Disease control starts with the best variety, seed, or planting stock available and continues throughout the life of the plant. For harvested crops, disease control extends through transport, storage, and marketing. Relatively few diseases are controlled by a single method; the majority require several approaches. These often need to be integrated into a broad program of biological, cultural, and chemical methods to control as many different pests—including insects, mites, rodents, and weeds—on a given crop as possible.

Most control measures are directed against inoculum of the pathogen and involve the principles of exclusion and avoidance, eradication, protection, host resistance and selection, and therapy.

Exclusion and avoidance. The principle of exclusion and avoidance is to keep the pathogen away from the growing host plant. This practice commonly excludes pathogens by disinfection of plants, seeds, or other parts, using chemicals or heat. Inspection and certification of seed and other planting stock help ensure freedom from disease. For gardeners this involves sorting bulbs or corms before planting and rejecting diseased plants. Federal and state plant quarantines, or embargoes, have been established to prevent introduction of potentially destructive pathogens into areas currently free of the disease. More than 150 countries now have established quarantine regulations.

Eradication. Eradication is concerned with elimination of the disease agent after it has become established in the area of the growing host or has penetrated the host. Such measures include crop rotation, destruction of the diseased plants, elimination of alternate host plants, pruning, disinfection, and heat treatments.

Crop rotation with nonsusceptible crops "starves out" bacteria, fungi, and nematodes with a restricted host range. Some pathogens can survive only as long as the host residue persists, usually no more than a year or two. Many pathogens, however, are relatively unaffected by rotation because they become established as saprophytes in the soil (*e.g.*, *Fusarium* and *Pythium* species; *Rhizoctonia solani;* and the potato scab actinomycete, *Streptomyces scabies*) or their propagative structures remain dormant but viable

Table 13: Signs of Pathogen Presence in Diseased Plants*

sign	description	examples
Acervulus	a shallow, saucer-shaped fungal structure that bears asexual spores (conidia); it is usually formed below the cuticle or epidermis of leaves, stems, and fruits, later rupturing the surface and exposing its spore-bearing surface	anthracnose of muskmelon and tomato; *Marssonina* leaf spot and twig blight of poplar
Apothecium	a disk-, saucer-, or cup-shaped fungal structure that produces sexual spores (ascospores); it is often stalked and fleshy	brown rot of stone fruits; *Sclerotinia* white mold of fleshy vegetables
Cleistothecium	a speck-sized, black fruiting body completely enclosing sexual spores	many powdery mildew fungi
Conidiophores	asexual fungal structures of various colours that bear conidia and appear powdery, velvety, or downy en masse; they often cover lesions of leaf, stem, or fruit	*Botrytis* blight or gray mold of many flowers; *Penicillium* mold of citrus fruit; downy mildew of grape
Conk or punk	fruiting body (sporophore) of wood-rotting fungi that produces tremendous numbers of spores (up to 100 billion per day); conks are usually large and woody and are found on tree stumps, branches, or trunks	*Fomes* and *Polyporus* wood rots of hardwoods and conifers
Mushrooms (toadstools)	fleshy, umbrella-shaped fruiting bodies of wood-decay fungi	*Armillaria* and *Clitocybe* root rots
Mycelium	the vegetative body of a fungus, which is composed of a mass of branched filaments (hyphae) often interwoven into a feltlike or woolly mass	*Rhizopus* soft rot of sweet potato and leak of strawberry; *Sclerotinia* white mold of beans
Nematode cysts	round to lemon-shaped, speck-sized bodies, white to brown in colour, are diagnostic for cyst nematodes; they are often evident on the root surface	sugar beet, soybean, and clover cyst nematodes
Odours	the process of host colonization and many pathogens give off characteristic odours	bacterial soft rot; stinking smut or bunt of wheat; slime flux of elm
Ooze or exudate	droplets of bacteria or fungal spores, usually mixed with host cell decomposition products, found on surfaces of lesions	ooze from fire blight; scab on cucumber fruit; cut stem of cucumber affected with bacterial wilt
Perithecium	speck-sized fungal fruiting body that produces large numbers of sexual spores; perithecia are dark-coloured, round to flask-shaped, usually partially buried in diseased tissue; they resemble pycnidia	apple and pear scab; *Gibberella* stalk and ear rot of corn
Powdery mildew	white, powdery to mealy, superficial growths of mycelia and conidiophores on surfaces of leaves, stems, flowers, and fruit	powdery mildew diseases of bluegrass, phlox, zinnia, and rose (see also *Cleistothecium*, this table)
Pycnidium	speck-sized fungal fruiting body that produces large numbers of asexual spores (conidia); pycnidia are dark-coloured, round to flask-shaped, usually partially buried in diseased tissue; they resemble perithecia	*Septoria* leaf spots; *Diplodia* stalk rot of corn
Rhizomorphs	cordlike or rootlike strands, composed of a bundle of closely intertwined hyphae, by which certain fungi make their way through soil and over or under bark of woody plants	*Armillaria* and *Clitocybe* root rots; *Sclerotium rolfsii* stem rot of peanuts
Sclerotium	brown to black, compact, hard resting body of certain fungi with a rindlike covering; the size varies from a fly speck to a large sweet potato depending on the fungus forming it	ergot of rye; onion white rot; *Verticillium albo-atrum*
Seed	dodder seed is a sign of this parasitic flowering plant when found in clover or alfalfa seed	dodder (*Cuscuta*, about 170 species)
Sorus (pustule)	a compact mass of spores, or a cluster of sporangia (spore-bearing structures), produced in or on the host by fungi causing such diseases as white rust, smut, and true rust; before rupturing, the sorus is normally covered by host epidermis	white rust of crucifers; corn and bluegrass smuts; black stem rust of cereals
Spores	microscopic, usually single- or few-celled reproductive bodies of fungi corresponding in function to seeds of higher plants; spores vary greatly in size, shape, and colour; they are asexually produced or result from sexual processes; asexual spores may be formed directly from vegetative hyphae but often are produced in special fruiting structures (*e.g.*, acervulus, coremium, pycnidium, and sporodochium)	
Sporodochium	a cushion-shaped stroma covered with conidiophores bearing asexual spores; found scattered in leaf, stem, and fruit lesions	*Cercospora* leaf spot of celery and sugar beet; brown rot of stone fruits; *Fusarium* blight of bluegrass
Stroma	a crustlike or cushionlike mass of fungal hyphae often intermingled with host tissue on or in which spores are produced—usually in reproductive bodies	tar spot of maple and sycamore
Synnema or coremium	a tight cluster of erect conidiophores forming an elongated column on which asexual spores are borne	Dutch elm disease; oak wilt; black rot of sweet potato

*The structures listed are formed by the pathogen.

for many years (*e.g.*, cysts of cyst nematodes, sporangia of the cabbage clubroot fungus, and onion smut spores).

Burning and destruction

Burning, deep plowing of plant debris, and fall spraying are used against such diseases as leaf blights of tomato, Dutch elm disease, and apple scab. Destruction of weed hosts also helps control such viral diseases as cucumber mosaic and curly top. For fungi whose complete life cycle requires two different host species, such as black stem rust of cereals and white-pine blister rust, destruction of alternate hosts is effective. Destruction of diseased plants helps control Dutch elm disease, oak wilt, and peach viral diseases—mosaic, phony peach, and rosette. Elimination of citrus canker in the southeastern United States has been one of the few successful eradication programs in history. Infected trees were sprayed with oil and burned.

Pruning and excision of a diseased portion of the plant have aided in reducing inoculum sources for canker and wood-rot diseases of shade trees and fire blight of pome fruits. Disinfection of contaminated tools, as well as packing and shipping containers, controls a wide range of diseases. Direct application of dry or wet heat is used to obtain seeds, bulbs, other propagative materials, and even entire plants free of viruses, nematodes, and other pathogens.

Protection. The principle of protection involves placing a barrier between the pathogen and the susceptible part of the host to shield the host from the pathogen. This can be accomplished by regulation of the environment, cultural and handling practices, control of insect carriers, and application of chemical pesticides.

Regulation of the environment. Selection of outdoor growing areas where weather is unfavourable for disease is a method of controlling disease by regulating the environment. Control of viral diseases of potato, for example, can be accomplished by growing the seed crop in northern regions where low temperatures are unfavourable for the aphid carriers. Another environmental factor that can be brought under control is the storage and in-transit environment. A variety of postharvest diseases of potato, sweet potato, onion, cabbage, apple, pear, and other crops are controlled in storage and shipment by keeping humidity and temperature low and by reducing the quantity of ethylene and other natural gases in storage houses.

Cultural practices. Selection of the best time and depth of seeding and planting is an effective cultural practice that reduces disease impact. Shallow planting of potatoes may help to prevent *Rhizoctonia* canker. Early fall seeding of winter wheat may be unfavourable for seedling infection by wheat-bunt teliospores. Cool-temperature crops can be grown in soils infested with root-knot nematode and harvested before soil temperatures become favourable for nematode activity. Adjustment of soil moisture is another

Temperature, moisture, and soil pH

cultural practice of widespread usefulness. For example, seed decay, damping-off (the destruction of seedlings at the soil line), and other seedling diseases are favoured by excessively wet soils. The presence of drain tiles in poorly drained fields and the use of ridges or beds for plants are often beneficial. Adjustment of soil pH also leads to control of some diseases. Common potato scab can be controlled by adjusting the pH to 5.2 or below; other acid-tolerant plants then must be used in crop rotation, however.

Regulation of fertility level and nutrient balance. Potash and nitrogen, and the balance between the two, may affect the incidence of certain bacterial, fungal, and viral diseases of corn, cotton, tobacco, and sugar beet. A number of microelements, including boron, iron, zinc, manganese, magnesium, copper, sulfur, and molybdenum, may cause noninfectious diseases of many crop and ornamental plants. Adjusting the soil pH, adding chelated (bound or enclosed in large organic molecules) or soluble salts to the soil, or spraying the foliage with these or similar salts is a corrective measure.

Handling practices. Late blight on potato tubers can be controlled by delaying harvest until the foliage has been killed by frost, chemicals, or mechanical beaters. Avoidance of bruises and cuts while digging, grading, and packing potatoes, sweet potatoes, and bulb crops also reduces disease incidence.

Control of insect vectors. There are many examples in which losses by bacteria, viruses, and mycoplasma-like disease agents can be reduced by controlling aphids, leafhoppers, thrips, beetles, and other carriers of these agents.

Chemical control. A variety of chemicals are available that have been designed to control plant diseases by inhibiting the growth of or by killing the disease-causing pathogens. Chemicals used to control bacteria (bactericides), fungi (fungicides), and nematodes (nematicides) may be applied to seeds, foliage, flowers, fruit, or soil. They prevent or reduce infections by utilizing various principles of disease control. Eradicants are designed to kill a pathogen that may be present in the soil, on the seeds, or on vegetative propagative organs, such as bulbs, corms, and tubers. Protectants place a chemical barrier between the plant and the pathogen. Therapeutic chemicals are applied to combat an infection in progress.

Eradicants and protectants

Soil treatments are designed to kill soil-inhabiting nematodes, fungi, and bacteria. This eradication can be accomplished using steam or chemical fumigants. Soilborne nematodes can be killed by applying granular or liquid nematicides. Most soil is treated well before planting; however, certain fungicides can be mixed with the soil at planting time.

Seeds, bulbs, corms, and tubers are frequently treated with chemicals to eradicate pathogenic bacteria, fungi, and nematodes and to protect the seeds against organisms in the soil—mainly fungi—that cause decay and damping-off. Seeds are often treated with systemic fungicides, which are absorbed and provide protection for the growing seedling.

Protective sprays and dusts applied to the foliage and fruit of crops and ornamentals include a wide range of organic chemicals designed to prevent infection. Protectants are not absorbed by or translocated through the plant; thus they protect only those parts of the plant treated before invasion by the pathogen. A second application is often necessary because the chemical may be removed by wind, rain, or irrigation or may be broken down by sunlight. New, untreated growth also is susceptible to infection. New chemicals are constantly being developed.

Biological control. Biological control of plant diseases involves the use of organisms other than humans to reduce or prevent infection by a pathogen. These organisms are called antagonists; they may occur naturally within the host's environment, or they may be purposefully applied to those parts of the potential host plant where they can act directly or indirectly on the pathogen.

Although the effects of biological control have long been observed, the mechanisms by which antagonists achieve control is not completely understood. Several methods have been observed: some antagonists produce antibiotics that kill or reduce the number of closely related pathogens; some are parasites on pathogens; and others simply compete with pathogens for available food.

Cultural practices that favour a naturally occurring antagonist and exploit its beneficial action often are effective in reducing disease. One technique is to incorporate green manure, such as alfalfa, into the soil. Saprophytic microorganisms feed on the green manure, depriving potential pathogens of available nitrogen. Another practice is to make use of suppressive soils—those in which a pathogen is known to persist but causes little damage to the crop. A likely explanation for this phenomenon is that suppressive soils harbour antagonists that compete with the pathogen for food and thereby limit the growth of the pathogen population.

Other antagonists produce substances that inhibit or kill potential pathogens occurring in close proximity. An example of this process, called antibiosis, is provided by marigold (*Tagetes* species) roots, which release terthienyls, chemicals that are toxic to several species of nematodes and fungi.

Antibiosis

Only a few antagonists have been developed specifically for use in plant-disease control. Citrus trees are inoculated with an attenuated strain of tristeza virus, which effectively controls the virulent strain that causes the disease. An avirulent strain of *Agrobacterium radiobacter* (K84) can be applied to plant wounds to prevent crown gall caused by infection with *Agrobacterium tumefaciens*. Many more specific antagonists are being investigated and hold much promise for future control of disease.

Therapy. Therapeutic measures have been used much less often in plant pathology than in human or animal medicine. The recent development of systemic fungicides such as oxathiins, benzimidazoles, and pyrimidines have enabled growers to treat many plants after an infection has begun. Systemic chemicals are absorbed by and translocated within the plant, restricting the spread and development of pathogens by direct or indirect toxic effects or by increasing the ability of the host to resist infection.

Antibiotics have been developed to control various plant diseases. Most of these drugs are absorbed by and translocated throughout the plant, providing systemic therapy. Streptomycin is used against a variety of bacterial pathogens; tetracycline is able to control the growth of certain mycoplasmas; and cycloheximides offer effective control for certain diseases caused by fungi.

Host resistance and selection. Disease-resistant varieties of plants offer an effective, safe, and relatively inexpensive method of control for many crop diseases. Most available commercial varieties of crop plants bear resistance to at least one, and often several, pathogens. Resistant or immune varieties are critically important for low-value crops in which other controls are unavailable, or their expense makes them impractical. Much has been accomplished in developing disease-resistant varieties of field crops, vegetables, fruits, turf grasses, and ornamentals. Although great flexibility and potential for genetic change exist in most economically important plants, pathogens are also flexible. Sometimes, a new plant variety is developed that is highly susceptible to a previously unimportant pathogen.

Variable resistance. Resistance to disease varies among plants; it may be either total (a plant is immune to a specific pathogen) or partial (a plant is tolerant to a pathogen, suffering minimal injury). The two broad categories of resistance to plant diseases are vertical (specific) and horizontal (nonspecific). A plant variety that exhibits a high degree of resistance to a single race, or strain, of a pathogen is said to be vertically resistant; this ability usually is controlled by one or a few plant genes. Horizontal resistance, on the other hand, protects plant varieties against several strains of a pathogen, although the protection is not as complete. Horizontal resistance is more common and involves many genes.

Vertical and horizontal resistance

Obtaining disease-resistant plants. Several means of obtaining disease-resistant plants are commonly employed alone or in combination. These include introduction from an outside source, selection, and induced variation. All three may be used at different stages in a continuous process; for example, varieties free from injurious insects or plant diseases may be introduced for comparison with

local varieties. The more promising lines or strains are then selected for further propagation, and they are further improved by promoting as much variation as possible through hybridization or special treatment. Finally, selection of the plants showing greatest promise takes place. Developing disease-resistant plants is a continuing process.

Special treatments for inducing gene changes include the application of mutation-inducing chemicals and irradiation with ultraviolet light and X rays. These treatments commonly induce deleterious genetic changes, but, occasionally, beneficial ones also may occur.

Methods used in breeding plants for disease resistance are similar to those used in breeding for other characters except that two organisms are involved—the host plant and the pathogen. Thus, it is necessary to know as much as possible about the nature of inheritance of the resistant characters in the host plant and the existence of physiological races or strains of the pathogen.

The use of genetic engineering in developing disease-resistant plants. The techniques of genetic engineering can be used to manipulate the genetic material of a cell in order to produce a new characteristic in an organism. Genes from plants, microbes, and animals can be recombined (recombinant DNA) and introduced into the living cells of any of these organisms.

Organisms that have had genes from other species inserted into their genome (the full complement of an organism's genes) are called transgenic. The production of pathogen-resistant transgenic plants has been achieved by this method; certain genes are inserted into the plant's genome that confer resistance to such pathogens as viruses, fungi, and insects. Transgenic plants that are tolerant to herbicides and that show improvements in other qualities also have been developed.

Apprehension about the release of transgenic plants into the environment exists, and measures to safeguard the application of this technology have been adopted. In the United States several federal agencies, such as the U.S. Department of Agriculture, the Food and Drug Administration, and the Environmental Protection Agency, regulate the use of genetically engineered organisms. From 1987 to 1994 the U.S. Department of Agriculture issued more than 1,300 permits or notifications to allow transgenic plants to be evaluated in the field. With proper regulation, this technology holds great promise for making substantial advances in the control of plant diseases.

Classification of plant diseases by causal agent

Plant diseases are often classified by their physiological effects or symptoms. Many diseases, however, produce practically identical symptoms and signs but are caused by very different microorganisms or agents, thus requiring completely different control methods. Classification according to symptoms is also inadequate because a causal agent may induce several different symptoms, even on the same plant organ, which often intergrade. Classification may be according to the species of plant affected. Host indexes (lists of diseases known to occur on certain hosts in regions, countries, or continents) are valuable in diagnosis. When an apparently new disease is found on a known host, a check into the index for the specific host often leads to identification of the causal agent. It is also possible to classify diseases according to the essential process or function that is adversely affected. The best and most widely used classification of plant diseases is based on the causal agent, such as a noninfectious agent or an infectious agent (*i.e.*, a virus, viroid, mycoplasma, bacterium, fungus, nematode, or parasitic flowering plant).

Use of the host index

NONINFECTIOUS DISEASE-CAUSING AGENTS

Noninfectious diseases, which sometimes arise very suddenly, are caused by the excess, deficiency, nonavailability, or improper balance of light, air circulation, relative humidity, water, or essential soil elements; unfavourable soil moisture-oxygen relations; extremes in soil acidity or alkalinity; high or low temperatures; pesticide injury; other poisonous chemicals in air or soil; changes in soil grade; girdling of roots; mechanical and electrical agents; and soil compaction. In addition, unfavourable preharvest and storage conditions for fruits, vegetables, and nursery stock often result in losses. The effects of noninfectious diseases can be seen on a variety of plant species growing in a given locality or environment. Many diseases and injuries caused by noninfectious agents result in heavy loss but are difficult to check or eliminate because they frequently reflect ecological factors beyond human control. Symptoms may appear several weeks or months after an environmental disturbance.

Injuries incurred from accidents, poisons, or adverse environmental disturbances often result in damaged tissues that weaken a plant, enabling bacteria, fungi, or viruses to enter and add further damage. The cause may be obvious (lightning or hail), but often it is obscure. Symptoms alone are often unreliable in identifying the causal factor. A thorough examination of recent weather patterns, the condition of surrounding plants, cultural treatments or disturbances, and soil and water tests can help reveal the nature of the disease. For examples of nonpathogenic plant diseases, see Figure 1.

Adverse environment. High temperatures may scald corn, cotton, and bean leaves and may induce formation of cankers at the soil surface of tender flax, cotton, and peanut plants. Frost injury is relatively common, but temperatures just above freezing also may cause damage, such as net necrosis (localized tissue death) in potato tubers and "silvering" of corn leaves. Isolated, thin-barked trees growing in northern climates and subjected to frequent thawing by day and freezing by night may develop dead bark cankers or vertical frost cracks on the south or southwest sides of the trunk. Alternate freezing and thawing, heaving, low air moisture, and smothering under an ice-sheet cover are damaging to alfalfa, clovers, strawberries, and grass on golf greens. Legume crowns commonly split under these conditions and are invaded by decay-forming fungi.

Low-temperature injury

The drought and dry winds that often accompany high temperatures cause stunting, wilting, blasting, marginal scorching of leaves, and dieback of shoots. Leaf scorch is common on trees in exposed locations following hot, dry, windy weather when water is lost from leaves faster than it is absorbed by roots. Leaf scorch and sudden flower drop are common indoor plant problems because the humidity in a home, an apartment, or an office is usually below 30 percent. Similar symptoms are caused by a change in soil grade, an altered water-table level, a compacted and shallow soil, paved surface over tree roots, temporary flooding or a waterlogged (oxygen-deficient) soil, girdling tree roots, salt spray near the ocean, and an injured or diseased root system. Injured plants are often very susceptible to air and soil pathogens and secondary invaders.

Blossom-end rot of tomato and pepper is prevalent when soil moisture and temperature levels fluctuate widely and calcium is low.

Poor aeration may cause blackheart in stored potatoes. Accumulation of certain gases from the respiration of apples in storage may produce apple scald and other disorders.

All plants require certain mineral elements to develop and mature in a healthy state. Macronutrients such as nitrogen, potassium, phosphorus, sulfur, calcium, and magnesium are required in substantial quantities, while micronutrients or trace elements such as boron, iron, manganese, copper, zinc, and molybdenum are needed in much smaller quantities. When the supply of any essential nutrient falls below the level required by the plant, a deficiency occurs, leading to symptoms that include stunting of plants; scorching or malformation of leaves; abnormal coloration; premature leaf, bud, and flower drop; delayed maturity or failure of flower and fruit buds to develop; and dieback of shoots.

Nutrient deficiencies

Symptoms of nutrient deficiencies vary depending on the nutrients involved, the stage of plant growth, soil moisture, and other factors; they often resemble symptoms caused by infectious agents such as bacteria or viruses.

The availability of water may affect nutrient uptake by the plant. Blossom-end rot of tomato, a disease associated with a deficiency of calcium, may occur if the water sup-

ply is irregular, even if an adequate amount of calcium is in the soil. This discontinuity in availability of water will inhibit uptake of the calcium in a quantity sufficient to nourish a fast-growing tomato plant. Necrosis at the blossom end of the fruit results. This situation generally disappears when water conditions improve.

Excess minerals can damage plants either directly, causing stunting, deformities, or dieback, or indirectly by interfering with the absorption and use of other nutrients, resulting in subsequent deficiency symptoms. A superabundance of nitrogen, for example, may cause deficiency symptoms of potassium, zinc, or other nutrient elements; a lack of or delay in flower and fruit development; and a predisposition to winter injury. If potassium is high, calcium and magnesium deficiencies may occur.

The pH of a soil has a dramatic impact on nutrient availability to plants. Most plants will grow in a soil with a pH between 4.0 and 8.0. In acidic soils some nutrients are far more available and may reach concentrations that are toxic or that inhibit absorption of other nutrients, while other minerals become chemically bound and unavailable to plants. A similar situation exists in alkaline soils, although different minerals are affected. Oats planted in alkaline soils that actually contain a sufficient amount of manganese may develop the manganese-deficiency disease gray speck. This occurs because an elevated soil pH causes manganese to react with oxygen to produce manganese dioxide, a form of the nutrient that is insoluble to plants.

An excess of water-soluble salts is a common problem with houseplants. Salt concentrations may build up as a whitish crust on soil and container surfaces of potted plants following normal evaporation of water over a period of time. Symptoms include leaf scorching, bronzing, yellowing and stunting, and wilting, plus root and shoot dieback. Damage from soluble salts is also common in arid regions and in regions where ice-control chemicals are applied heavily.

Several nonparasitic diseases (*e.g.,* oat blast, weakneck of sorghum, straighthead of rice, and crazy-top of cotton) are caused by combinations of environmental factors—*e.g.,* high temperatures, moisture stress or poor irrigation practices, imbalance of mineral nutrients, and reduced light.

Environmental disturbances alter the normal physiology of the plant, activity of pathogens, and host-pathogen interactions.

Toxic chemicals. Many complex chemicals are routinely applied to plants to prevent attack by insects, mites, and pathogens; to kill weeds; or to control growth. Serious damage may result when fertilizers, herbicides, fumigants, growth regulators, antidesiccants, insecticides, miticides, fungicides, nematicides, and surfactants (substances with enhanced wetting, dispersing, or cleansing properties, such as detergents) are applied at excessive rates or under hot, cold, or slow-drying conditions.

Some pollutants are the direct products of industry and fuel combustion, while others are the result of photochemical reactions between products of combustion and naturally occurring atmospheric compounds. The major pollutants toxic to plants are sulfur dioxide, fluorine, ozone, and peroxyacetyl nitrate.

Sulfur dioxide results primarily from the burning of large amounts of soft coal and high-sulfur oil. It is toxic to a wide range of plants at concentrations as low as 0.25 part per million (ppm) of air (*i.e.,* on a volume basis, one part per million represents one volume of pure gaseous toxic substance mixed in one million volumes of air) for 8 to 24 hours. Gaseous and particulate fluorides are more toxic to sensitive plants than is sulfur dioxide because they are accumulated by leaves. They are also toxic to animals that feed on such foliage. Fluorine injury is common near metal-ore smelters, refineries, and industries making fertilizers, ceramics, aluminum, glass, and bricks.

Ozone and peroxyacetyl nitrate injury (also called oxidant injury) are more prevalent in and near cities with heavy traffic problems. Exhaust gases from internal combustion engines contain large amounts of hydrocarbons (substances that principally contain carbon and hydrogen molecules—gasoline, for example). Smaller amounts of unconsumed hydrocarbons are formed by combustion of fossil fuels (*e.g.,* coal, oil, natural gas) and refuse burning. Ozone, peroxyacetyl nitrate, and other oxidizing chemicals (smog) are formed when sunlight reacts with nitrogen oxides and hydrocarbons. This pollutant complex is damaging to susceptible plants many kilometres from its source. Ozone and peroxyacetyl nitrate are capable of causing injury if present at levels of 0.01 to 0.05 part per million for several hours.

Photochemical air pollutants

Physical injury. Lightning, hail, high winds, ice and snow loads, machinery, insect and animal feeding, and various cultural practices may seriously injure plants or plant products. With the exception of lightning, which may cause death of trees and succulent crop plants in limited areas, such injury does not usually kill plants. Wounds are created, however, through which pathogens may enter.

INFECTIOUS DISEASE-CAUSING AGENTS

Plants are subject to infection by thousands of species from very diverse groups of organisms. Most are microscopic, but a few are macroscopic. The infectious agents, as previously mentioned, are called pathogens and can be grouped as follows: viruses and viroids, bacteria (including mycoplasmas and spiroplasmas, collectively referred to as mycoplasma-like organisms [MLOs]), fungi, nematodes, and parasitic seed plants.

Diseases caused by viruses and viroids. *General characteristics.* Viruses and viroids are the smallest of the infec-

tious agents. The structurally mature infectious particle is called a virion. Virions range in size from approximately 20 nanometres (0.0000008 inch) to 250–400 nanometres and are of various shapes (see also VIRUSES). Viroids differ from viruses in that they have no structural proteins, such as those that form the protein coat (capsid) of the virus.

Both viruses and viroids are obligate parasites—*i.e.,* they are able to multiply or replicate only within a living cell of a particular host. A single plant species may be susceptible to infection by several different viruses or viroids. Major disease of important food crops such as potato, tomato, wheat, oats, rice, corn, peach, orange, sugar beet, sugarcane, and palm result from viral infection. Diseases are generally most serious in plants that are propagated vegetatively, or asexually—*i.e.,* grown from cuttings, cut divisions, sprouts, and other plant material—rather than grown from seeds (sexually propagated). For examples of diseases caused by viruses, see Figure 2.

Symptoms. The symptoms of viral and viroid plant diseases fall into four groups: (1) change in colour—yellowing, green and yellow mottling, and vein clearing; (2) malformations—distortion of leaves and flowers, rosetting, proliferation and witches'-brooms (abnormal proliferation of shoots), and little or no leaf development between the veins; (3) necrosis—leaf spots, ring spots, streaks, wilting or drooping, and internal death, especially of phloem (food-conducting) tissue; and (4) stunting or dwarfing of leaves, stems, or entire plants. Rarely they may kill the host in a short time (*e.g.,* spotted wilt and curly top of tomato). More commonly they cause reduced yield and lower quality of product.

Figure 2: *Plant diseases caused by viruses.*
(Left) Leaf of *Abutilon* infected by abutilon mosaic virus. (Right) Russet potatoes with corky ring spot, which is caused by tobacco rattle virus.

In many cases, virus-infected plants are more susceptible to root rots, stem or stalk rots, seedling blights, and possibly other types of diseases.

Some plants may carry one or more viruses and show no symptoms; thus, they are latent carriers and a source of infection for other plants. Symptoms of certain virus-infected plants, such as geraniums, may be masked at high temperatures. Virus symptoms reappear when the weather cools.

Virus strains

For convenience, viral/viroid diseases are often grouped together generally by symptoms, regardless of true viral/viroid relationships. Viruses also can be grouped into strains, each differing greatly in virulence and other properties. For example, two virus strains, chemically distinct, may produce indistinguishable symptoms in one orchid plant but strikingly different symptoms in another. Diseases caused by unrelated viruses may resemble one another more closely than diseases caused by strains of the same virus. Certain variegated plants, such as *Abutilon* and Rembrandt tulips, owe their horticultural uniqueness and desirability to being inherently virus-infected.

Transmission. With the exception of tobacco mosaic virus, relatively few viruses or viroids are spread extensively in the field by contact between diseased and healthy leaves.

All viruses that spread within their host tissues (systemically) can be transmitted by grafting branches or buds from diseased plants on healthy plants. Natural grafting and transmission are possible by root grafts and with dodder (*Cuscuta* species). Vegetative propagation often spreads plant viruses. Fifty to 60 viruses are transmitted in seed, and a few seed-borne viruses, such as sour-cherry yellows, are carried in pollen and transmitted by insects.

Most disease-causing viruses are carried and transmitted naturally by insects and mites, which are called vectors of the virus. The principal virus-carrying insects are about 200 species of aphids, which transmit mostly mosaic viruses, and more than 100 species of leafhoppers, which carry yellows-type viruses. Whiteflies, thrips, mealybugs, plant hoppers, grasshoppers, scales, and a few beetles also serve as vectors for certain viruses. Some viruses may persist for weeks or months and even duplicate themselves in their insect vectors; others are carried for less than an hour. Slugs, snails, birds, rabbits, and dogs also transmit a few viruses, but this is not common.

A small number of plant viruses are soilborne. Viruses causing grape fanleaf, tobacco rattle, and tobacco and tomato ring spots, as well as several strawberry viruses, are spread by nematodes feeding externally (*i.e.,* ectoparasitic) on plant roots. A few soilborne viruses may be spread by the swimming spores of primitive, soil-inhabiting pathogenic fungi, such as those causing big vein of lettuce, soilborne wheat mosaic, and tobacco necrosis.

Viruses often overwinter in biennial and perennial crops and weeds (plants that overwinter by means of roots and produce seed in their second year or during several years, respectively), in plant debris, and in insect vectors. Plants, once infected, normally remain so for life.

Control. After a plant is infected with a virus/viroid, little can be done to restore its health. Control is accomplished by several methods, such as growing resistant species and varieties of plants or obtaining virus-free seed, cuttings, or plants as a result of indexing and certification programs. Indexing is a procedure to determine the presence or absence of viruses not readily transmitted mechanically. Material from a "test" plant is grafted to an "indicator" plant that develops characteristic symptoms if affected by the viral disease in question. In addition, more drastic measures are sometimes followed, including destroying (roguing) infected crop and weed host plants and enforcing state and national quarantines or embargoes. Further control measures include controlling insect vectors by spraying plants with contact insecticides or fumigating soil to kill insects, nematodes, and other possible vectors. Growing valuable plants under fine cheesecloth or wire screening that excludes insect vectors also is done. Separation of new from virus-infected plantings of the same or closely related species is sometimes effective, and the simple practice of not propagating from plants suspected or known to harbour a virus also reduces loss.

Temperature treatments for virus control

Infected peach, apple, and rose budwood stock and carnations have been grown for weeks or months at temperatures about 37° to 38° C (99° to 100° F) to free new growth from viruses. Soaking some woody plant parts or virus-infected sugarcane shoots in hot water at about 50° C (120° F) for short periods also is effective. Both dry and wet heat treatments are based on the sensitivity of certain viruses to high temperatures. Rapidly growing dahlia and chrysanthemum sprouts outgrow viruses so that stem tips can be used to propagate healthy plants. With certain carnations, chrysanthemums, and potatoes, a few cells from the growing tip have been grown under sterile conditions in tissue culture; from these, whole plants have been developed free from viruses.

Examples of virus and viroid diseases are characterized in Table 14.

Diseases caused by bacteria. Thousands of bacterial species occur in nature. Many of these perform biochemical processes essential for the continuity of life; for example, bacterial detritivores, or decomposers, feed on nonliving organic matter, recycling it through the ecosys-

tem. There are, however, hundreds of bacterial species that cause diseases in humans, animals, and plants. For examples of diseases caused by bacteria, see Figure 3.

General characteristics. Bacteria are prokaryotic microorganisms—*i.e.*, single-celled microorganisms in which the nuclear substance is not enclosed in a membrane (see also BACTERIA). There are two major types of bacteria, the eubacteria and the archaebacteria, and they are distinguished by differences in the composition of their cell wall and cytoplasmic membrane and by certain metabolic features. Plant pathogens belong to the eubacteria. The eubacteria can be divided into three groups: gram-negative bacteria, gram-positive bacteria, and the mycoplasmas and spiroplasmas, referred to as mycoplasma-like organisms (MLOs). Gram-negative and gram-positive bacteria are distinguished on the basis of their cell wall structure, which affects the ability of the bacterium to react to the Gram stain—one of the most useful stains in bacteriologic laboratories. The distinguishing characteristic of MLOs is their lack of a cell wall; their outer boundary is instead a cytoplasmic membrane, which imparts some unusual properties not found in most eubacteria. MLOs belong to the taxonomic class Mollicutes. Plant diseases caused by MLOs are grouped as agents of "decline" (characterized by loss of vigour, decrease in yield of fruit, and eventual death) and agents of virescence (the greening of flowers) and developmental abnormalities.

The principal genera of plant pathogenic bacteria are *Agrobacterium, Clavibacter, Erwinia, Pseudomonas, Xanthomonas, Streptomyces,* and *Xylella.* With the exception of *Streptomyces* species, all are small, single, rod-shaped cells approximately 0.5 to 1.0 micrometre (0.00002 to 0.00004 inch) in width and 1.0 to 3.5 micrometres in length. Streptomycetes develop branched mycelia (narrow, threadlike growth) with curled chains of conidia (spores) on the tips of the mycelia. *Streptomyces* are gram-positive; most species of the other genera are gram-negative.

Symptoms and signs. Bacterial diseases can be grouped into four broad categories based on the extent of damage to plant tissue and the symptoms that they cause, which may include vascular wilt, necrosis, soft rot, and tumours. Vascular wilt results from the bacterial invasion of the plant's vascular system. The subsequent multiplication and blockage prevents movement (translocation) of water and nutrients through the xylem of the host plant. Drooping, wilting, or death of the aerial plant structure may occur; examples include bacterial wilt of sweet corn, alfalfa, tobacco, tomato, and cucurbits (*e.g.*, squash, pumpkin, and cucumber) and black rot of crucifers. Pathogens can cause necrosis by secreting a toxin (poison). Symptoms include formation of leaf spots, stem blights, or cankers. Soft rot diseases are caused by pathogens that secrete enzymes capable of decomposing cell wall structures, thereby destroying the texture of plant tissue—*i.e.*, the plant tissue becomes macerated (soft and watery). Soft rots commonly occur on fleshy vegetables such as potato, carrot, eggplant, squash, and tomato. Tumour diseases are caused

Table 14: Some Viral and Viroid Diseases of Plants

disease	causative agent	hosts	symptoms and signs	additional features
Tobacco mosaic	tobacco mosaic virus (TMV)	tobacco, tomato, and hundreds of other vegetables and weeds	mottled appearance of leaves (mosaic pattern); dwarfing	virus remains viable for years in soil and tobacco; the disease occurs worldwide; significant economic losses can occur
Cucumber mosaic	cucumber mosaic virus (CMV)	cucumber, bean, tobacco, and other plants (wide range of hosts)	similar to those of TMV infections	worldwide occurrence; very broad range of hosts
Barley yellow dwarf	barley yellow dwarf virus (BYDV)	barley, oats, rye, wheat; also pasture grasses and weeds	yellowing and dwarfing of leaves; stunting of plants	one of the most important diseases of small grains
Tomato spotted wilt	tomato spotted wilt virus (TSWV)	tomato, pepper, pineapple, peanut, and many other plants	leaves show concentric, necrotic rings; necrotic region yellow, then turning red-brown	very wide host range; infects hundreds of different plants
Prunus necrotic ring spot	prunus necrotic ring spot virus (PNRV)	stone fruits—*e.g.*, cherry, almond, peach, apricot, plum, and others	delayed foliation; leaves on infected branches show light green spots and dark rings, then become necrotic and fall off	very widespread disease of stone fruits; affects almost all trees in fruit-producing regions
Potato spindle tuber	potato spindle tuber viroid (PSTV)	potato and tomato	stunted growth; tubers are spindle-shaped and smaller than healthy tubers	the first identified viroid infection in plants; can cause major reduction in crop yield
Citrus exocortis	citrus exocortis viroid (CEV)	orange, lemon, lime, and other citrus plants	infected trees show vertical splits in bark, thin strips of partially loosened bark, and a cracked, scaly appearance	worldwide distribution; causes reduction of crop yield

by bacteria that stimulate uncontrolled multiplication of plant cells, resulting in the formation of abnormally large structures.

Most bacteria produce one major symptom; a few produce a range or combination of symptoms such as those shown in Table 12. In general, it is not particularly difficult to tell whether a plant is affected by a bacterial pathogen; however, identification of the causative agent at the species level requires isolation and characterization of the pathogen using numerous laboratory techniques (see above *Technological advances in the identification of pathogenic agents*).

Transmission and infection. In order for a bacterium to produce a disease in a plant, the bacterium must first invade the plant tissue and multiply. Bacterial pathogens enter plants through wounds, principally produced by adverse weather conditions, humans, tools and machinery, insects, and nematodes, or through natural openings such as stomates, lenticels, hydathodes, nectar-producing glands, and leaf scars.

Most foliage invaders are spread from plant to plant by windblown rain or dust. Humans disseminate bacteria through cultivation, grafting, pruning, and transporting diseased plant material. Animals, including insects and mites, are other common transmission agents. Some bacteria, such as the causal agent of Stewart's, or bacterial, wilt of corn (*Erwinia stewartii*), not only are spread by a flea beetle but also survive over winter in this insect.

Bacterial dormancy

When conditions are unfavourable for growth and multiplication, bacteria remain dormant on or inside plant tissue. Some, such as the crown gall bacterium, may survive for months or years in the soil.

Bacterial diseases are influenced greatly by temperature and moisture. Often, a difference of only a few degrees in temperature determines whether a bacterial disease will develop. In most cases, moisture as a water film on plant surfaces is essential for establishing an infection.

Control. In general, the diseases caused by bacteria are relatively difficult to control. This is partly attributable to the speed of invasion as bacteria enter natural openings or wounds directly. Direct introduction also enables them to escape the toxic effects of chemical protectants. Losses from bacterial diseases are reduced by the use of pathogen-free seed grown in arid regions. Examples of diseases controlled by this method include bacterial blights of beans and peas, black rot of crucifers, and bacterial spot and canker of tomato. Seed treatment with hot water at about 50° C (120° F) is also effective for crucifers, cucurbits, carrot, eggplant, pepper, and tomato. Bactericidal seed compounds control some bacterial diseases, such as angular leaf spot of cotton, gladiolus scab, and soft rot of ornamentals. Rotation with nonhost crops reduces losses caused by wilt of alfalfa, blights of beans and peas, black rot of crucifers, crown gall, and bacterial spot and canker of tomato. Eradication and exclusion of host plants has been useful against citrus canker, angular leaf spot of cotton, fire blight, and crown gall. Resistant varieties of crop plants have been developed to reduce losses from wilts of alfalfa, corn, and tobacco; angular leaf spot of cotton and tobacco; and bacterial pustule of soybeans, among others. Protective insecticidal sprays help control bacterial diseases, such as wilts of sweet corn and cucurbits and soft rot of iris. Protective bactericidal sprays, paints, or drenches containing copper or antibiotics are used against bacterial blights of beans and celery, fire blight, crown gall, blackleg of delphinium, and filbert and walnut blights. Finally, sanitary measures—*i.e.*, clean plow down of crop refuse, destruction of volunteer plants and weeds, sterilization of pruning and grafting tools—as well as refraining from cultivating when foliage is wet, overhead watering and spraying of indoor plants, and late cutting or grazing of alfalfa and other crops, are useful in reducing the incidence of bacterial diseases.

The characteristics of several plant diseases caused by bacteria are summarized in Table 15.

Diseases caused by fungi. Fungi cause the great majority, an estimated two-thirds, of infectious plant diseases. They include all white and true rusts, smuts, needle casts, leaf curls, mildew, sooty molds, and anthracnoses; most leaf, fruit, and flower spots; cankers; blights; scabs, root, stem, fruit, and wood rots; wilts; leaf, shoot, and bud galls; and many others. For examples of diseases caused by fungi, see Figure 4. All economically important plants apparently are attacked by one or more fungi; often many different fungi may cause disease in one plant species.

General characteristics. The fungi represent an extremely large and diverse group of eukaryotic microorganisms (see also FUNGI). The cells, which contain a membrane-bound nucleus, are devoid of chlorophyll and have rigid cell walls. Fungi have a plantlike vegetative body consisting of microscopic branching threadlike filaments of various lengths, called hyphae (singular hypha), some of which extend into the air while others penetrate the substrate on which they grow. The hyphae are arranged into a network called a mycelium. It is the mass of the mycelium that gives fungal growth its characteristic "cot-

Table 15: Some Bacterial Diseases of Plants

disease	causative agent	hosts	symptoms and signs	additional features
Granville wilt	*Pseudomonas solanacearum*	tobacco, tomato, potato, eggplant, pepper, and other plants	stunting, yellowing, and wilting of parts above ground; roots decay and become black or brown	occurs in most countries in temperate and semitropical zones; causes crop losses of hundreds of millions of dollars
Fire blight	*Erwinia amylovora*	apple and pear	blossoms appear water-soaked and shrivel, spreads to leaves and stems, causing rapid dieback	first plant disease proved to be caused by a bacterium
Wildfire of tobacco	*Pseudomonas syringae*	tobacco	yellowish green spots on leaves	wildfire of tobacco occurs worldwide—causes losses in seedlings and field plants
Blight of beans	*Xanthomonas campestris*	beans (common blight)	yellowish green spots on leaves	most phytopathogenic xanthomonads and pseudomonads cause necrotic spots on green parts of susceptible hosts; may be localized or systemic
	Pseudomonas syringae	beans (brown spot)	small water-soaked spots on lower side of leaves enlarge, coalesce, and become necrotic	
Soft rot	*Erwinia carotovora*	many fleshy-tissue fruits—*e.g.*, cabbage, carrot, celery, onion	soft decay of fleshy tissues that become mushy and soft	occurs worldwide; causes major economic losses
Crown gall	*Agrobacterium tumefaciens*	more than 100 genera of woody and herbaceous plants	initially a small enlargement of stems or roots usually at or near the soil line, increasing in size, becoming wrinkled, and turning brown to black	the conversion of a normal cell to one that produces excessive cell multiplication is caused by a plasmid (a small circular piece of DNA) carried by the pathogenic bacterium
Aster yellows	Mycoplasma-like organism (MLO)	many vegetables, ornamentals, and weeds	chlorosis; dwarfing malformations	greatest losses suffered by carrots; transmission by leafhoppers
Citrus stubborn disease	*Spiroplasma citri* (MLO)	citrus and stone fruits and vegetables	chlorosis, yellowing of leaves, shortened internodes, wilting	first MLO pathogen of plant disease cultured

Figure 4: *Plant diseases caused by fungi.*

tony" or "fuzzy" appearance. Fungi reproduce by a variety of methods, both asexual and sexual. They produce many kinds of spores in very large numbers. For example, the colour of a moldy piece of bread is due to the colour of a massive number of microscopic mold spores.

Symptoms and signs. In general, a fungal infection can cause local or extensive necrosis. It can also inhibit normal growth (hypotrophy) or induce excessive abnormal growth (hypertrophy or hyperplasia) in a portion of or throughout an entire plant. Symptoms associated with necrosis include leaf spots, blight, scab, rots, damping-off, anthracnose, dieback, and canker. Symptoms associated with hyperplasia include clubroot, galls, warts, and leaf curls (see Table 12).

In some instances, the fungus infecting the plant may produce growth or structures on the plant, stems, or leaves such as masses of mycelium or aggregates of spores with a characteristic appearance. These developments are referred to as signs of infection, in contrast to symptoms, which refer specifically to the plant or plant tissue (see Table 13).

Transmission. Fungi are spread primarily by spores, which are produced in abundance. The spores can be carried and disseminated by wind currents, water (splashing and rain), soil (dust), insects, birds, and the remains of plants that once were infected. Vegetative fungal cells that exist in dead plant material also can be transmitted when they come in contact with a susceptible host. The survival of vegetative cells of plant pathogenic fungi in nature depends on climatic conditions, particularly temperature and moisture. Vegetative cells can survive temperatures from −5° to 45° C (23° to 113° F); fungal spores are considerably more resistant. The germination of spores, however, is favoured by mild temperatures and high humidity.

Control. Because many thousands of fungal species can infect a broad range of plants and because each fungal species has different characteristics, a variety of practices are available to control fungal diseases. The principal control measures include the use of disease-free seed and propagating stock, the destruction of all plant materials that may harbour pathogenic fungi, crop rotation, the development and use of resistant plant varieties, and the use of chemical and biological fungicides.

Several fungal diseases are characterized in Table 16.

Diseases caused by nematodes. Nematodes parasitic on plants are active, slender, unsegmented roundworms (also called nemas or eelworms). The great majority cannot be seen with the unaided eye, because they are very small and translucent. Practically all adult forms fall within the range of 0.25 to 2 millimetres in length. About 1,200 species cause disease in plants. Probably every form of plant life is fed upon by at least one species of nematode. They usually live in soil and attack small roots, but some species inhabit and feed in bulbs, buds, stems, leaves, or flowers. For examples of diseases caused by nematodes, see Figure 5.

Mode of nematode attack. Nematodes parasitic on plants obtain food by sucking juices from them. Feeding is accomplished through a hollow, needlelike mouthpart called a spear or stylet. The nematode pushes the stylet into plant cells and injects a liquid containing enzymes, which digest plant cell contents. The liquefied contents are then sucked back into the nematode's digestive tract through the stylet. Nematode feeding lowers natural resistance, reduces vigour and yield of plants, and affords easy entrance for wilt-producing or root rot-producing fungi or bacteria and other nematodes. Nematode-infested plants are weak and often appear to suffer from drought, excessive soil moisture, sunburn or frost, a mineral deficiency or imbalance, insect injury to roots or stems, or disease.

Symptoms of nematode injury

Common symptoms of nematode injury include stunting, loss of green colour and yellowing; dieback of twigs and shoots; slow general decline; wilting on hot, bright days; and lack of response to water and fertilizer. Feeder root systems are reduced; they may be stubby or excessively branched, often discoloured, and decayed. Winterkill of orchard trees, raspberries, strawberries, ornamentals, and

Table 16: Some Fungal Diseases of Plants

disease	causative agent	hosts	symptoms and signs	additional features
Late blight of potato	*Phytophthora infestans*	potato	water-soaked dark green to black or purplish lesions with pale green margins on lower leaves, white mildew at edge of lesions	responsible for Irish famine; caused starvation and death and mass migration of population
Chestnut blight	*Endothia parasitica*	chestnut tree	yellowish to reddish brown patches appear on bark; lesions spread quickly and girdle twigs or limbs, which die	disease accidently imported from Asia; first observed in New York in 1904 and rapidly spread across the United States, practically eliminating native American chestnuts
Dutch elm disease	*Ceratocystis ulmi*	elm tree	leaves wilt, turn dull green to yellow or brown, and drop off; branches die	the causative fungus is believed to have entered Europe from Asia during World War I and was later transported to the United States (1930) on elm burl logs imported for furniture veneer; elm bark beetles spread the pathogen in the United States
Black stem rust of wheat	*Puccinia graminis*	wheat; many grasses	on wheat, rust-coloured pustules with spores, chlorosis of surrounding tissue, followed by development of black teliospores; on barberry, chlorosis and hypertrophy of infected tissue, orange spore masses	disease occurs wherever wheat is grown; in 1935 it destroyed about 60 percent of the total hard red spring wheat crop in Minnesota and South Dakota; fungus has a complex life cycle, partly on wheat and partly on the barberry plant; eradication of the barberry plant is an important control measure
Coffee rust	*Hemileia vastatrix*	coffee	orange-yellow powdery spots on lower side of leaves; centres turn brown and leaves fall	most destructive disease of coffee; has caused devastating losses in all coffee-producing countries
White-pine blister rust	*Cronartium ribicola*	white pine tree	small, discoloured, spindle-shaped cankers surrounded by narrow band of yellow-orange bark; blisters exude secretion followed by bright orange pustules	one of the most important forest diseases in the United States; currant is the alternate host, and its eradication is an important control measure
Corn smut	*Ustilago maydis*	corn	minute galls form on young corn seedlings; on older plants, large galls are produced on the silk of ears and on tassels, leaves, and stalks	occurs wherever corn is grown; may cause serious crop damage
Loose smut	*Ustilago nuda*	barley, oats, wheat	infected heads are covered with masses of olive-green spores	worldwide occurrence; destroys kernels of the infected plant
Downy mildew	many species of the family Peronosporaceae	many types of plants: grapes, grasses, vegetables, and others	yellow irregular spots appear on upper leaf surface; downy fungus growth appears on underside; leaves die	one of the first plant diseases controlled by a fungicide—*i.e.,* Bordeaux mixture, a mixture of lime and copper sulfate used on grapes
Powdery mildew	many species of the family Erysiphaceae	many types of plants: grasses, vegetables, shrubs, and trees	spots of powdery mildew growth that enlarge to cover leaves or other plant organs	one of the most common and widely spread plant diseases
Apple scab	*Venturia inaequalis*	apple	small olive-coloured areas appear on young leaves, later turn black, and may coalesce; black circular spots appear on fruit	occurs almost everywhere apples are grown; infection reduces fruit size and quality
Black spot of rose	*Diplocarpon rosae*	rose	large circular black lesions on leaves; leaves turn yellow and fall off	classified as an anthracnose, which affects leaves, stems, and fruits of many plants
Anthracnose of grape	*Elsinae ampelina*	grape	(as above)	(as above)
Nectria canker	*Nectria galligena*	apple and pear and many hardwood forest trees	initially small circular brown areas that enlarge and become depressed with raised edges; callus tissue produced around canker	one of the most important diseases of pear, apple, and hardwood forest trees
Black knot of plum and cherry	*Plowrightia morbosum*	plum and cherry	small black knotty swellings on twigs and branches	occurs primarily in the eastern half of the United States and New Zealand
Brown rot	*Monilinia fructicola*	stone fruits	brown spots on blossoms; twigs develop small sunken brown cankers; fruit develops brown spots that spread rapidly	worldwide occurrence; can cause heavy losses both in orchards and in shipment
Soft rot	*Rhizopus* species	flowers, fruits, and vegetables with fleshy organs	tissues become soft with water-soaked appearance that often spreads rapidly, followed by development of fuzzy gray mycelium and black spores	infection develops most rapidly on ripe fruits with favourable conditions (moderate temperature and high humidity)
Fusarium wilt of tomato	*Fusarium oxysporum*	tomatoes	leaves are bent down, growth is stunted, plant dies; dark streaks appear in vascular tissue	one of the most destructive diseases of tomato; entire fields can be destroyed
Wilts of vegetables, flowers, and some trees	*Verticillium* species	cotton, potato, tomato, alfalfa, shade trees, and others	similar to fusarium wilts; develops primarily in seedlings that die shortly after infection; older plants also are attacked	worldwide distribution; the fungus infects hundreds of species of plants

other perennials is commonly associated with nematode infestations.

Root injury develops partly from the nematodes feeding on cells and partly from toxic salivary excretions of the parasite. Tissues often respond by producing either an enlargement or degeneration of cells; sometimes both occur.

Many nematodes are native and attack cultivated plants when their natural hosts are removed. Others have been introduced with seedling plants, bulbs, tubers, and particularly in soil balled around roots of infested nursery stock.

Nematodes may live part of the time free in soil around roots or in fallow gardens and fields. They tunnel inside plant tissues (endoparasites) or feed externally from the surface (ectoparasites) and may enter a plant through wounds or natural openings or by penetrating roots. All nematodes parasitic on plants require living plant tissues for reproduction. Nematodes are attracted to host roots by sensing either the heat given off by roots or the chemicals secreted by roots.

Most species require 20 to 60 days to complete a generation from egg through four larval stages to adult and back to egg. Some nematodes have only one generation a year but still produce several hundred offspring.

Soil populations and developmental rate of nematodes are affected by the length of the growing season; temperature; availability of water and nutrients; and moisture, type, texture, and structure of soil. Also important are populations of nematode-parasitic bacteria, viruses, some 50 different nematode-trapping fungi, protozoans, mites, flatworms, or other pests, and other nematodes. Toxic chemicals added to the soil or those secreted by plant roots; crop rotations and past cropping history; species, variety, age and nutrition of growing plants; and other factors are additional conditions that affect nematode populations.

Certain species live strictly in light, sandy soils; some build up high populations in muck soils; and a few seem to thrive in heavy soils. High populations and greater crop damage are much more common in light sandy soils than in heavy clay soils.

Many plant-infecting nematodes become inactive at temperatures between 5° and 15° C (41° and 59° F) and 30° and 40° C (86° and 104° F). The optimum for most is 20° to 30° C (68° to 86° F), but this varies greatly with the species, stage of development, activity, growth of the host, and other factors.

Numbers of nematodes in diseased plants

Nematodes may be found in plant tissues in large numbers. Hundreds of thousands may be present in infested roots or bulbs.

After a plant-infecting nematode has been accidentally introduced into a garden or field, several years pass before the population builds up sufficiently (*i.e.*, up to several billion or more active nematodes per hectare) to cause conspicuous symptoms in a large number of plants. This is because nematodes move very slowly through soil—rarely more than 75 centimetres a year. Nematodes are easily spread, however, by moving infested soil, plant parts, or contaminated objects—*e.g.*, tools and machinery, bags and other containers, running water, wind, clothing, shoes, animals, birds, and infested planting stock.

Root-knot nematodes

Nematode diseases. Root-knot nematodes (*Meloidogyne* species) are well known because of the conspicuous "knots," or gall-like swellings, they induce on roots. More than 2,000 kinds of higher plants are subject to their attack. Losses are often heavy, especially in warm regions with long growing seasons. Certain species, however, such as the northern root-knot nematode (*M. hapla*), are found where soil may freeze to depths of nearly a metre. Vegetables, cotton, strawberry, and orchard trees are commonly attacked. Garden plants and ornamentals frequently become infested through nursery stock.

Root-lesion nematodes (*Pratylenchus* species), cosmopolitan in distribution, are endoparasites that cause severe losses to hundreds of different crop and ornamental plants by penetrating roots and making their way through the tissues, breaking down the cells as they feed. They deposit eggs from which new colonies develop. After a root begins to decline in vigour, nematodes move into the soil in search of healthy roots. Lesions form in the root as fungi and bacteria enter damaged tissues, and root rot often occurs. Annual crops may succumb early in the season, but perennials and orchard trees may not decline for several years.

Figure 5: *Plant diseases caused by nematodes.*
(Left) Aboveground symptoms on potato plants infested by the golden nematode of potatoes and a secondary fungal infection. (Right) "Knots" on root of sugar beet caused by root-knot nematodes.
(Left and right) © Nigel Cattlin/Holt Studios International—Photo Researchers, Inc

The golden nematode of potatoes (*Heterodera rostochiensis*) is a menace of the European potato industry. Great efforts have been made to control it. The speck-sized golden cysts that dot infested plant roots are the remains of female bodies. Each cyst may contain up to 500 eggs, which hatch in the soil over a period of up to 17 years. A chemical given off by potato and tomato roots stimulates hatching of the eggs.

A related, cyst-forming species, the sugar beet nematode (*H. schachtii*), is a pest that has restricted acreage of sugar beets in Europe, Asia, and America.

The citrus nematode (*Tylenchulus semipenetrans*) occurs wherever citrus is grown, exacting a heavy toll in fruit quality and production. Typical symptoms are a slow decline, yellowing and dying of leaves, and dieback of twigs and branches in many groves 15 years or older. Infested nursery stock has widely distributed the nematode. The burrowing nematode (*Radopholus similis*) is a serious endoparasite in tropical and subtropical areas, where it attacks citrus (causing spreading decline), banana, avocado, tomato, black pepper, abaca, and more than 200 important crops, trees, and ornamentals, causing severe losses.

Root-feeding nematodes

Many important ectoparasites feed on plant roots—dagger nematodes (*Xiphinema*), stubby-root nematodes (*Trichodorus*), spiral nematodes (*Rotylenchus* and *Helicotylenchus*), sting nematodes (*Belonolaimus*), and pin nematodes (*Paratylenchus*). Leaf, or foliar, nematodes (*Aphelenchoides* species) and bulb and stem nematodes (*Ditylenchus dipsaci*) cause severe losses in vegetable and ornamental bulb crops, clovers, alfalfa, strawberry, sweet potato, orchids, chrysanthemums, begonias, and ferns.

Control measures. Control measures for nematodes often include rotation with nonhost plants, growing of resistant varieties and species, use of certified, nematode-free nursery stock, and use of soil fumigants (nematicides) as preplanting or postplanting treatments. Steam or dry heat is applied to soil in confined areas, such as greenhouse benches and ground beds. Exposure to moist heat, such as steam or hot water at 50° C (120° F) for 30 minutes, is sufficient to kill most nematodes and nematode eggs. Shorter periods are needed at higher temperatures. State and federal quarantines prohibiting movement of infested soil, plants or plant parts, machinery, and other likely carriers also exist. Cultural practices to promote vigorous plant growth (*i.e.*, watering during droughts, proper application of fertilizers, clean cultivation, fall and summer fallowing, use of heavy organic mulches or cover crops, and plowing out roots of susceptible plants after harvest) are useful for specific nematodes. Asparagus, marigolds (*Tagetes* species), and *Crotalaria* species are toxic to many plant-infecting nematodes.

Parasitic seed plants. A number of flowering plants are parasites of other plants. Among the more important ones are mistletoe, dodder, and witchweed. For an example of diseases caused by parasitic plants, see Figure 6.

Figure 6: Dodder, a seed-producing parasite, entwined around blueberry.
Courtesy of Dr. W.V. Welker, weed scientist, USDA (retired)

Mistletoe. Mistletoes are semiparasitic seed plants that feed on trees and obtain water and mineral salts by sending rootlike structures (haustoria) into vascular tissue of the inner bark. There are three important types: American (*Phorodendron* species), European (*Viscum album*), and dwarf (*Arceuthobium* species). All produce sticky seeds spread by birds. American mistletoe, restricted to the Americas, is best known for its ornamental and sentimental uses at Christmastime. The leafy, bushy evergreen masses, up to one metre or more in diameter, appear on tree branches. They are most conspicuous after deciduous leaves have fallen. The European mistletoe is similar in habit and appearance to its American relative. Tree branches infected by mistletoes may become stunted or even die.

Dwarf mistletoe

Dwarf mistletoe is common on and very destructive to conifers in forests. Seedlings and young trees may be stunted, deformed, or killed. Conspicuous witches'-brooms form in the crown or spindle-shaped swellings (later cankers) in limbs and trunk. Canker and wood-rotting fungi often enter through mistletoe wounds. Dwarf mistletoes frequently escape detection because the scaly-leaved plants may be less than 2½ centimetres long; they do range to 30 to 45 centimetres, however. Dwarf mistletoes occur scattered along conifer limbs and small branches. After the mistletoe has grown internally for about a year, the branch may start to form a witches'-broom. Four to five years elapse before the yellow to brown to olive-green shoots form fruits. The sticky seeds are shot with explosive force from the fruit for horizontal distances ranging from 5 to more than 18 metres; this is one of the most remarkable methods for seed discharge among plants. Once seeds adhere to a branch, they germinate on young bark and penetrate into the host tree's vascular system. Control for mistletoes in individual trees involves removal of infected branches a foot or more beyond any evidence of the parasite before the fruits ripen.

Dodder. More than 100 species of dodder (*Cuscuta*) are widely distributed and called such names as strangleweed, devil's-hair, pull down, hell-bind, love vine, and goldthread. The leafless, yellow-orange, threadlike stems twine around a number of field and garden host plants. By extending to nearby plants, it may draw them together and downward until a tangled yellowish orange patch is formed. The infested area is usually less than three metres across the first year; it spreads more rapidly in succeeding years. Dodder is widely distributed as a contaminant with field seed; hence the losses in clover, alfalfa, and flax fields. Dodder is controlled by planting certified, properly cleaned seed and by mowing patches of dodder in the field well before the seeds form. The dried patches are sprinkled with fuel oil and burned. Careful application of selective herbicides or a soil fumigant and sowing heavily infested areas with resistant plants (*e.g.*, garden beans, soybean, corn, cowpea, pea, grasses, or small grains) are also control methods.

Witchweed. Witchweed, a small parasitic weed (*Striga asiatica*), is widely distributed in Asia, southern Africa, and the Sahel. It has been known in the coastal sandy soils of North and South Carolina since the mid-1950s but through intensive efforts has been contained. Witchweed parasitizes the roots of many hosts, including maize (corn), sorghum, sugarcane, rice, small grains, and more than 50 species in the grass and sedge families. A serious infestation may cause corn plants to be severely stunted, wilt, and turn yellow or brown, thus reducing the acre yield. *Striga* plants, which rarely exceed heights of 20 to 25 centimetres, have small, red, yellowish red, yellow, or white flowers. One plant may produce hundreds of thousands of tiny brown seeds that can remain alive in soil for years until stimulated to germinate by a secretion from a nearby host root. Witchweed robs the host of water and food, causing it to grow more slowly than normal and often to die before maturing. Control is difficult; useful measures include application of selective herbicides before seeds are produced; rotation with a resistant crop and keeping plantings free of weed grasses that may serve as hosts; and prevention of seed set by growing trap crops and then destroying them with herbicides.

Control of witchweed

BIBLIOGRAPHY

General works. LAWRIE REZNEK, *The Nature of Disease* (1987), written for the general reader, discusses the nature of disease from several perspectives, including medical, legal, political, philosophical, and economic. DAVID O. SLAUSON, BARRY J. COOPER, and MAJA M. SUTER, *Mechanisms of Disease: A Textbook of Comparative General Pathology,* 2nd ed. (1990), written for the veterinary student but a great resource for pathologists and biomedical researchers, provides a fundamental overview of the mechanisms of diseases, often at the molecular level. MAX SAMTER (ed.), *Immunological Diseases,* 4th ed., 2 vol. (1988), covers the collagen diseases. F.M. BURNET, *The Natural History of Infectious Disease,* 3rd ed. (1962), offers a unique view of infectious disease as an ecological and evolutionary phenomenon. Books for the general reader include JUNE GOODFIELD, *Quest for the Killers* (1985), exploring efforts to conquer several epidemic diseases; ANDREW SCOTT, *Pirates of the Cell: The Story of Viruses from Molecule to Microbe,* rev. ed. (1987); and PETER RADETSKY, *The Invisible Invaders: The Story of the Emerging Age of Viruses* (1991). (W.Bu./D.G.Sc.)

Human disease. KENNETH F. KIPLE (ed.), *The Cambridge World History of Human Disease* (1993), a reference text written for advanced undergraduates and professionals in the biomedical and social sciences, surveys the medical and geographic characteristics of human diseases worldwide throughout history. JAMES B. WYNGAARDEN, LLOYD H. SMITH, JR., and J. CLAUDE BENNETT (eds.), *Cecil Textbook of Medicine,* 19th ed. (1992), considers all facets of human disease in depth from the modern point of view. *Goodman & Gilman's The Pharmacological Basis of Therapeutics,* 9th ed. by JOEL G. HARDMAN and LEE E. LIMBIRD (1996), is a comprehensive text on drugs. T.R. HARRISON, *Harrison's Principles of Internal Medicine,* 13th ed. edited by KURT J. ISSELBACHER *et al.* (1994), discusses in detail the cardinal manifestations of disease under various headings. THEODORE LIDZ, *The Person: His and Her Development Throughout the Life Cycle,* rev. ed. (1976, reissued 1983), provides an excellent insight into humans, the psychological organisms. VINAY KUMAR, RAMZI S. COTRAN, and STANLEY L. ROBBINS, *Basic Pathology,* 5th ed. (1992), clearly and succinctly presents the causes and pathogenesis of human disease with an emphasis on molecular mechanisms. MARGARET W. THOMPSON, RODERICK R. MCINNES, and HUNTINGTON F. WILLARD, *Thompson & Thompson Genetics in Medicine,* 5th ed. (1991), is a well-illustrated and clearly written text on basic genetic principles and their relation to the genesis of human disease. CHARLES R. SCRIVER *et al.* (eds.), *The Metabolic Basis of Inherited Disease,* 6th ed., 2 vol. (1989), a monumental, highly technical text, provides a comprehensive presentation of the clinical, biochemical, and genetic information concerning those diseases thought to be a consequence of genetic variation. More specific in focus and perhaps less monumental (if not less technical) than the above are ROGER N. ROSENBERG *et al.* (eds.), *The Molecular and Genetic Basis of Neurological Disease* (1993); ALDONS J. LUSIS, JEROME I. ROTTER, and ROBERT S. SPARKES (eds.), *Molecular Genetics of Coronary Artery Disease* (1992); and LINDA L. GALLO (ed.), *Cardiovascular Disease: Molecular and Cellular Mechanisms, Prevention, and Treatment* (1987), which address their particular topics on cellular and molecular levels. ROBERT C. GALLO and FLOSSIE WONG-STAAL (eds.), *Retrovirus Biology and Human Disease* (1990), written for the technically advanced reader, covers various topics in retrovirology, including historical background, epidemiology, clinical features, molecular

biology, immunology, and therapeutic approaches. ADRIANNE BENDICH and C.E. BUTTERWORTH, JR. (eds.), *Micronutrients in Health and in Disease Prevention* (1991), discusses evidence of a correlation between the intake of nonoptimal levels of dietary micronutrients and the development of chronic diseases; although written for the health-care professional, it is also valuable to anyone interested in the relationship between nutrition and health. (S.L.R./J.H.Ro./D.G.Sc.)

Diseases of animals. CALVIN W. SCHWABE, *Veterinary Medicine and Human Health,* 3rd ed. (1984), provides a comprehensive reference on medical public health. Also of interest is PAUL R. SCHNURRENBERGER, ROBERT S. SHARMAN, and GILBERT H. WISE, *Attacking Animal Diseases: Concepts and Strategies for Control and Eradication* (1987). J.F. SMITHCORS, *Evolution of the Veterinary Art: A Narrative Account to 1850* (1957), comprehensively treats veterinary medical history and the history of the knowledge of animal diseases; it is brought up to date by D.H.V. STALHEIM, *The Winning of Animal Health: 100 Years of Veterinary Medicine* (1994). LISE WILKINSON, *Animals and Disease: An Introduction to the History of Comparative Medicine* (1992), studies the interrelation of animal and human diseases. O.M. RADOSTITS, D.C. BLOOD, and C.C. GAY, *Veterinary Medicine,* 8th ed. (1994), focuses on livestock. CARLTON L. GYLES and CHARLES O. THOEN (eds.), *Pathogenesis of Bacterial Infections in Animals* (1986); JOHN W. DAVIS, LARS H. KARSTAD, and DANIEL O. TRAINER (eds.), *Infectious Diseases of Wild Mammals,* 2nd ed. (1981); and IVAL ARTHUR MERCHANT and RALPH DAVID BARNER, *An Outline of the Infectious Diseases of Domestic Animals,* 3rd ed. (1964), are textbooks about animal diseases. GEORGE F. BODDIE, *Diagnostic Methods in Veterinary Medicine,* 6th ed. (1969); JIRO J. KANEKO (ed.), *Clinical Biochemistry of Domestic Animals,* 4th ed. (1989); G.R. CARTER and JOHN R. COLE, JR. (eds.), *Diagnostic Procedures in Veterinary Bacteriology and Mycology,* 5th ed. (1990); and CHARLES M. FRASER *et al.* (eds.), *The Merck Veterinary Manual: A Handbook of Diagnosis, Therapy, and Disease Prevention and Control for the Veterinarian,* 7th ed. (1991), are general references on physical and laboratory diagnostic techniques. (C.E.Co./Ed.)

Diseases of plants. General works include G.C. AINSWORTH, *Introduction to the History of Plant Pathology* (1981), a review of the developments in the field of plant pathology and the influence of plant diseases on history; GAIL L. SCHUMANN, *Plant Diseases: Their Biology and Social Impact* (1991), a discussion of the social and cultural influence of plant diseases; and E.C. LARGE, *The Advance of the Fungi* (1940, reissued 1962), a popular account of plant disease epidemics and how they have influenced economic and political history.

Compilations of practical information are A. JOHNSTON and C. BOOTH (eds.), *Plant Pathologist's Pocket Book,* 2nd ed. (1983), on the identification, isolation, and culture of plant pathogens; MICHAEL D. SMITH (ed.), *The Ortho Problem Solver,* 3rd ed. (1989), a handbook for indoor and outdoor plants; *Westcott's Plant Disease Handbook,* 5th ed. rev. by R. KENNETH HORST (1990), a comprehensive reference covering plants grown in the United States, for professional and amateur gardeners; LOUIS PYENSON, *Plant Health Handbook* (1981), a guide for the amateur gardener; G.R. DIXON, *Plant Pathogens and Their Control in Horticulture* (1984), with both host and microorganism/disease indexes; I.M. SMITH *et al.* (eds.), *European Handbook of Plant Diseases* (1988), a reference for professional plant pathologists and for advanced study in the field, covering economically important diseases of crops and forest trees in Europe; PASCAL P. PIRONE, *Diseases and Pests of Ornamental Plants,* 5th ed. (1978), an excellent reference for gardeners and landscape professionals; RUBERT BURLEY STREETS, *The Diagnosis of Plant Diseases: A Field and Laboratory Manual Emphasizing the Most Practical Methods for Rapid Identification* (1982); WILLIAM R. JARVIS, *Managing Diseases in Greenhouse Crops* (1992); and H. DAVID THURSTON, *Tropical Plant Diseases* (1984), a discussion of important diseases of major tropical crops. The *Compendium of Plant Diseases* is an outstanding series of well-illustrated books by experts in each field, designed to assist in the identification, prevention, and control of major plant diseases and disorders of specific crops.

College-level texts include GEORGE N. AGRIOS, *Plant Pathology,* 3rd ed. (1988), a comprehensive discussion of parasitism and pathogenicity and the biochemistry of host-pathogen relationships; J.G. MANNERS, *Principles of Plant Pathology,* 2nd ed. (1993), an investigation of the physiology and genetics of host-pathogen interactions, disease epidemiology, and control; DANIEL A. ROBERTS and CARL W. BOOTHROYD, *Fundamentals of Plant Pathology,* 2nd ed. (1984), an examination of causal agents, symptoms, and control of plant diseases; C.H. DICKINSON and J.A. LUCAS, *Plant Pathology and Plant Pathogens,* 2nd ed. (1982), an overview of plant disease with extensive coverage of host-pathogen interactions at both the cellular and subcellular levels; and GEORGE B. LUCAS, C. LEE CAMPBELL, and LEON T. LUCAS, *Introduction to Plant Diseases: Identification and Management,* 2nd ed. (1992), a survey of the causes, impact, and management of plant diseases. Specific aspects are treated in depth in the following references: KURT J. LEONARD and WILLIAM E. FRY (eds.), *Plant Disease Epidemiology,* vol. 1 (1986), covering population dynamics and management of disease-causing agents; JÜRGEN KRANZ (ed.), *Epidemics of Plant Diseases,* 2nd completely rev. ed. (1990), a presentation of the latest mathematical and statistical methods in use for analysis and modeling of plant disease epidemics; R.K.S. WOOD and G.J. JELLIS (eds.), *Plant Diseases: Infection, Damage, and Loss* (1984), a comprehensive assessment; WILLIAM F. BENNETT (ed.), *Nutrient Deficiencies & Toxicities in Crop Plants* (1993), an examination of the role of nutrients on the health of major crop plants; R.D. DURBIN (ed.), *Toxins in Plant Disease* (1981), on the role of microbial toxins in the plant disease cycle; P.G. AYRES (ed.), *Effects of Disease on the Physiology of the Growing Plant* (1981), a compilation of seminar papers; GEORGE W. BRUEHL, *Soilborne Plant Pathogens* (1987); DAVID F. FARR *et al., Fungi on Plants and Plant Products in the United States* (1989), a comprehensive discussion; MASAO GOTO, *Fundamentals of Bacterial Plant Pathology* (1992), a discussion of the morphology, taxonomy, and physiology of phytopathogenic bacteria; J.F. BRADBURY, *Guide to Plant Pathogenic Bacteria* (1986), identifying phytopathogenic bacteria and the diseases they cause; DAVID C. SIGEE, *Bacterial Plant Pathology: Cell and Molecular Aspects* (1993), including discussions of interactions with host cells, virulence factors, and genetics; R.E.F. MATTHEWS, *Plant Virology,* 3rd ed. (1991), a comprehensive text covering all aspects of plant-infecting viruses, and *Diagnosis of Plant Virus Diseases* (1993), a discussion of strategies; R.T. PLUMB and J.M. THRESH (eds.), *Plant Virus Epidemiology* (1983), a collection of works by international authorities in the field of plant virology, including several case histories of particularly important diseases; KARL MARAMOROSCH (ed.), *Plant Diseases of Viral, Viroid, Mycoplasma, and Uncertain Etiology* (1992); KARL MARAMOROSCH and S.P. RAYCHAUDHURI (eds.), *Mycoplasma Diseases of Crops* (1988), a collection of discussions regarding detection of mycoplasmas, their interactions with plants, insects, and viruses, and their control; VICTOR H. DROPKIN, *Introduction to Plant Nematology,* 2nd ed. (1989), on the classification and characterization of plant-parasitic nematodes; M. WAJID KHAN (ed.), *Nematode Interactions* (1993); KERRY F. HARRIS and KARL MARAMOROSCH (eds.), *Pathogens, Vectors, and Plant Diseases: Approaches to Control* (1982), on the identification and control of insect and nematode vectors of plant diseases; ANNE R. LESLIE and GERRIT W. CUPERUS (eds.), *Successful Implementation of Integrated Pest Management for Agricultural Crops* (1993); H. DAVID THURSTON, *Sustainable Practices for Plant Disease Management in Traditional Farming Systems* (1992), a discussion of integrated control of phytopathogenic microorganisms; RICHARD N. STRANGE, *Plant Disease Control: Towards Environmentally Acceptable Methods* (1993), an ecologically sensitive analysis of current methods of disease prevention and control; R. JAMES COOK and KENNETH F. BAKER, *The Nature and Practice of Biological Control of Plant Pathogens* (1983), a discussion of the influence of environment on the interactions among microorganisms and crop plants; ARTHUR W. ENGELHARD (ed.), *Soilborne Plant Pathogens: Management of Diseases with Macro- and Microelements* (1989), on the effects of fertilization, nutrition, and pH on diseases caused by soilborne plant pathogens; P.R. DAY and G.J. JELLIS (eds.), *Genetics and Plant Pathogenesis* (1987), covering the genetic aspects of disease and pest resistance; and M.S. WOLFE and C.E. CATEN (eds.), *Populations of Plant Pathogens: Their Dynamics and Genetics* (1987), a collection of essays with ideas and concepts relevant to the long-term development of disease-control methods based on population dynamics. (M.J.P./R.M.P.)

Religious Doctrines and Dogmas

The development of doctrines and dogmas—*i.e.*, the explications and officially acceptable versions of religious teachings—has significantly affected the traditions, institutions, and practices of the religions of the world. Doctrines and dogmas also have influenced and been influenced by the ongoing development of secular history, science, and philosophy.

This article is divided into the following sections:

GENERAL NATURE OF DOCTRINE AND DOGMA

DISTINCTIONS BETWEEN DOCTRINE AND DOGMA

Doctrine in theology (Latin *doctrina*; Greek *didaskalia, didachē*) is a generic term for the theoretical component of religious experience. It signifies the process of conceptualizing the primal—often experiential or intuitive—insights of the faith of a religious community in support of rationally understood belief. Doctrines seek to provide religion with intellectual systems for guidance in the processes of instruction, discipline, propaganda, and controversy. Dogma (Latin *decretum*, Greek *dogma*) has come to have a more specific reference to the distillate of doctrines: those first (basic or axiomatic) principles at the heart of doctrinal reflection, professed as essential by all the faithful.

This distinction appears in Christianity in the New Testament, in which *didaskalia* means "basic teachings" (as in I and II Tim.) whereas *dogma* is used only in the sense of an official judgment or decree (as in Acts 16:4). Later, however, many theologians of the early church (including, for example, Origen, St. Cyril of Jerusalem, and St. Jerome) use the term dogma in the sense of doctrine. In Eastern Christianity, the theologian St. John of Damascus popularized the term "orthodoxy" (literally "correct views") to connote the sum of Christian truth. In Western Christianity, the great medieval theologian St. Thomas Aquinas chose the phrase "articles of faith" to denote those doctrines that are solemnly defined by the church and are considered to be obligatory for faith. As late as the Roman Catholic reformatory Council of Trent (1545–63), "doctrine" and "dogma" were still roughly synonymous.

Most modern historians, however, have stressed their difference. According to J.K.L. Gieseler, a 19th-century German church historian, in *Dogmengeschichte,*

> Dogma is not doctrinal opinion, not the pronouncement of any given teacher, but doctrinal statute (*decretum*). The dogmas of a church are those doctrines which it declares to be the most essential contents of Christianity.

A modern church historian, Adolf von Harnack, sought to explain the rise of dogma in Christianity as the specific consequence of an alien blend of Greek metaphysics and Christian thought that had been rendered obsolete by Protestantism's appeal to Scripture and history. The German Roman Catholic dogmatician Karl Rahner's contrasting definition, in *Sacramentum Mundi,* points to a perennial process:

> Dogma is a *form* of the abiding vitality of the deposit of faith in the church which itself remains always the same.

FUNCTIONS OF DOCTRINES AND DOGMAS

The functions of doctrines and dogmas vary in the several religious traditions according to the stress each puts on the importance of the rational conceptualization of religious truth first glimpsed in images, symbols, and parables. In what are viewed by some scholars as the more mystical religions of the East, doctrines are usually designed to serve as catalytic clues to religious insight (*e.g.*, the notions of Nirvāṇa, or the goal of the religious life, in Hinduism, Jainism, and Buddhism). In what are regarded as the more

The rational conceptualization of religious truth

personalistic religions of the West, doctrines and dogmas tend to function as aids to theological reflection (*e.g.*, the concept of God's unity in Judaism, Christianity, and Islām). In all the higher religions, doctrines and dogmas emerge and develop in the service of instruction for the faithful: interpreting their sacred Scriptures, understanding their obligations and duties, and safeguarding the lines between allowable diversity and actual error—all of which help to chart the religious pathway to wisdom, rectitude, and fulfillment. Theology (which utilizes doctrines and dogmas) is, according to the medieval Christian theologian and churchman St. Anselm of Canterbury, "faith seeking rational self-understanding."

The normative function of doctrinal formulation is a typically vain effort to fix and conserve an interpretation of the original dogmas of a given tradition. The themes of *saṃsāra* (the process of reincarnation) and *karman* (the law of cause and effect) are shared by Hinduism, Jainism, and Buddhism, though with quite different doctrinal explicitations and consequences. Analogous developments are evident in other traditions.

A third function of doctrine is polemical: the defense of the faith against misinterpretation and error, within or without a religious tradition. Given the invariably pluralistic character of theological reflection, there is a constant tension between the concern for identity and continuity of the tradition, on the one hand, and for deeper and richer comprehension of truth itself, on the other. Over against this there is in most cultures a concurrent rivalry with other religions, with their contrary doctrinal claims, and beyond that, the challenges of secular wisdom and unbelief. This calls forth a special sort of doctrinal formulation: apologetics, the vindication of the true faith against its detractors or disbelievers.

The problem of primal authority

At the heart of all efforts to support religious faith lies the problem of primal authority. It is required of a doctrinal statement that it be clear and cogent, but doctrines always point past their logical surface to some primitive revelation or deposit of faith. The appeal may be to any one of a number of primary authoritative positions: to the memory of a founder (as in Zoroastrianism), or a prophet (Moses in Judaism), or to ancient Scriptures (*e.g.*, the Veda and *Upaniṣad*s in Hinduism), or an exemplary event (as in Gautama, the Buddha's "enlightenment"), or to God's self-disclosure (as in the Torah, or Law, for Judaism, or in Jesus Christ in Christianity, or Muḥammad's revelations to Islām). Here again, the diversity between doctrines ("allowable interpretations") and the stability of dogmas ("essential teaching") points to the vexed problem of doctrinal development in history that is apparent in all the traditions.

DEVELOPMENT

Every religion has a history of doctrine that is more than a replication of the deposit of faith. Doctrine, as a mode of pedagogy, is conservative of its tradition; as a mode of inquiry, it may be innovative, generating new insights that alter the rhetoric of conventional teaching and, sometimes, its substance as well. There are, of course, wide variations. The persistent continuities between ancient Zoroastrianism and its modern form, Parsiism, or in Jainism, are clearer than those between primitive Hinduism and modern Vedānta (a Hindu philosophical system). All forms and sects of Buddhism appeal jointly to the Three Jewels (the Buddha; the *dharma*, or law; and the *saṅgha*, or monastic order) but are irreconcilable in their differences of interpretation and practice. In each case, the question as to what constitutes legitimate development (*e.g.*, the rival claims of Theravāda, or "Way of the Elders," and Mahāyāna, or "Greater Vehicle," in Buddhism) is left undetermined.

All Jews profess devotion to Torah, even in their disagreements over its authentic observance. Christians profess a common loyalty to the Bible and a common acceptance of the twin dogmas of the Trinity (that the one God is three Persons—Father, Son, and Holy Spirit) and the God-Manhood of Jesus (that Christ is both divine and human) but then divide in their doctrinal systems as they have developed historically. Later dogmas (*e.g.*, transubstantiation, the teaching that the substance of the bread and wine in the Lord's Supper is changed into the substance of the body and blood of Christ, with the properties of the bread and wine remaining unchanged) were defined by the Latin Church without concurrence from Eastern Orthodoxy; the modern dogmas of the Roman Catholic Church (*i.e.*, the immaculate conception of the Virgin Mary, the bodily assumption into heaven of the Virgin Mary, and papal infallibility) were defined in separation from both the Eastern and Protestant consensus. Protestantism has continued an emphasis on its distinctive dogmas of "grace alone" (*sola gratia*), "faith alone" (*sola fide*), and "Scripture alone" (*sola Scriptura*) but has nevertheless undergone immense change and proliferation.

Islām lays great stress on doctrinal stability that is focussed in the Qur'ān, the *sunnah* (custom or tradition), and the consensus (*ijmā'*) of its jurists (*'ulamā'*). Even so, it has produced doctrinal variants—especially in the medieval period—that are as disparate as the mysticism of the Iranian-born philosopher al-Ghazālī and the rationalism of the Spanish philosopher Averroës and the Persian philosopher Avicenna.

Views of doctrinal development

The process of doctrinal development has been explained variously as a process of logical unfolding or of organic growth, or else as a process of purgations of error and restorations of the original deposit. The notion of a logical unfolding assumes that all that has developed in a religious tradition over the course of its history was already implicit in its original foundation and subsequently had only to become more fully understood. In the case of the doctrine of the Trinity in Christianity, for example, it is argued that the abundant references in the New Testament and the earliest liturgies to God as Father, Son, and Holy Spirit required the development of a dogma that would make explicit the essential Christian trinitarian conviction. Similarly, the dogma on the nature of Christ is understood as the logical outcome of sustained reflection on the testimony about Jesus as the Christ in the Bible and in the apostolic tradition. In the notion of logical unfolding, even in its continual development, truth remains forever unchanged.

Theories of organic development stress the fact that the history of doctrine includes more than explicit formulation of implicit revelation. Such theories take into account the ways in which religious thought is affected by "contemporary" science, philosophy, and historical crises (*e.g.*, the "Copernican revolution" in astronomy, the Renaissance, and other such events). The holders of this view are convinced, however, that all such historical supplementations have been integrated into the original deposit and thus exhibit the power of the religious organization (*e.g.*, the church) to grow and change without substantial alteration of its identity. Thus the 19th-century Roman Catholic cardinal J.H. Newman, in his *Essay on the Development of Christian Doctrine* (1845), argued that

> ... the highest and most wonderful truths, though communicated to the world once for all by inspired teachers could not be comprehended all at once by the recipients, but, ... have required only the longer time and deeper thought for their full elucidation (*Introduction*, pp. 29–30).

Newman also believed that this process was safeguarded by the authority of the teaching that would even allow for revisions and occasional corrections of antecedent.

Protestants, by and large, have been more impressed by the lapses and deviations they see in church history and doctrine and thus have tended to construe authentic "development" in terms of a perennial recourse to Scripture and apostolic tradition. Such a view takes historical flux for granted and is less sensitive to the problem of historical continuity.

In all traditions, the course of doctrinal development is crucially affected by the occasional emergence of profound and powerful thinkers who have gathered up scattered elements in their various traditions in freshly relevant syntheses, altering thereby the subsequent history of that tradition. This can be seen, for example, in the North African theologian Augustine's contributions to the making of Latin Christianity and in the matching services of St. John of Damascus in Eastern Orthodoxy. Such also was

the role and contribution of Moses Maimonides in medieval Judaism (*e.g.*, the Thirteen Articles of Faith in his commentary on the Mishna) and of St. Thomas Aquinas in medieval Christianity (*e.g.*, *Summa theologiae*). The 16th-century Reformers Martin Luther and John Calvin gave Protestantism its classical form, to be followed by yet other and different system builders (*e.g.*, Friedrich Schleiermacher in the 19th century and Karl Barth in the 20th century).

Each theory of development has had its own distinctive prescription for doctrinal stability and doctrinal change. In Christianity, Eastern Orthodoxy locates its authority in "Holy Tradition," which is fixed and guided by the dogmas proclaimed by the ecumenical councils. Roman Catholicism relies on the magisterium (teaching authority) of the church, which is directed by the bishops as a "college" (*collegium episcoporum*) and supremely by the bishop of Rome as their collegial head. Protestantism has sought to bind both tradition and the church to the authority of Holy Scripture, with the resulting problem of specifying what is to be regarded as truly authoritative interpretations of Scripture.

THE RELATION OF FAITH, REASON, AND RELIGIOUS INSIGHT TO DOCTRINE AND DOGMA

The interplay of faith and reason in religious experience

Insofar as doctrines and dogmas represent conceptualizations of the human encounter with the divine mystery, they are bound to reflect the interplay of faith and reason in religious experience and to imply some notion of levels and stages in the progress of believers as they move from the threshold of faith toward its fulfillment. Doctrine is concerned with communication and consensus, with the exposure of the religious vision to rational probes and queries. There is, therefore, a tension in all religions between mystical intuition and logical articulation, between insight and dialogue. Most traditions agree that perfect understanding is a goal that lies beyond a "simple faith" and the routine observance of rites and duties. Most of them also agree that the utmost pinnacle of religious insight is ineffable. One mode of differentiation between doctrinal traditions, therefore, is their relative openness or resistance to the auxiliary services of philosophy and science of faith's fulfillment.

In the majority of the religions of the East, very broadly, reason's chief role is the purgation of illusion and self-deception so that souls may follow the ways of wisdom and right conduct to their true fulfillment in Nirvāṇa. The Hindu passes from the initiatory level of "the student" (who is dependent on a teacher, guru) to the ambivalent freedom of "the householder," to the great freedom of "the forest dweller," to the fullest freedom of the *sannyāsin* (an enlightened ascetic). Reason, which is chiefly reflective, assists at every stage in perfecting faith's self-understanding. In Buddhism, one follows the *dharma* from *saddha* (which is practical knowledge of one's religious obligations), to *jñāna* (rational insight), to *vijñāna* (mystical illumination).

In most of the religions of the West, again very broadly, the primary function of reason is seen to be that of rendering the mysteries of faith as intelligible as possible, in support of the intellectual love of God. In Judaism, progress in the knowledge of Torah is focussed in the Bible and the Talmud (commentaries on the Law), guided by the twin hermeneutical (critical interpretive) principles of Halakha (the oral precepts and decisions of the rabbis) and of Haggada (instructive stories, parables, and other similar devices).

Variations in Islām range from the rigid orthodoxy of the Ḥanbalites (a conservative school of law following the teachings of Ibn Ḥanbal), to the rational liberalism of the Muʿtazilites (a school of law utilizing Greek philosophical methods), to the dialectical doctrines (*kalām*) of the Arabian theologian al-Ashʿarī and the Turkish philosopher al-Fārābī. All of these, however, are anchored in the twin dogmas of the unity of God and the prophetic office of Muhammad. Spiritual progress is measured by the believer's faithfulness in obedience to the "Five Pillars," or religious duties, including prayer, fasting, and the pilgrimage to Mecca.

In Christianity, the dialectic between faith and reason has ranged from the fideism (emphasis on faith) of the 2nd-century North African theologian Tertullian to the intellectualism of Thomas Aquinas. An ancient distinction between faith as bare assent to orthodox doctrine (*fides informis*) and faith as existential trust in God's grace (*fides formata*) gave rise to the further distinction between faith as a set of doctrines to be believed (*fides quae creditur*) and faith as personal involvement (*fides qua creditur*). Philipp Melanchthon, a 16th-century Lutheran Reformer, stressed the point that even the devils are "orthodox" (having "dead faith") but to no avail, since only those who have embraced God's reconciling love (*fiducia*) receive the benefits of salvation ("living faith"). In general, this distinction has become standard in Protestantism.

Faith as assent and as trust

CHANGING CONCEPTIONS

In all the great religious traditions, and between them, the clash of doctrines and dogmas has, more often than not, been polemical. The *odium theologorum* ("bitterness of the theologians") of which Melanchthon once complained so plaintively has been notorious. Within the several traditions, doctrinal disputes have sometimes led to division or else have accompanied divisions caused otherwise. In relationships between the great world religions, dogmas and doctrines have usually been regarded as mutually exclusive. There are, however, significant signs of change in this attitude. The rise and spread of the ecumenical movement in the 20th century and notable advances in the comparative study of world religions reflect an enlarged commitment to the widest possible community of mutual religious interests. The "Decree on Ecumenism" and its "Declaration on the Relationship of the Church to Non-Christian Religions" of the Roman Catholic second Vatican Council (1962–65) are signal instances of this new disposition.

(A.C.O.)

MAJOR THEMES AND MOTIFS

Creation

Doctrines of creation are philosophical and theological elaborations of the primal myth of creation within a religious community. The term myth here refers to the imaginative expression in narrative form of what is experienced or apprehended as basic reality (see also MYTH AND MYTHOLOGY). The term creation refers to the beginning of things, whether by the will and act of a transcendent being, by emanation from some ultimate source, or in any other way.

NATURE AND SIGNIFICANCE

The myth of creation is the symbolic narrative of the beginning of the world as understood by a particular community. The later doctrines of creation are interpretations of this myth in light of the subsequent history and needs of the community. Thus, for example, all theology and speculation concerning creation in the Christian community are based on the myth of creation in the biblical book of Genesis and of the new creation in Jesus Christ. Doctrines of creation are based on the myth of creation, which expresses and embodies all of the fertile possibilities for thinking about this subject within a particular religious community.

The basis for man's placement and orientation in the world

Myths are narratives that express the basic valuations of a religious community. Myths of creation refer to the process through which the world is centred and given a definite form within the whole of reality. They also serve as a basis for the orientation of man in the world. This centring and orientation specify man's place in the universe and the regard he must have for other humans, nature, and the entire nonhuman world; they set the stylistic tone that tends to determine all other gestures, actions,

and structures in the culture. The cosmogonic (origin of the world) myth is the myth par excellence. In this sense, the myth is akin to philosophy, but, unlike philosophy, it is constituted by a system of symbols; and because it is the basis for any subsequent cultural thought, it contains rational and nonrational forms. There is an order and structure to the myth, but this order and structure is not to be confused with rational, philosophical order and structure. The myth possesses its own distinctive kind of order.

Myths of creation have another distinctive character in that they provide both the model for nonmythic expression in the culture and the model for other cultural myths. In this sense, one must distinguish between cosmogonic myths and myths of the origin of cultural techniques and artifacts. Insofar as the cosmogonic myth tells the story of the creation of the world, other myths that narrate the story of a specific technique or the discovery of a particular area of cultural life take their models from the stylistic structure of the cosmogonic myth. These latter myths may be etiological (*i.e.*, explaining origins); but the cosmogonic myth is never simply etiological, for it deals with the ultimate origin of all things.

The cosmogonic myth thus has a pervasive structure; its expression in the form of philosophical and theological thought is only one dimension of its function as a model for cultural life. Though the cosmogonic myth does not necessarily lead to ritual expression, ritual is often the dramatic presentation of the myth. Such dramatization is performed to emphasize the permanence and efficacy of the central themes of the myth, which integrates and undergirds the structure of meaning and value in the culture. The ritual dramatization of the myth is the beginning of liturgy, for the religious community in its central liturgy attempts to re-create the time of the beginning.

The ritual expression of creation: sacred time

From this ritual dramatization the notion of time is established within the religious community. To be sure, in most communities there is the notion of a sacred and a profane time. The prestige of the cosmogonic myth establishes sacred or real time. It is this time that is most efficacious for the life of the community. Dramatization of sacred time enables the community to participate in a time that has a different quality than ordinary time, which tends to be neutral. All significant temporal events are spoken of in the language of the cosmogonic myth, for only by referring them to this primordial model will they have significance.

In like manner, artistic expression in archaic or "primitive" societies, often related to ritual presentation, is modelled on the structure of the cosmogonic myth. The masks, dances, and gestures are, in one way or another, aspects of the structure of the cosmogonic myth. This meaning may also extend to the tools man uses in the making of artistic designs and to the precise technique he employs in his craft.

Mention has been made above of the fact that the cosmogonic myth situates mankind in a place, in space. This centring is at once symbolic and empirical: symbolic because through symbols it defines the spatiality of human beings in ontological terms (of being) and empirical because it orients them in a definite landscape. Indeed, the names given to the flora and fauna and to the topography are a part of the orientation of humans in a space. The subsequent development of language within a human community is an extension of the language of the cosmogonic myth.

The primordial structure of culture

The initial ordering of the world through the cosmogonic myth serves as the primordial structure of culture and the articulation of the embryonic forms and styles of cultural life out of which various and differing forms of culture emerge. The recollection and celebration of the myth enable the religious community to think of and participate in the fundamentally real time, space, and mode of orientation that enables them to define their cultural life in a specific manner.

TYPES OF COSMOGONIC MYTHS

The world as a structure of meaning and value has not appeared in the same manner to all human civilizations. There are, therefore, almost as many cosmogonic myths as there are human cultures. Until quite recently, the classification of these myths on an evolutionary scale, from the most archaic cultures to contemporary Western cultures (*i.e.*, from the assumedly simplest to the most complex) was the most dominant mode of ordering these myths. Recent 20th-century scholars, however, have begun to look at the various types of myths in terms of the structures that they reveal rather than considering them on an evolutionary scale that extends from the so-called simple to the complex, for, in a sense, there are no simple myths regarding the beginning of the world. The beginning of the world is simultaneously the beginning of the human condition, and it is impossible to speak of this beginning as if it were simple.

Creation by a supreme being. The 19th-century scholars who took an evolutionary survey of human culture and religion (*e.g.*, Sir James George Frazer and Edward Burnett Tylor) held that the notion of the creation of the world by a supreme being occurred only in the highest stage of cultural development.

Andrew Lang, a Scottish folklorist, challenged this conception of the development of religious ideas, for he found in the writings of anthropologists, ethnologists, and travellers evidence of a belief in a supreme being or high god among cultures that had been classified as the most primitive. This position was taken up and elaborated by an Austrian priest-anthropologist, Wilhelm Matthäus Schmidt, who reversed the evolutionary theory, holding that there was a primordial notion of a supreme being, a kind of original intellectual and religious conception of a single creator god, that degenerated in subsequent cultural stages. Though Schmidt's theories of cultural historical stages and diffusion and an original primordial revelation have for the most part been discredited and abandoned, the existence of a belief in a supreme being among primitive peoples (a notion discovered by Andrew Lang) has been proven and attested to over and over again by investigators of numerous cultures. This belief has been found among the cultures of Africa, the Ainu of the northern Japanese islands, Amerindians, south central Australians, the Fuegians of South America, and in almost all parts of the globe.

Primordial supreme beings or creator gods

Though the precise nature and characteristics of the supreme creator deity may differ from culture to culture, a specific and pervasive structure of this type of deity can be discerned. The following characteristics tend to be common: (1) he is all wise and all powerful. The world comes into being because of his wisdom, and he is able to actualize the world because of his power. (2) The deity exists alone prior to the creation of the world. There is no being or thing prior to his existence. No explanation can therefore be given of his existence, before which one confronts the ultimate mystery. (3) The mode of creation is conscious, deliberate, and orderly. This again is an aspect of the creator's wisdom and power. The creation comes about because the deity seems to have a definite plan in mind and does not create on a trial-and-error basis. In Genesis, for example, particular parts of the world are created seriatim; in an Egyptian myth, Kheper, the creator deity, says, "I planned in my heart," and in a Maori myth the creator deity proceeds from inactivity to increasing stages of activity. (4) The creation of the world is simultaneously an expression of the freedom and purpose of the deity. His mode of creation defines the pattern and purpose of all aspects of the creation, though the deity is not bound by his creation. His relationship to the created order after the creation is again an aspect of his freedom. (5) In several creation myths of this type, the creator deity removes himself from the world after it has been created. After the creation the deity goes away and only appears again when a catastrophe threatens the created order. (6) The supreme creator deity is often a sky god, and the deity in this form is an instance of the religious valuation of the symbolism of the sky.

In creation myths of the above type, the creation itself or the intent of the creator deity is to create a perfect world, paradise. Before the end of the creative act or sometime soon after the end of creation, the created order or the intent of the creator deity is thwarted by some fault of one

Rupture of primordial harmony and perfection

of the creatures. There is thus a rupture in the creation myth. In some myths this rupture is the cause of the departure of the deity from creation.

An African myth from the Dogon peoples of West Africa illustrates this point. In this myth the creator deity first creates an egg. Within the egg are two pairs of twins, each pair consisting of one male and one female. These twins are supposed to mature within the egg, becoming at maturation androgynous (both male and female) beings, the perfect creatures to inhabit the earth. One of the twins breaks from the egg before maturation because he wishes to dominate the creation. In so doing he carries a part of the egg with him, and from this he creates an imperfect world. The creator deity, seeing what he has done, sacrifices the other twin to establish a balance in the world. The creation is sustained by this sacrifice, and it is now ambiguous, instead of the perfect world intended by the god.

This myth not only shows how a rupture takes place within the myth itself but also points out the fact that the characteristics of the supreme creator deity noted above seldom exist apart from other mythological contexts. The widespread symbols of dualism (the divine twins), the cosmic egg, and sacrifice are basic themes in the structure of this African creation myth. In myths of this kind, however, prominence must always be given to the might of a powerful creator sky deity under whose aegis the created order comes into being.

Creation through emergence. In contrast to the creation by a supreme sky deity, there is another type of creation myth in which the creation seems to emerge through its own inner power from under the earth. In this genre of myth, the created order emerges gradually in continuous stages. It is similar to a birth or metamorphosis of the world from its embryonic state to maturity. The symbolism of the earth or a part of the earth as a repository of all potential form is prominent in this type of myth. In some myths of this type (*e.g.*, the Navajo myth of emergence), the movement from a lower stage to a higher one is initiated by some fault of the people who live under the earth, but these faults are only the parallels of an automatic upper movement in the earth itself.

From the embryonic or inchoate to the mature and definite

Just as the supreme-creator-deity myth forms a homology to the sky, the emergence myth forms a homology to the earth and to the childbearing woman. In many cases the emergence of the created order is analogous to the growth of a child in the womb and its emission at birth. This symbolism is made clear in a Zuni myth that states,

> Anon is the nethermost world, the seed of men and creatures took form and increased; even as in eggs in warm places speedily appear . . . Everywhere were unfinished creatures, crawling like reptiles one over another, one spitting on another or doing other indecencies . . . until many among them escaped, growing wiser and more manlike.

The underworlds prior to the created order appear chaotic; the beings inhabiting these places seem without form or stability, or they commit immoral acts. The seeming chaos is moving toward a definite form of order, however, an order latent in the very forms themselves rather than from an imposition of order from the outside.

From another perspective the emergence myth is homologous to the seed. When the homologue of the seed is referred to, the meaning of fertility and death are at once introduced. The seed must die before it can be reborn and actualize its potentiality. This symbolism is dramatically presented in a wide range of funerary rites: one is buried in the earth in hope of a renewal from the earth, or the earth is the repository of the ancestors from whom the new generation emerges. In every case, emergence myths demonstrate the latent potency immanent in the earth as a repository of all life forms.

Creation by world parents. Closely related to the above type of myth is the myth that states that the world is created as the progeny of a primordial mother and father. The mother and father are symbols of earth and sky, respectively. In myths of this kind, the world parents generally appear at a late stage of the creation process; chaos in some way exists before the coming into being of the world parents. In the Babylonian myth *Enuma elish*, it is stated,

> When on high the heaven had not been named
> Firm ground below had not been called by name,
> Naught but primordial Apsu, their begetter,
> (And) Mummu-Tiamat, she who bore them all,
> Their waters comingling as a single body;

The Maori make the same point when they state that the world parents emerge out of *po*. *Po* for the Maori means the basic matter and the method by which creation comes about. There is thus some form of reality before the appearance of the world parents.

From inertness to activity

Even though the world parents are depicted and described as in sexual embrace, no activity is taking place. They appear as quiescent and inert. The chthonic (underworld) structure of the earth as latent potentiality tends to dominate the union. The parents are often unaware that they have offspring, and thus a kind of indifference regarding the union is expressed. The union of male and female in sexual embrace is another symbol of completeness and totality. As in the African myth from the Dogon referred to above, sexual union is a sign of androgyny (being both male and female) and androgyny, in turn, a sign of perfection. The indifference of the world parents is thus not simply a sign of ignorance but equally of the silence of perfection. The world parents in the Babylonian and Maori myths do not wish to be disturbed by their offspring. As over against the parents, the offspring are signs of actuality, fragmentation, specificity; they define concrete realities.

The separation of the world parents is again a rupture within the myth. This separation is caused by offspring who wish either to have more space or to have light, for they are situated between the bodies of the parents. In some myths the separation is caused by a woman who lifts her pestle so high in grinding grain that it strikes the sky, causing the sky to recede into the background, thus providing room for the activities of mankind. In both cases an antagonistic motive must be attributed to the agents of separation. In the Babylonian and Maori versions of this myth, actual warfare takes place as a result of the separation.

Over against the primordial union of the world parents, there is the desire for knowledge and a different orientation in space. After the separation, lesser deities related to solar symbolism take precedence in the creation. The sun and light must be seen in these myths as representing the desire for a humanizing and cultural knowledge as over against the passive and inert forms of the union of the parent deities. From the point of separation, the mythic narrative of the world-parent myths states how different forms of cultural knowledge are brought to man by the offspring, the agents of separation. The separation of the world parents is the sign of a new cosmic order, an order dedicated to the techniques, crafts, and knowledge of culture.

Creation from the cosmic egg. In the Dogon myth referred to above, the creation deity begins the act of creation by placing two embryonic sets of twins in an egg. In each set of twins is a male and female; during the maturation process they are together thus forming androgynous beings. In a Tahitian myth, the creator deity himself lives alone in a shell. After breaking out of the shell, he creates his counterpart, and together they undertake the work of creation.

A Japanese creation narrative likens the primordial chaos to an egg containing the germs of creation. In the Hindu tradition the creation of the world is symbolized in the Chandōgya *Upaniṣad* by the breaking of an egg, and the universe is referred to as an egg in other sources. The Buddhists speak of the transcending of ordinary existence, the realization of a new mode of being, as breaking the shell of the egg. Similar references to creation through the symbol of the egg are found in the Orphic texts of the Greeks and in Chinese myths.

The egg is a symbol of the totality from which all creation comes. It is like a womb containing the seeds of creation. Within the egg are the possibilities of a perfect creation (*i.e.*, the creation of androgynous beings). The egg, in addition to being the beginning of life, is equally a symbol of procreation, rebirth, and new life. In a version

of the Dogon, one of the twins returns to the egg in order to resuscitate the other.

The cosmogonic water and the diver animal or diver devil

Creation by earth divers. Two elements are important in myths of this type. There is, first, the theme of the cosmogonic water representing the undifferentiated waters that are present before the earth has been created. Secondly, there is an animal who plunges into the water to secure a portion of earth. The importance of the animal is that the creature agent is a prehuman species. This version of the myth is probably the oldest version of this genre. This basic structure of the earth-diver myth has been modified in central Europe in myths that relate the story of the primordial waters, God, and the devil. In these versions of the earth-diver myth, the devil appears as God's companion in the creation of the world. The devil becomes the diver sent by God to bring earth from the bottom of the waters. In most versions of this myth, God does not appear to be omniscient or omnipotent, often depending on the knowledge of the devil for certain details regarding the creative act—details that he learns through tricks he plays upon the devil.

In still different versions of this myth, the relationship between God and the devil moves from companionship to antagonism; they become adversaries, though they remain as co-creators of the world. The fact that the devil has had a part in the creation of the world is one way of explaining the origin and persistence of evil in the world.

Mircea Eliade, a noted 20th-century historian of religions, has pointed to another theme in certain Romanian versions of this myth. After God has instructed the devil to dive to the bottom of the waters and bring up the earth, the devil obeys, diving several times before he is able to bring up and hold on to a small portion of earth. After the creation of the world from this small portion of earth,

God's post-creation sleep

God sinks into a profound sleep. This sleep is a sign of mental exhaustion, for only the devil and a bee know the solution to certain details of the creation, and God must, with the help of the bee, trick the devil into giving him this vital information. God's sleep, according to Eliade, is a sign of his passivity and disinterest in the world after it has been created, and it harks back to certain archaic myths in which the supreme deity retires from the world after its creation, becoming disinterested and passive in the relationship to his work.

DOCTRINES OF CREATION

Some of the major types of creation myths have been presented above. It is from myths of this sort and their dominant themes that theological and philosophical speculation have been developed in the various religious communities throughout the world.

Basic mythical themes. *Primordiality.* In several myths it is stated that the primordial stuff of creation was some form of undifferentiated matter (*e.g.,* water, chaos, a monster, or an egg). It is from this undifferentiated matter that the world evolves or is made. In the case of the egg and monster symbols, there seems to be a notion of a definite original form, but the egg is undifferentiated; for its form is vague and embryonic, and the monster figure—containing all of the forms of chaos in a terrible way—expresses the theme that chaos is not only passive (as is water) but resists creation. Although creation results as a modification of the primordial matter, however, it is this matter that determines and sets the limits to the extension of the world in space and time. Thus, in communities in which myths of this type find their expression, there are periods of mythical-ritual renewal at certain cyclical periods in which the world returns to its original chaos to rise again out of this initial state.

The creator deity as sole determiner of creation's nature and destiny

When it is stated that the supreme being created the world and that there was no primordial matter prior to his being, then the determination of the world is in the mind and will of the deity. This leads to distinctive conclusions regarding the destiny of the world and man. The end (and meaning) of the world is thus not determined by the primordial matter but by the deity who created the world. It is he alone who determines the preservation, maintenance, and end of the world.

Dualisms and antagonisms. In emergence myths there seems to be an easy movement from one stage of creation to the next, but, as has been shown in the Navajo myth, at each subterranean level there is some type of antagonism among the developing embryonic creatures. This is one of the reasons for the separation of the creatures and the movement to another level. Though the emergence myths portray the mildest form of this antagonism, it is still present in myths of this sort.

In the world-parent myths there is antagonism between the offspring and the parents. This is a conflict between generations, expressing the desire of the children to determine their own place and orientation in existence against the passivity of the parents.

A dualism and antagonism is found again in the cosmic-egg myths, especially in the myths in which the egg contains twins. One twin wishes to take credit for the creation of the world alone, interrupting the harmonious growth within the egg before maturation. The faulty creation by this evil twin accounts for the ambiguous nature of the world and the origin of evil.

This observation applies equally to the dualistic structure in some versions of the earth-diver myths. The devil moves in the various versions of this myth from the companion to the antagonist of God, possessing the power to challenge the deity.

Sacrifice of primordial beings

Creation and sacrifice. In many cosmogonic myths, the narrative relates the story of the sacrifice and dismemberment of a primordial being. The world is then established from the body of this being. In the myth *Enuma elish,* the god Marduk, after defeating Tiamat, the primeval mother, divides the body into two parts, one part forming the heavens, the other, the earth. In a West African myth, one of the twins from the cosmic egg must be sacrificed to bring about a habitable world. In the Norse *Prose Edda,* the cosmos is formed from the body of the dismembered great Ymir, and, in the Indian Ṛgveda, the cosmos is a result of the sacrifice of man.

In these motifs of sacrifice, something similar to the qualification of the undifferentiated matter of creation is suggested, for, just as the primal stuff of creation must be differentiated before the world appears, the sacrifice of primordial beings is a destruction of the primal totality for the sake of a specific creation.

When the victim of the sacrifice is a primal monster, the emphasis is on the stabilization of the creation through the death of the monster. The monster symbolizes the strangeness and awesomeness occurring when a new land or space is occupied. The "monster" of the place is the undifferentiated character of the space and must be immobilized before the new space can be established.

In a myth from Ceram (Molucca Islands), a beautiful girl, Hainuwele, has grown up out of a coconut plant. After providing the community with their necessities and luxuries, she is killed and her body cut into several pieces, which are then thrown over the island. From each part of her body a coconut tree grows. It is only after the death of Hainuwele that mankind becomes sexual; that is, the murder of Hainuwele enables mankind to have some determination in the process of bringing new life into the world.

Theological and philosophical doctrines. Myths and poetic renderings in legends, sagas, and poetry express the basic cultural insights into some of the elements involved in the human consciousness about creation. Theological, philosophical, and scientific theory are types of rationalizations of these basic insights in terms of the particular culture and historical periods of the cultures in question.

The attempt to integrate the meanings of primordiality, dualisms and antagonisms, sacrifices, and ruptures and to meet demands of some kind of logical order and, at the same time, keep alive the meaning of these structures as religious realities, objects of worship, and a charter for the moral life, has led to the development of doctrines.

In "primitive" and archaic societies, the correct ritual enactment of mythical symbols ensures the order of the world. These rituals usually take place at propitious moments (*e.g.,* at the birth of a child, marriage, the founding of a new habitation, the erection of a house or temple, the beginning of a new year). In each case, the seemingly

practical activities imitate the mythic structure of the first beginning.

Theological and philosophical speculations and controversies centre within and between religious communities over the issues of the primordial nature of reality, dualisms, the process of creation, and the nature of time and space. A doctrine of creation must contain or suggest the manner in which all cultural meanings, both empirical and abstract, constitute an integral totality. Speculations that are based on the initial insights of a mythical theme explicate some principle in the myth as a basis for generalization and logical form on which all elements and themes may be ordered.

Transcendence and otherness. Doctrinal positions may be modelled around any or all of the themes of the cosmogonic myth. If the emphasis falls upon creation by a high god through his thought, word, or other mode, the problem of the otherness and difference between creator and creature becomes a source of theological discussion and philosophical speculations. In Judaism, Christianity, and Islām, the classical locus of this issue is found. All of these religions have theological traditions that raise this problem. Related to this issue is the transcendence and arbitrary action of the creator deity. Because he is prior to the world and its creatures, the question arises whether there are modes of creaturely knowledge or apprehension that are capable of knowing him; of whether he is subjected to the same categories of being as his creatures; of whether his time and space are the same time and space of his creation.

The problem of difference between creator and creature

To some extent, the a priori nature of this type of deity creates an apparent dualism between the creator and the world and creatures. This dualism is mediated in various forms in the traditions. In Judaism it is mediated through nature and the covenant Yahweh has with his people; in Christianity through the mediatorship of his son, Jesus Christ; and in Islām through the sacred word of the Qur'ān by the prophet Muḥammad. Even within these traditions, however, the transcendent nature of the deity and his mediatorship through some other being or principle does not settle the doctrinal issue, for different cultural-historical periods of these traditions offer a variety of theological speculation concerning the nature and meaning of the deity, the world, and the mediator. The traditions offer a structure through which such speculation is ordered and clarified.

Creation through emanations. The theme of emergence is related to theological and philosophical notions of emanations from a single principle and the idea of the transmutation of being. Ideas of this kind are found in "primitive" religion (Dogon, Polynesian), in Taoism, and in the Pre-Socratic philosophers Thales and Anaximander.

In one version of the Dogon myth, creation proceeds from a small seed. Within the seed spontaneous movements begin. These movements, which burst from the shell of the seed and make contributions in space, create all forms of beings and the universe. Similarly, in the Polynesian myth Ta-aroa develops the world out of himself and the shell in which he lived.

The notion of the universe in a perpetual flux

A pervasive theme in Chinese thought is that of a universe in a perpetual flux. This flux follows a fixed and predictable pattern either of eternal oscillation between two apparently opposed poles or of a cyclical movement in a close orbit. The oscillation pattern is expressed by the Yin-Yang doctrine of Taoism. In the five element doctrine, a cyclical movement is correlated with the five elements, earth, wood, metal, fire, and water; these in turn form an equivalence with the third month of summer and with spring, autumn, summer, and winter, respectively. These parallelisms then form equivalences with the five directions, and they in turn with the five primary colors. Ancient Chinese thinkers never discuss an initial conscious act of creation. The cyclical movement itself produced the empirical and abstract form of the cosmos. The oscillation between the Yin and the Yang forms a correlation in all phenomena extending to the realms of time, space, number, and ethics.

Thales thought that the fundamental principle of cosmos was water. The earth floated on water; water was the natural cause of all things. Anaximander taught that there was an eternal undestructible something out of which everything arises and everything returns. In other words, the fundamental substratum of the world could not be an element of the world. The importance of Anaximander was in his use of the term *archē* ("beginning" or "rule") to refer to a principle unlike any other principle or element in the world to explain the cause of all other things in the universe.

Dualisms. Dualistic conceptions of creation come to the fore in the theme of earth-diver myths, in which there is an antagonism between the co-creators of the universe. This conception is present again in myths of divine twins and in Zoroastrianism where the Ormazd and Ahriman represent the creative and destructive principles in creation. In some sense this is not an ontological dualism for the first creative act of Ormazd was the limitation of time and thus the limitation of the power of Ahriman to carry out his destruction. Doctrines of this kind are related to the origin of evil in the world.

SKEPTICISM REGARDING CREATION

Alongside the various myths and doctrines regarding creation, there are equally skeptic positions concerning the unknowability of creation. This critique is present in several religious and philosophical traditions. It may be correlated with the mythical meaning of *deus otiosus,* the deity who retires from the world after his creation, or with the mythic theme from some earth-diver myths that emphasize the physical and intellectual fatigue of the deity after creation. In the first case, the removal of the deity from creation leaves no access to his plan or will; in the other case, because of the fatigue of the deity who has exhausted all of his knowledge in creation, there is thus nothing for man to learn from him.

In the Indian tradition the Rigveda, an ancient sacred text, expresses skepticism in this manner:

> He, the first origin of this creation, whether he formed it all or did not form it,
> Whose eye controls this world in highest heaven, he verily knows it, or perhaps he knows not.

The Buddha declared certain cosmological and metaphysical questions unanswerable. His refusal to answer questions of this kind gave rise to the "silence of the Buddha" as a philosophical style in Buddhism. They included such questions as: whether the world is eternal or not or both; whether the world is finite (in space) or infinite or both or neither.

In the Chinese tradition Kuo Hsiang (died AD 312) questioned the origin of the basic oscillation of the Taoist movement. For Hsiang there is no such thing as Non-Being for Being is the only reality. Being could not have evolved from Non-Being nor can it revert to Non-Being. As Kuo Hsiang put it,

> I venture to ask whether the Creator is or is not? If He is not, how can He create things? If He is, then (being one of these things), He is incapable of creating the mass of bodily forms. . . . The creating of things has no Lord; everything creates itself. Everything produces itself and does not depend on anything else. This is the normal way of the universe.

Skepticism of this same kind is expressed by Parmenides, a Pre-Socratic, and in the modern tradition of Western philosophy from Immanuel Kant's *Kritik der reinen Vernunft* (1st ed. 1781; Eng. trans., *Critique of Pure Reason,* 1929) to Ludwig Wittgenstein's *Tractatus Logico-Philosophicus* (1922). Skepticism of this kind about the nature of the cosmic order and especially about the ultimate origin of the universe places limitations on the possibility of the rational consciousness to authentically ask these questions. In some instances theologians have agreed and held to a notion of revelation as a response to these unanswerable questions. In other cases, the questions themselves have been labelled nonsensical.

The work of Hartshorne and Reese

Charles Hartshorne and William Reese, 20th-century U.S. philosophers, have attempted to clarify and criticize all possible rational reflections concerning the relationship of deity to the universe. They state two opposed positions. The first is that of classical theism in which there is the admission of plurality, potentiality, becoming, as a

secondary form of existence outside of God. The other position, that of classical pantheism, says that though God includes all within himself, he cannot be complex or mutable, for such categories only express human ignorance and illusion. They attempt to overcome this dilemma by combining these contrary poles into a dipolar conception of the meaning of deity. Because classical theism is primarily a Western approach to the problem and classical pantheism an Eastern approach, the dipolar conception is at the same time a synthesis of Western and Eastern thought. In addition to this, these philosophers set forth a method of analyzing all conceptions of deity and world according to basic religious and rational categories. As metaphysicians they go far in refuting the skepticism regarding rational knowledge of the relationship between the deity and the universe. (C.H.Lo.)

Eschatology

Eschatology (the doctrine of last things) is originally a Western term, referring to Jewish and Christian beliefs about the end of history (or of the world in its present state), the resurrection of the dead, the Last Judgment, and related matters. The term has been extended by historians of religions to cover similar themes and concepts in the religions of nonliterate peoples, ancient Mediterranean and Middle Eastern cultures, and Eastern civilizations.

Eschatological ideas and beliefs played a central role in the development of Judaism; the Kingship of God, "the end of days," "the world to come," the Messiah and the messianic era, the Day of Judgment, and the images of a perfected future were basic concerns in biblical (Old Testament) and rabbinic Judaism.

NATURE AND SIGNIFICANCE

In New Testament Christianity, history is viewed throughout in eschatological terms: the future of God has already begun with the appearance of Christ; the end of history is near; the end time is therefore filled with danger and salvation, faith and unfaith, Christ and Antichrist, and will be consummated through the resurrection of the dead, the judgment of the world, and its salvation through a new creation. Christianity, with this biblical heritage, has influenced many religions, revolutions, and civilizations through its orientation toward hope in the future. Biblical eschatological archetypes can be found in the various secular liberation movements leading up to the present day.

In the general history of religions, the term eschatology refers to *conceptions of the beyond* that express the destiny of man after his death (immortality of the soul, rebirth, resurrection, migration of the soul). These eschatological concepts stand in a mutual relationship with the experiences of men in the present world, the turning points of life, and the understanding of death. They often pose a contrast to the present experience of suffering within nature and society, within this whole "perverted world." Eschatological themes thrive particularly in crisis situations, whether they serve as consolations for those who hope for a better world or as the motives for revolutionary transformation of the world.

A distinction has often been made between individual (personal) eschatology and collective (social) eschatology. The eschatological expectations of either type, however, are as extensive as the respective believer's interest and involvement in life and his suffering from its miseries. These expectations can embrace individual souls; they can just as easily embrace a people or group, humanity, or the whole cosmos.

GENERAL CHARACTERISTICS

The theme of origins and last things. Because biblical eschatology is grounded in what are interpreted as uniquely occurring historical events (such as the Exodus of the Hebrews from Egypt in the 13th century BC), certain difficulties occur when the biblical concept of eschatology is translated into the eschatological framework of other religions. In other religions (especially Eastern religions and the religions of nonliterate peoples), cosmic representations of the eternal struggle between cosmos and chaos prevail. Therefore, a distinction must clearly be made between *mythical* eschatologies and *historical* eschatologies. The term mythical refers to the concept of the philosophically conceived truth of the human condition in relation to the realm of the sacred and the profane as defined in nontemporal terms and stories. The term historical, on the other hand, refers to the concept of the philosophically conceived truth of the human condition in relation to the realm of the sacred and the profane as defined in temporal terms and stories.

Mythical eschatologies

Mythical eschatologies emphasize the reproduction of the origin of the world at the end of the world. The end time repeats the primordial time; out of chaos (disorder) there arises anew the cosmos (order). At the origin there stands the cosmogony (creation of order) and the laws that govern the world and the pure order of things. Time is experienced as decay, degeneration, and guilt. Salvation, therefore, is found in a return of the origin or a return to the origin. All historical events are interpreted as representations of an eternal struggle in which the world order is defended against chaos. This struggle occurs as myth in the world of the gods and as history in the world of men. History thus becomes a cultic drama in which priests and kings play out the ritual roles foreordained to them.

The religious symbolism of mythical eschatology can be defined in terms of the "myth of the eternal return." This concept contains not only a cyclical view of history but also a cultic view of the annihilation of the horrors of history itself. In the ever-recurring cultic festivals, the lost time of history is regenerated and eternity is represented. Through the ritualistic repetition of all events in the creation of the cosmos, the impression of transience is proved to be a mere semblance. Everything basically remains in its place. In the framework of the myth of the eternal return, hope is inherent in memory. This basic structure is not limited to the great cultic religions; many messianic and revolutionary movements (such as the nativistic religious movements in Africa and Oceania, and sectarian movements in pre-1917 Russia) also exemplify it. Within a history that is generally regarded as evil, the saving future is depicted as a return to the primordial origin. In the terms of mythical eschatology, the meaning of history is found in a celebration of the eternity of the cosmos and the repeatability of the origin of the world.

Historical eschatology

Historical eschatology, on the contrary, is not grounded in a mythical primal happening but in historically datable events that are perceived as root experiences (past events that are narrative and paradigmatic in the present) and are regarded as fundamental for the progress of history. Biblical and biblically influenced eschatologies are grounded in such a view of historical experiences and are directed toward the historical future inaugurated by them. In this view, such experiences are never universal but always particular; they are not grounded in natural happenings but in historical election. Such events and experiences are not repeatable in cultic forms and rituals but are remembered through the telling of history and the relating of tradition. They do not abolish history; they rather inaugurate a new process (or new age) of history. They are events in which a *novum* (new or extraordinary thing) is perceived, that have a greater future than a beginning. Hope is thus grounded in historical remembrance but goes beyond what is remembered historically.

Because history is viewed as unrepeatable, the future of history is final. History is understood in this context not as the arena of the horrors of chaos but as the field of danger and salvation. The meaning of history is thus not found in its cultic abolishment (as in the case of mythical eschatologies) through the presence of eternity but in its future goal and its fulfillment. The divine or sacred is not experienced in the eternally recurring orders of nature and of the cosmos through ritualistic reenactments. Rather, God's freedom, faithfulness, and promises of the future are known and comprehended in the contingent and irreversible events of history. If here the future is greater than the beginning, hope at the end is more extensive than at the beginning.

Historical eschatologies are found in the faith of Israel and Judaism, which is grounded in the Exodus event (the

liberation of the Hebrews from Egypt in the 13th century BC) and which in the course of its historical experiences is more and more directed towards the expected revelation of the glory of God in all lands. Historical eschatologies are also found in the Christian faith, which is grounded in the history of Jesus and in the root experience of his resurrection from the dead. The hope of Christian faith is aimed at the Kingdom of Christ and the Kingdom of God, through which history is ended as well as fulfilled. In both cases the unique occurrence of a historical foundation event serves as a basis for the final goal of the long-awaited and hoped for future. A historically experienced *novum* opens up hope in a new creation that will be more than the reproduction of the primordial condition.

THE FORMS OF ESCHATOLOGY

In the sphere of historical eschatology, distinctions should be made between the hopes of messianism, millennialism, and apocalypticism. Messianic hopes are directed toward a king of the end time who will lead the people of God, now suffering and oppressed, into a better historical future. In political and nativistic messianism, visions of the vengeance and of the equalizing justice on the side of the oppressed are aimed at political and religious leaders. Always at work in these instances are inner and often local historical expectations of a certain fulfillment of history before the end of history. Apocalypticism should thus be distinguished from this point of view. Apocalypticism upholds the view that God will intervene in history on the side of a faithful minority and that the intervention will be accompanied by sudden, cataclysmic events. According to this view, "this world" cannot bear the "justice of God." Therefore, against what is perceived as the perverted world, the followers of apocalyptic views hope for the creation of a new world on the basis of God's righteousness. If this hope is universal, it is, nevertheless, not generally represented by a people but rather by individual holy men or, perhaps, by an ascetic community. Millenarian hope is directed toward the 1,000-year Kingdom of Christ and of his own people, in which the ones who are suffering now will rule over their enemies.

Messianism. The term messiah, derived from the Hebrew word *mashiah* ("anointed"), has been applied to a variety of redeemer figures, and many movements with a markedly eschatological or utopian-revolutionary character of message have been termed messianic. Though messianic movements have occurred throughout the world, they seem to be especially characteristic of the Jewish and Christian traditions. Hence, not only the word messiah but also other terms relating to the messianic type of phenomena are derived from biblical religion and from the history of Jewish and Christian beliefs—*e.g.*, "prophetic," "millenarian," and "chiliastic" movements—the last two terms referring to a 1,000-year reign of Christ and his saints before the final end of history. Moreover, the scientific study of messianic beliefs and movements—originating, as it did, in the Western theological and academic tradition—was directed mainly to phenomena occurring either in Christian history or in cultures exposed to Western colonial, missionary, and modernizing influences. These Western origins of messianic terms and concepts give discussions of the subject an almost unavoidable Judeo-Christian slant. Hence, many present-day sociologists and anthropologists have attempted to develop a more neutral terminology—*e.g.*, nativistic movements, religious movements of liberty and salvation, renewal movements, revitalization movements, crisis cults—but many of these terms emphasize incidental and adventitious aspects of the phenomenon and miss its essential features.

Apocalypticism. The term apocalypticism is generally restricted to eschatological views and movements in the West that focus on cryptic revelations about a sudden, dramatic, and cataclysmic intervention of God in history, the judgment of all men, the salvation of the faithful elect, and the eventual rule of the elect with God in a renewed heaven and earth. Western apocalypticism is based upon the archetypal apocalyptic work in the Judeo-Christian tradition, the Book of Daniel. Daniel is the only apocalyptic book to be admitted to the Old Testament canon, just as the Book of Revelation is the only apocalypse included in the canon of the New Testament. There are many noncanonical apocalyptic works from both Jewish and Christian authors, among them the three books of *Enoch*, the *Second Book of Esdras*, the *Ascension of Isaiah*, and the *Apocalypse of Peter*. All of the apocalyptic works written during the first efflorescence of millennialism, including the Book of Revelation, owe much of their shape and style to Daniel. This Old Testament book stands in the succession of the Jewish prophets and was apparently influenced by Iranian religious thought, such as the Zoroastrian concepts of the Last Judgment, the battle between good and evil involving both men and angels, and a punishment of fire for evildoers.

Millennialism. Millennialism (from the Latin word for 1,000) is a philosophy of history viewed from a Christian theological standpoint and a religious movement now associated with such modern Protestant sects as the Adventists, Jehovah's Witnesses, and certain segments of many Protestant denominations. There have been many millennial groups and individuals throughout church history. The term is derived from the imagery of the New Testament Book of Revelation (Rev. 20), in which the writer describes a vision of Satan being bound and thrown into a bottomless pit and of Christian martyrs being raised from the dead and reigning with Christ for 1,000 years. This 1,000-year period, known as the millennium, is viewed as a time during which man's yearnings for peace, freedom from evil, and the rule of righteousness upon earth are finally realized through the power of God.

As a branch of eschatology, millennialism is concerned with the earthly prospects of the human community. Not limiting itself to the prospects of the individual in this world and the next, millennialism attempts to answer in vivid imagery such questions as: What will be the final end of this world? Will mankind ever fulfill the agelong dream of dwelling in an earthly paradise or will all men be destroyed in a cataclysm of fire brought on by their own folly or God's judgment?

Millennialism is thus the cosmology (study of order) of eschatology, its chronology one of future events, comparable to the historical record of the past.

Millennialism is found within both Christian and other traditions. During the 20th century, anthropologists, historians, and sociologists explored the millennialist aspects of non-Western cultures, finding many striking similarities to the millennialism within the Judeo-Christian tradition. The millennial treatises produced by Jewish and Christian believers in the latter part of the Greco-Roman civilization—the Hellenistic period—particularly the books of Daniel and Revelation, provided the building materials from which the successive millennial structures were erected. In constant repetition the motifs, the leading characters, the symbols, and the chronologies of these works have arisen in the teaching of some prophet of the end of the world, each time taking on new significance from associations with contemporaneous events.

ESCHATOLOGICAL TERMINOLOGY

Eschatological language ordinarily uses two elements of style in conjunction with each other: the negation of the negative and the analogy of the future. Objective statements about the future that is not yet present are not possible in history. Such statements are possible only in the form of the negation of the negative in this life and this world. An example of this style may be found in Revelation 21:4: "And death shall be no more, neither shall there be mourning nor crying nor pain any more." Thus, the positive aspects of the eschatological future are circumscribed by the negative aspects of the present. If this future is to be meaningfully related to this life, however, this life, despite all its negativity, must also be presently capable of pointing toward or of foreshadowing the future life. Eschatological imagery and language, therefore, constantly use comparisons or analogies from everyday life (such as the several "the Kingdom of God is like . . ." analogies in the New Testament) and employ the hopes and anticipations of people and events from history in analogical ways.

The negation of the negative and the analogy of the future

A problem of eschatological language exists because of the necessary connection between negation and analogy. If negation is predominant, the tendency is towards apocalyptical and metaphysical dualism and towards mysticism. If analogy or foreshadowing of the future dominates eschatological language, the tendency is toward a one-sided belief in progress. In both cases the *novum* of eschatology becomes inexpressible. A hermeneutic (methodological interpretive principle) of eschatological traditions must verify the negation of the negative in face of the presently experienced negative and simultaneously seek the traces of the coming positive in the ambiguous history of liberations. There are always negative and positive signs of the future in history. "Where danger is, the saving also flourishes" (Hölderlin), but "where the saving draws near, danger also grows" (E. Bloch). Eschatology understands history as a growing crisis: the good provokes the evil, and the growing danger makes the action of redemption necessary. Authentic eschatology is neither world denying nor faith in progress but rather it can be seen as anticipation of freedom in the midst of slavery and of salvation in the midst of lostness and alienation.

ESCHATOLOGY IN NON-WESTERN RELIGIONS

Nonliterate cultures and nativistic movements. Eschatological motives must be understood in their religious and cultural contexts. According to the eschatological views of the people of the Andaman Islands, at the command of the god Puluga an earthquake will destroy the earth and the bridge of heaven; the souls and spirits of the dead will arise and be reunited. Then men will lead happy lives in power, without sickness, death, and marriage. Even the animals will appear again in their present form. The impatient spirits of the underworld are already now shaking the roots of the palm tree, which supports the earth, in order to bring about the end of this present world and the resurrection more quickly. The Semang pygmies in Malacca hold a somewhat different eschatological view:

The end of the order of the world

> In the beginning of the ages there was still absolutely nothing. Then Ja Pudeu [the highest being] blew with her mouth causing storms to rage over the earth. This was the means by which stars, water, trees, and everything came into being. At the end of the ages when all men shall have died, she will destroy everything with the same storms; a great flood will complete the destruction and the bones of men will swim together. Finally, the bones will rise.

The Australian aborigines claim that the end of the world will come when the moral world order legislated by the gods is no longer upright.

The Gabonese Pygmies in West Equatorial Africa believe that once Kmvum (the original man) lived with them faithfully. Then their guilt brought on the day of separation. He will come again, however, and bring back with him joy, abundance, and happiness. Among the Altaic Tatars of Central Asia there is an eschatological belief that Tengere Kaira Khān (the "graceful emperor of heaven"), who once lived on earth with men, will return at the end of the world in order to judge men according to their works. At his departure from earth he sent a mediator who remains faithful to him. At the end of the world the mediator will be victorious over evil. The Salish Indian tribes of the Pacific Northwest of North America believe that the creator god, before he vanished from the earth, promised the "elder" or "chief" his return at the end. When earth (a female figure) has become old, the coyote will return as the first sign of the world's end. This will be followed by the "chief" himself returning to earth. "After this there will no longer be a land of the spirits. All men will live together, the earth will receive her natural form and will live as a mother among her children. Then all things will be made right and happiness will reign."

Such mythical themes arranged around the origin–fall–return motif are experiencing a revival as primitive peoples suffer cultural shock in their encounters with Western civilization and Christianity. Many messianic movements of nonliterate cultures—even when antiwhite and anticolonialist—exhibit markedly Christian features both in the details of their symbolism as well as in their overall messianic ideology. Some messianic movements (*e.g.*, that of Simon Kimbangy in the former Belgian Congo from 1921, or that of Isaiah Shembe from 1911, among the South African Bantu, as also several movements in Brazil), in fact, appeared outwardly as Christian revivalist sects with an eschatological character. The movement of Simon Kimbangy has been admitted to the World Council of Churches as a member.

Nativistic messianic movements

A variety of names has been applied to these movements that emphasize various messianic characteristics. "Nativistic" movements expect salvation from a revival of native values and customs and a rejection of everything alien; *e.g.*, many of the North American Indian movements from the 17th century on, including the Pueblo Indian Revolt led by Popé in 1680; the anonymous Delaware prophet (1762) and Pontiac; the religious revival and revolt led by Tenskwatawa and Tecumseh in 1807; the Ghost Dance outbreaks of 1870 and subsequent years among Southwestern and Plains Indians. The messianic movements in Melanesia focussing on the arrival—in ships or airplanes—of "cargo" (*i.e.*, the coveted wealth and riches that symbolize power, well-being, and salvation) are referred to as cargo cults. Some anthropologists speak of "revitalization movements," whereas others emphasize the connection between acculturation and messianic movements. Since it is not acculturation as such that produces messianism but the crises and dislocations caused by certain forms of culture contact, many scholars prefer the more neutral and objective term "crisis cults." Since many movements are started or propagated by the activity and preaching of prophet-like leaders, they are also spoken of as "prophetic movements."

There is a tendency among modern anthropologists to consider primitive messianisms as forms of protonationalism in non-European and premodern societies. Though Christian influence and Christian symbols often play a major role in the crystallization of messianic ideologies, they are by no means their only source. The ideological starting point of a messianic movement can be supplied by native traditions and mythologies, by Christian ideas, or by motives that are born under the pressure of circumstance.

Religions of the East. Buddhism has four "noble truths"—the fact of human suffering, the understanding of the origin of suffering, the removal of the causes of suffering, and the path to the transcendence of suffering—and is partly therefore a religion of redemption. According to the Buddhist world view there is a macrocosm composed of innumerable worlds. In recompense for good and evil deeds, creatures are reborn in an unceasing process in the region that they deserve. Beyond all worlds is found Nirvāṇa ("bliss" or enlightenment), "the indescribable goal," whose attainment means redemption from the cycles of existence. Each one of the innumerable worlds passes through periods of destruction and recreation. There is no soul migration because there is no soul substance. Rather, each new existence is defined by *karman*, the deeds of the earlier existence. Only insofar as this is true can one speak of continuity in the reincarnations.

Buddhist and Hindu "eschatological" views

If anything at all in Buddhism can be considered as eschatological it is the yearning for an ultimate redemption from the cycle of rebirth and the final abolishment of the suffering bound up with it. In the religious community founded by the Buddha this yearning finds its peculiar way, the "eightfold path," on whose highest step occurs illumination or enlightenment. This illumination or "life beyond grief and woe" (Nirvāṇa) is a condition of eternal peace that cannot be conceived or described in ordinary terms. Rather, it comprehends even the worlds and their cycles themselves: "I do not know the end of suffering if we have not reached the end of the world" (Gautama, the Buddha).

According to Theravāda Buddhism, the individual believer must strive after redemption for himself through the exertion of his powers of being. At the centre of Mahāyāna Buddhism, on the contrary, stands the concept of the redemption of all living creatures which will occur through the sympathetic assistance of a redeemer figure.

In Hinduism the world of Brahman (the Universal Soul) is created by demiurges (creator beings) in egg-form and contains numerous zones and levels around the golden

world mountain Meru. It passes through a series of temporal cycles, and every temporal cycle ends with the destruction of the world followed by a new creation under a new demiurge. Man is now living in the dawn of the last, worst Kali *yuga* (age) of such a cycle. Through migration of the soul, man is drawn into the circle of the animals and plants. Rank and kind of birth are determined by the individual *karman* (acts and their consequences). The *karman*, which accompanies the soul and even has an effect on the destruction of the world, determines the following existence. After death, the soul returns to earth or it goes the "gods' way" (*devayāna*) of redemption. Redemption occurs when *karman* can no longer be produced, or it can happen through a divine act of grace that blots out the existing *karman*. Redemption is popularly viewed as entrance into the highest heaven of the god worshipped, where the redeemed one awaits a spiritual reflection of earthly joy. In modern Hinduism the soul that is identical with God is redeemed through a recognition of the organic wholeness that has vanished from consciousness because of the soul's imprisonment in matter. Self-recognition (*Ātman*) then leads to identity with the absolute being (Brahman). Redemption lies in the accomplishment, or rather recognition, of the *Ātman*-Brahman identity, for it already frees man from the chains of *karman* and *saṃsāra* (cycle of rebirths).

Buddhism and Hinduism do not have a historical eschatology. They rather emphasize an ultimate redemption from the cycles that have no beginning. Their redeemer figures are impersonal transparencies of the ultimate-universal.

Religions of ancient civilizations. In the religions of the West, there is a tendency to understand time as irreversible and therefore the end as occurring once and for all, as ultimate. The final judgment will be followed by the creation of a new and sacred world that is eternal. Origins of this kind of eschatological thinking are found in ancient Egypt in texts such as the "Shipwrecked Sailor" and the "Conversation between Atum and Osiris." The idea of an eschatological individual judgment of the dead is developed here in the strongest sense. Ancient Greek and Roman eschatological views depict a shadow life for the individual departed soul in Hades. Other than this focus on the individual, however, the cyclical concepts of periodic world destruction and world renewal are also found in these religions.

ESCHATOLOGY IN RELIGIONS OF THE WEST

Islām and Zoroastrianism. Islām is not a messianic religion and has no room for a saviour-messiah. Nevertheless, there gradually developed—probably under Christian influence—the notion of an eschatological restorer of the faith, identified as a descendant of the Prophet or as the returning ʿĪsā (*i.e.*, Jesus). He is usually referred to as the *mahdī*; *i.e.*, the "[divinely] guided one." After the appearance of ʿIsā, the last judgment will begin: the good will enter paradise; the evil will fall into hell. Heaven and hell possess various goals and steps of recompense for good and evil. The time before the end is viewed pessimistically: God himself will abandon the godless world. Ka'bah (the great pilgrimage sanctuary of the Muslim world) will vanish, the copies of the Qur'ān will become empty paper, and its words will disappear from memory. Then the end will draw near.

In Sunnī (traditional) Islām the whole subject is one of folklore rather than of dogmatic theology, though all orthodox Muslims believe in the coming of a final restorer of the faith. In times of crisis and of political or religious ferment, mahdistic expectations have increased and have given rise to many self-styled *mahdī*s, the best known of all being Muḥammad Aḥmad, the Mahdī of Sudan, who raised a revolt against the Egyptian administration in 1881 and after several spectacular victories established the mahdist state that existed until defeated by the English military leader Kitchener at Omdurman (Sudan) in 1898. In the Islāmic Shīʿah sect (which holds a belief in the transference of spiritual leadership through the family of ʿAlī, Muḥammad's cousin and son-in-law), the doctrine of the *mahdī* is an essential part of the creed. Among the Twelvers, the main Shīʿah group, the expected *mahdī* is believed to be the hidden 12th *imām*, or religious leader, who will reappear from his place of occultation. The notion of a *mahdī* also played a role in the foundation of new religions or Shīʿah sects—*e.g.*, the belief of the Druzes that the Egyptian caliph of the Fāṭimid dynasty al-Ḥākim (reigned 996–1021), who is thought to be the last prophet and divine incarnation, would return at the end of days (1,000 years after his appearance at the end of the 9th century AD) to establish his rule over the world. Other Islāmic-based messianic figures include the founder of the Indian Aḥmadīyah sect, Mirza Ghulam Ahmad, who in the late 19th century declared himself to be the Christ and the Mahdī; and the founder of the religion that subsequently became known as Bahā'ism, the Iranian Mirzā ʿAlī Moḥammad of Shīrāz, who proclaimed himself in 1844 to be the Bāb ("gate") on the 1,000th anniversary of the disappearance of the 12th *imām*.

Zoroastrianism is a religion with a thoroughly eschatological orientation: for it world history is a battlefield on which the forces of light and good fight the powers of darkness and evil. Though the notion of a personal saviour figure is not essential to the Zoroastrian system, it did nevertheless arise. The Iranian prophet Zoroaster's ministry (6th century BC) is said to have opened the last of the history of the world's four periods of 3,000 years each. He is followed, at intervals of 1,000 years, by three "saviours," considered to be posthumous sons of Zoroaster. The last of these, the *soshyans* (or *saoshyant*), will appear at the end of days, and God will entrust to him the task of the final rehabilitation of the world and the resurrection of the dead.

Judaism. *In ancient times.* The real inception of historical eschatologies stems from the Old Testament. Israel's faith in God there is rooted in the historical experience of the Exodus, and because of this experience of liberation it contains a hope in the guidance and the promises of God in history. The basic structure of this faith is found in the law of promise and fulfillment. The eschatology of the Old Testament is grounded in the identity of faith in God and hope in the future (Gen. 12:1ff.). It has its beginning in the promise of a "good and broad land, a land flowing with milk and honey" (Ex. 3:8). In the Pentateuch (first five books of the Old Testament) the promise is broadened to the increase of people and possessions, the blessing of God and the victorious presence of God (Gen. 49:8–12; Num. 23; Deut. 33:13–17; Num. 23:21). The history of the occupation of the land of Canaan (Palestine) and the victory of the Hebrews is to be understood as "realistic hope." Through the experiences of Israel's own disobedience to the laws and the will of God and defeats at the hands of its enemies, the concept of the "day of the Lord," which is to bring salvation and victory, came into existence. The happiness of the establishment of the Kingdom by David in the 10th century BC led to a hope in the future Messiah (Anointed One) of God from the house of David (II Sam. 7).

Concept of the "day of the Lord"

In the midst of the political catastrophes of the 8th century BC, the great prophets took up the concept of the "day of the Lord" and proclaimed it as a day of judgment (Amos 5:18) over the disobedient people and also over all other peoples. It was through such a process that the day of the Lord concept became the bearer of eschatological hopes. Isaiah also viewed salvation in an eschatological light as happening only after the universal judgment (Isa. 4:3; 6:13; 11:11; 37:31) and combined it with the presence of a messianic mediator of salvation (7–12).

In spite of the political destruction of Israel (8th century BC) and Judah (6th century BC) the prophetic hope kept Israel alive religiously. This prophetic hope was aimed primarily at a comprehensive and total new creation, a new heart, a new covenant (Jer. 31; Ezek. 36; Isa. 41; Isa. 51). Through the vicarious atonement of the servant of God (either the people of Israel or a messianic figure) this hope was to include not only Israel but also the Gentile world (Isa. 42:6; 49:6). The future of Israel is thus bound up with the future of all peoples and of the whole earth.

In the incipient apocalyptic views of the prophet Daniel (2 and 7), hope is transcendent. His apocalyptic eschato-

logical hope expects the "Kingdom of the Son of man" following the consummation of evil in the fourth and final kingdom of the world. Since that time, hope in a Messiah and hope in a Son of man have been bound to a kind of eschatology that unites the fulfillment of the history of Israel with the end of world history.

In the face of a threat to the existence of the Jewish faith and temple worship, a group of zealots revolted in 168 BC against the occupation forces of the Seleucid monarch of Syria, Antiochus IV Epiphanes (*c.* 215–163/164 BC) and against those of their Jewish countrymen who favoured reducing Judaism to the level of a hellenized Oriental (Greek and Syrian) cult. The author of Daniel constructed his work to give aid and comfort to the rebel cause, particularly to assure them that God was aiding them, that the end of their struggles was in sight, and that a new golden age was dawning. In a vision reputed to be seen by King Nebuchadrezzar, he depicted a series of four world monarchies, represented in one passage by parts of a giant statue and in another by mythological beasts, each empire embodying evil to a greater extent than the last. Man's empires will end with the fourth kingdom, which is crushed by a "stone. . . cut out by no human hand," symbolizing the fact that neither its destruction nor the ensuing order are natural developments from forces latent in history. A figure called the Son of man, however, will institute a fifth, entirely righteous, just, and eternal kingdom.

Visions of the ages of the world

As in the Jewish prophetic tradition that preceded it, Daniel made predictions about the future, but, unlike the predictions of a prophet such as Jeremiah (late 7th to early 6th century BC), the outcome anticipated by the prophet was not the virtually inevitable product of antecedent forces but a total reversal of what might seem to be the likely outcome if God were not to intervene. The reversal of worldly expectations through a violent supernatural intervention in the course of history is one of the most characteristic features of apocalypticism and stands quite in contrast to the older prophetic style. Also essential to Daniel and subsequent apocalypticism is the immediacy of the message and the imminence of the deliverance that is promised—the promise of salvation now. Descriptions of this imminent salvation of cosmic proportions included vivid representations of historical figures who depicted the growth of evil and decline of goodness from past time down to the present, when all wickedness came into terrifying focus.

To these significant emphases in Daniel's apocalypse—the imminent and supernatural intervention of God in man's history and the reversal of the heretofore irresistible progress of evil and declension of good—might be added other characteristics that have proved to be influential. Numerology, mythological figures, and angelology, which have continued to play such a large part in millennial movements, were probably introduced as a result of the influence of Iranian thought. Other characteristics of Daniel, such as its pseudonymous authorship and the emphasis upon the esoteric, mysterious quality of the truths discussed, were probably due to the unique problems faced by the author in presenting these views to a 2nd-century-BC audience.

In Hellenistic Judaism. In the period of Seleucid (Syrian Greek dynasty ruling Palestine *c.* 200–165 BC) and later Roman and Byzantine (63 BC–AD 638) rule and oppression, the expectation of a personal messiah acquired increasing prominence and became the centre of a number of other eschatological concepts held by different groups in different combinations and with varying emphases. The Qumrān sect, a Jewish monastic group known in modern times for its preservation of the Dead Sea Scrolls, held a doctrine—found also in later Jewish sects—of a messianic pair: a priestly messiah of the House of Aaron (the brother of Moses) and a royal messiah of the House of David. This messianic detail, incidentally, shows that these "anointed ones" were not thought of as saviours—as in later Christian thought—but rather as ideal leaders presiding over an ideal, divinely-willed, and "messianic" socioreligious order. The "son of David" messianism, with its political implications, was overshadowed by apocalyptic notions of a more mystical and mythological character. Thus it was believed that a heavenly being called the "son of man" (the term is derived from Daniel 7:13) would descend to save his people (*e.g.*, as in the apocryphal books of Enoch). The messianic ferment of the period, attested by contemporary Jewish-Hellenistic literature, is also vividly reflected in the New Testament.

The destruction of the Temple at Jerusalem by the Romans (AD 70), exile, persecution, and suffering only intensified Jewish messianism, which continued to develop theoretically in theological and semimythological speculations and to express itself practically in messianic movements. In popular apocalyptic literature another messianic figure gained some prominence: the warrior-messiah of the House of Joseph (or Ephraim) who would precede the triumphant messiah of the House of David—but would himself fall in the battle against Gog and Magog, two legendary powers under Satan and opposed to the people of God (Ezek. 38:2; Rev. 20:8). The notion seems to have developed toward the end of the 2nd century, after the failure of the last revolt against the Romans (AD 132–135), led by Bar Kokhba, who was hailed as the messiah, but it is connected with a more basic notion of apocalyptic messianism; that is, the belief that the messianic advent is preceded by suffering and catastrophe. In some versions of apocalyptic messianism, the notion of a messianic age merges with that of an end of days and last judgment: the "new heaven and new earth" are ushered in amid destruction and catastrophe.

Apocalyptic messianism

In medieval and modern Judaism. Messianic faith tended to develop into mass enthusiasm, frequently fed by calculations based on the Book of Daniel and other biblical passages. Almost every generation had its messianic precursors and pretenders; *e.g.*, Abū ʿĪsā al-Iṣfahānī and his disciple Yudghan in 8th-century and David Alroy in 12th-century Persia; the propagandists of the messianic agitation in the Jewries of western Europe in the 11th and 12th centuries; and—perhaps the most notorious of all—the 17th-century pseudomessiah Shabbetai Tzevi (Sabbatai Zevi) of Smyrna. Belief in, and fervent expectation of, the messiah became firmly established tenets of Judaism and are included among the great Jewish medieval philosopher Maimonides' Thirteen Articles of Faith. There was much variety in the elaboration of the doctrine—from the early apocalyptic visionaries and later Kabbalistic (Jewish esoteric) mystics at one end of the scale to the rationalist theologians on the other. The latter (including Maimonides) emphasized the unmiraculous nature of the messianic age.

Modernist movements in Judaism tended to maintain the traditional faith in an ultimately redeemed world and a messianic future for mankind, without insisting on a personal messiah figure. Judaism undoubtedly owes its survival, to a considerable extent, to its steadfast faith in the messianic promise and future. Jewish messianism, in spite of its spiritual and mystical connotations, never relinquished its this-worldly orientation and its understanding of the messianic order in historical, social, and political terms. Hence, many writers consider the participation of Jews in so many secular reform, liberation, and revolutionary movements as a secularized version of traditional Jewish messianism. Similarly, the ideology of Zionism, as a movement for Jewish national emancipation and liberation, is not devoid of messianic features.

Individual eschatology emerges only on the periphery of the Old Testament. Amazingly, there were in Israel no known death cults and no vivid conceptions of life after death. The late expectation of the resurrection from the dead to judgment (Dan. 12:2) is not a yearning for salvation but hope in the victorious righteousness of God. Rabbinical messianism continued this same line of thought.

Christianity. *In the New Testament period.* The preaching and ministry of Jesus of Nazareth and the activities of his followers in the 1st century AD can be properly understood only in the context of contemporaneous Jewish eschatological beliefs. Though the precise nature of Jesus' beliefs about himself and about the nature of the "messianic" task that he attributed to himself are still a matter of scholarly controversy, there is little doubt that already at an early date his followers saw in him the promised "anointed one" (Greek *christos*, whence the En-

Messianic conceptions of Jesus

glish Christ) of the Lord, the son of David. This view is evident in the Gospel accounts that attempt to trace the ancestry of Jesus back to David, evidently for the purpose of legitimizing his messianic status. According to Luke 2:11 his messiahship was also proclaimed by angels at his birth. Jesus himself seems to have rejected the term—possibly because of its political implications—in favour of other eschatological titles (*e.g.*, the "Son of Man"), but the early community of his followers, believing, as they did, in his Resurrection after the crucifixion, evidently held this term to be expressive more than any other of the role and function that they attributed to their master and "Lord" (Greek *kyrios*). In due course the title ("Jesus, the Christ") became synonymous with the proper name, and the word Christ was used by believers as the name of the risen Jesus (*cf.* Gal. 1:6; Heb. 9:11).

With the adoption of the Greek word "Christ" by the church of the Gentiles (non-Jewish believers), the nationalist and political implications of the term "messiah" vanished altogether in Christianity, and the "Son of David" and the "Son of man" motifs, to which subsequently was added that of the "suffering Servant" (Isa. 52–53), could merge in a politically neutral and religiously original messianic conception. Subsequently, the doctrine of the messiahship of Jesus (*i.e.*, Christology) also had to take into account other features of evolving Christian dogma (the Messiah as the Son of God; the Trinity, of God the Father, Son, and Holy Spirit; the incarnation of the Word), and thus came to assert that Jesus as the Messiah, Saviour, and Redeemer was essentially divine. In due course the concept of salvation was radically spiritualized, and the Messiah, through his sacrificial death, was viewed as having delivered man from his bondage to sin and having restored him to communion with God. Meanwhile, Christians asserted that the present world order would provisionally continue until the Second Coming (the Parousia) of Christ in power and glory to judge the living and the dead.

The early Christians held this Second Coming to be imminent, but as time went on this particular expectation shifted to the eschatological horizon. In the centuries immediately following the writing of Daniel, the apocalyptic world view had significantly influenced Jewish culture; the audiences whom Jesus addressed were acquainted with it; and the early Christian Church embraced the apocalyptic world view. The Apostle Paul frequently expressed apocalyptic expectations (I Thess. 4), and Mark 13, a passage often called "the little apocalypse," reflects the apocalyptic expectations of the Roman church at about AD 70.

The Christian Church in the 1st century wrestled with a difficult problem. Jesus had promised the inauguration of a new age, the Kingdom of God, and yet life proceeded after his death in much the same way that it had before his birth, with the exception that Christian believers suffered severe persecution for their faith. The primitive church solved this problem through the paradox of the Second Coming of Christ: Christ has come and is coming again. They believed that the new age had dawned but would not be fully revealed until Christ's Second Coming in glory.

The Book of Revelation

Like the Book of Daniel, the Revelation to John or Revelation was composed during a period of persecution. It was probably written during the last decade of the 1st century AD, and it reflects the persecutions beginning under the emperor Nero (AD 37–68), who seems to be portrayed as the Antichrist—the beast whose symbolic number is 666 (Rev. 13). After addressing letters to churches of Asia Minor, the author depicted his vision of a series of judgments—seven seals opened, seven trumpets blown, seven bowls poured out. The writer directed his attack against the Roman Empire, referred to cryptically as Babylon and as the great harlot. Christ was described as the executor of God's judgment, appearing not as the man Jesus but as an omnipotent king riding upon a white horse with eyes like a flame of fire and a mouth like a sharp sword "with which to smite the nations" (Rev. 19). In the Book of Revelation the assimilation of Jewish apocalypticism to Christianity was completed. Daniel's Son of man was replaced by Christ; many of the numerological formulas were repeated; and the dualistic universe of good and evil, Christ and Antichrist, was provided with a new and unforgettable set of characters. The essence of the apocalypse in Revelation remained what it had been in Daniel: the immediate, direct aid of God was to be momentarily expected, accomplishing the dramatic reversal of history that the believers' present desperate state demanded.

Apocalyptic symbolism

In the early church. During the first hundred years of Christian history, this form of millenarianism, or chiliasm (from the Greek word for 1,000), was commonly taught and accepted within the church. Persecution of the church was intermittent, however, and apocalyptic zeal flagged without the pressure of opposition. Christian missionaries succeeded in converting large numbers of Roman citizens, and some of the antagonism toward the empire was dissipated. The appeal of millenarian thought was further limited by its association with the heresy of Montanism. In characteristic apocalyptic fashion, Montanus, the founder of the movement, was fascinated with the idea of dividing past and future into units of prophetic calculation. In AD 156, according to the 4th-century Christian antiheretical writer Epiphanius, Montanus declared himself the prophet of a third testament, a new age of the Holy Spirit. Phrygia in Asia Minor became the centre of this ecstatic and ascetic movement whose leaders claimed divine inspiration for their visions and utterances, the main theme of which was the imminent Second Coming of Christ. This concept of the third age, the new day of the spirit of God, has been one of the most consistently repeated features of millenarian history, reappearing, for example, in Joachim of Fiore's philosophy of history during the 12th century, in views of the 17th-century Quakers, and in the apocalyptic speculations of the Seventh-day Adventists of the 19th and 20th centuries. When persecution of Christians was renewed late in the 2nd century, Montanism began to appeal outside Asia Minor and found converts throughout the Roman Empire, including Tertullian, a North African lawyer and theologian. The church survived this persecution, however, and Montanism was stigmatized as a heresy.

The age of the Holy Spirit

The influence of Greek thought upon Christian theology undermined the millenarian world view in another, possibly more significant, manner. In the theology of the great 3rd-century Alexandrian Christian thinker Origen, the focus was not upon the manifestation of the kingdom within this world but within the soul of the believer, a significant shift of interest away from the historical toward the metaphysical, or the spiritual. The association of apocalyptic millenarianism with the Montanist heresy, the growing influence of Greek thought upon Christian theology, and the conversion of Constantine the Great and adoption of Christianity as the favoured religion of the empire—all combined to discredit millenarianism for centuries.

The views of Augustine. In the new age of the church triumphant—*i.e.*, when Christianity became the accepted religion of the Roman Empire—Augustine (354–430), bishop of Hippo, gave definitive expression to the view that was to dominate Western civilization through the Reformation. In his *City of God,* a philosophy of history, Augustine viewed the world as eternally divided between the City of the World and the City of God. All men owe allegiance to one or the other of these cities and will ultimately share the fate of that community. The City of the World is ruled by Satan, the prince of this world. He and all who pay homage to his city will suffer eternal punishment. The City of God is represented in the church, and for the church God has ordained salvation from the persecution of the City of the World and eternal bliss in the courts of heaven. Much of this conception is reminiscent of the apocalyptic world view, but the views of Augustine also contained distinct differences.

The City of the World and the City of God

The dualism represented in apocalypticism is reflected with equal intensity in Augustine's two cities. Furthermore, Augustine remained as pessimistic as any millenarian about the future of the City of the World and the prospect of progress in this world. After his conversion to Christianity, Augustine, a former *bon vivant,* consistently favoured a world-denying and ascetic style of life. In fact, his disillusionment with worldly values was more thorough than that of the millenarians, for he rejected as carnal any expectations of a renewed and purified world that the believers could expect to enjoy. In this respect

he differed sharply with the apocalyptic tradition. The millenarian, in contrast to Augustine, had no quarrel with the world as such except that he had found it controlled by his enemies. The millenarian believed that when the imminently expected saviour had defeated these foes, the righteous would share in an earthly paradise, a land of physical, not spiritual, benefits.

The literalistic descriptions of the judgments that were predicted for the wicked and the bliss foretold for the righteous found in such apocalyptic works as the Book of Revelation were interpreted allegorically by Augustine. He expected that ultimately the history of this world would end, but for him the millennium had become a spiritual state into which the church collectively had entered at Pentecost—the time of the reception of the Holy Spirit by Christ's disciples soon after his Resurrection—and which the individual Christian might already enjoy through mystical communion with God. In contrast to the apocalypticist's focus upon the contemporary world, Augustine, though just as influenced by his own cultural milieu, responded with a millennial eschatology that seemed almost oblivious of time. As far as the struggle with evil in this world is concerned, Augustine surrendered and abandoned the field. No imminent supernatural intervention in history was expected, and no dramatic reversal of the tide of battle was anticipated. Augustine taught what has been referred to as "realized" eschatology. For him the battle had already been fought on the spiritual ground that really mattered. God had triumphed. Satan has been reduced to lordship in this world. In the present age the City of the World and the City of God have been forced to coexist. Eventually, even that small patrimony that Satan claimed would be taken from him, and God would become triumphant.

Realized eschatology

Medieval and Reformation millennialism. Augustine's allegorical millennialism became the official doctrine of the church, and apocalypticism went underground. During the late Middle Ages and the Reformation, millenarian views were frequently voiced, most often by rebels and radicals. The extreme wing of the Bohemian Hussite movement, known as the Taborites, sought to establish the Kingdom of God by force of arms. The left-wing Protestant Anabaptists as well as the Bohemian and Moravian Brethren were millenarians. The great Peasants' War in Germany (1524–25), in which the radical reformer Thomas Müntzer and the radical Zwickau prophets took a leading part, and the Anabaptist "Kingdom of God" in the German city of Münster (1534–35)—ruled over by the fanatical John of Leiden—are examples of millenarian-apocalyptic movements or of social movements with a messianic dimension.

In England, the Independents (those who separated themselves from the Church of England) thought of ushering in the Kingdom of God, and groups such as the Fifth Monarchy Men believed that revolution was necessary to prepare the way for the reign of Christ and his saints. The revolutionary Puritan leader Oliver Cromwell's (1599–1658) sober common sense and his dissolution of the so-called Parliament of Saints prevented apocalyptic enthusiasm from dominating the Commonwealth. The millenarian element also was strong in 17th- and 18th-century German Pietism, and it played a major role in the doctrines of many sects that arose in the 19th century in the United States and Great Britain (*e.g.,* Irvingites, Mormons, Adventists, Jehovah's Witnesses, Christadelphians, and others). Many of these sects, however, are more correctly described as entertaining messianic expectations than as actual messianic movements.

Apart from these dissidents, the doctrine of Augustine remained unchallenged until the 17th century. The Protestant Reformers of the Lutheran, Calvinist, and Anglican traditions were not apocalypticists but remained firmly attached to the views of Augustine, for whose theology they felt a particular affinity. Many of the allusions of the Book of Revelation were viewed in a distinctly Protestant perspective by the Reformers—the allusions to Rome as the great harlot and as Babylon being transferred to the Roman church, and the pope being identified as the beast. Each of the three main Protestant traditions of 16th-century Europe, however, found support from the secular authorities in Saxony, Switzerland, and England and remained in the same position vis-à-vis the state as had the medieval church. The apocalyptics within medieval Christendom, as well as in the 16th-century Reformation, were those who believed that their only help was the Lord and for whom persecution was a reality and destruction an imminent threat.

The Augustinian millennial world view, though it survived the Reformation, did not survive the intellectual revolution of the 17th century. Behind the development of science lay a profound reorientation of Western thought that involved, in the first place, the rehabilitation of nature. A part of Augustine's rejection of the world stemmed from the frustration felt by his generation in attempting to cope with the natural and social history of its time. By 1600 Europeans had gained confidence in their own abilities. Such philosophers as Francis Bacon announced the dawn of a new day and attacked the Augustinian reluctance to see anything but the work of the devil in attempts to control or understand natural processes. Secondly, European intellectuals were becoming far more interested in measurement and quantification. Allegory fell into disrepute when the medieval interpretation of the nature of the heavenly bodies was proved to be erroneous by the facts discovered by the use of the telescope. A new concern with calculation and literalism spread to biblical scholarship and resulted in the creation of the third type of millennialism found in the Christian tradition—progressive millennialism.

Progressive millennialism

Early progressive millennialism. Joseph Mead (Mede), a 17th-century Anglican biblical scholar, was the pioneer in the movement. Ignoring the allegorical interpretation long associated with the book, Mead took a fresh look at the text of Revelation. He concluded that the Scriptures held the promise of a literal Kingdom of God. The work of redemption, he concluded, would be completed within human history on the stage of this world. The Book of Revelation itself seemed to contain a historical record of the progress of that Kingdom, and scholars other than Mead soon were speculating where in the prophetic timetable the modern millennialist might locate himself. Thus far, progressive millennialism appeared to be identical with the apocalyptic millenarianism of the early church, but there the similarity ended. The Kingdom would not be brought into being through any dramatic reversal of the historical process, nor did the progressive millennialists believe that the Second Advent of Christ would occur in order to rescue them from destruction. History did not need reversing for these early Enlightenment Christians (those who emphasized reason). They thought of the record of the past as the story of victory over evil and the conquest of Satan. They rejected the fundamental assumptions of the apocalypticist—*i.e.,* that victory would be snatched from the jaws of defeat only by a miraculous deliverance. For them it seemed that the progress of history had been continuously upward, that the Kingdom of God was coming ever closer, and that it would arrive, not without struggle, but on the basis of the same kind of effort that had always triumphed in the past.

Millennialist optimism

In the 18th century the teachings of the progressive millennialists became dominant in many Protestant churches. The Anglican polemicist and commentator Daniel Whitby (1638–1726), in his *Paraphrase and Commentary on the New Testament* (1703), provided such convincing support to the position that he has often been credited with creating it. In America interest in the millennium had not been lacking among Puritan scholars, but it was the great revivalist Jonathan Edwards (1703–58) who first adopted progressive millennialism, giving detailed exposition of his views in his uncompleted *History of the Work of Redemption.* Edwards saw significance for millennialism in the discovery and settlement of the New World, and he anticipated the establishment of Christ's kingdom sometime near the end of the 20th century.

Later progressive millennialism. The association of the millennium with the role of the United States proved to be a volatile 19th-century mixture in the hands of Protestant ministers, and for much of that period millennialism

fed the fires of nationalism and Manifest Destiny. In a typical utterance, a leading Presbyterian minister of the 1840s, Samuel H. Cox, told an English audience that, "in America, the state of society is without parallel in universal history.... I really believe that God has got America within anchorage, and that upon that arena, He intends to display his prodigies for the millennium." The late 19th-century movement known as the Social Gospel, dedicated as it was to establishing the Kingdom of God here and now, manifested most clearly the continuing influence of progressive millennialism.

Because the advocates of optimistic millennialism were confident of the ultimate triumph of their cause, it must not be assumed that they took evil lightly. They thought of God's Kingdom as advancing, as Jonathan Edwards argued, but not without destruction. Though they were not apocalyptic, their view of history included the cataclysmic. In the American Civil War, for example, the antislavery writer Julia Ward Howe, in "The Battle Hymn of the Republic," described God's truth as "marching on." In Pres. Woodrow Wilson's crusade to make the world "safe for democracy" by the entry of the United States into World War I (1914–18), one can see the same idea barely disguised. According to the progressive millennialists, Christ's Second Advent would occur at the close of the millennium as its crowning event, and, as a result, their position has frequently been called postmillennialism.

ESCHATOLOGY IN MODERN TIMES

Western civilization, even in its modern secularized forms, is heir to a long tradition of Christian patterns of thought and sensibility. Thus, it is not surprising that many movements of social reform as well as ideologies regarding an ideal future should bear traces—conscious or unconscious—of Christian influence. Both the 18th- and 19th-century Enlightenment and the Romantic versions of the idea of the progress of humanity to an ideal state of peace and harmony betray their descent from messianic-millenarian beliefs. The 18th-century German philosopher Immanuel Kant, when speaking of the ideal state of eternal peace, describes this concept as a "philosophical chiliasm." The indebtedness of presocialist, utopian thinkers—such as the French social reformer Henri de Saint-Simon, the English reformer Robert Owen, and the French reformer Charles Fourier—to Christian millenarianism was recognized by Karl Marx and Friedrich Engels, who, in their *Communist Manifesto* (1848), contemptuously referred to the utopias of these writers as "duodecimo editions of the New Jerusalem." Some early socialist movements, including Christian socialism, exhibited messianic features. Marxist Communism, in spite of its explicit atheism and dogmatic materialism, has a markedly messianic structure and message.

Analogies of Marxist Communism with Christian messianism

Some of the analogies between Marxism and traditional Christian eschatology have been described, in a slightly ironical vein, by the English philosopher Bertrand Russell, who contends that Marx adapted the Jewish messianic pattern of history to socialism in the same way that the philosopher-theologian St. Augustine (AD 354–430) adapted it to Christianity. According to Russell, the materialistic dialectic that governs historical development corresponds—in the Marxist scheme—to the biblical God, the proletariat to the elect, the Communist Party to the church, the revolution to the Second Coming, and the Communist commonwealth to the millennium.

Whether or not Socialism and Communism, as well as certain national liberation movements, are described as secularized messianism, pseudomessianism, "substitute" messianism, and the like, is partly a matter of semantics, partly an attempt to use evaluative instead of descriptive language. The differences between secular ideologies and traditional messianic expectations are obvious. The similarities are founded on actual historic contacts and derivation (as in the history of reform and revolutionary movements in the West as well as of liberation movements in countries colonized by the West), and also on the fact that they are variations of the same social dynamisms and of a basic myth, expressing in powerful imagery certain elemental human experiences and aspirations.

Since the exegetical (interpretive) works of Johannes Weiss and Albert Schweitzer around 1900 (school of "consistent eschatology") and dialectic theology (Karl Barth, Rudolf Bultmann), eschatology has again become a principal theme of academic Christian theology. The crises in the Western countries have led to a renewed activization of eschatological hopes. In church struggles, this was expressed in terms of distinctions between Christianity as a state religion and congregations with eschatological orientations. On its margins, Western civilization contains a series of mystical and apocalyptical "anticultures." Initial attempts to combine eschatology and philosophy, hope, and social practice, and thus overcome the difference between the church and the sects, as well as the church and the modern age, are found in Ernst Bloch's philosophy of hope (*Das Prinzip der Hoffnung*, 1959), the writings of P. Teilhard de Chardin, and in the "theology of hope" (J. Moltmann, W. Pannenberg, H. Cox, L. Dewart, etc.). Eschatology is one of the main focuses of Christianity. Therefore, its most important theological decisions about theory and practice must take eschatological concerns seriously, as seriously as the many and varied revolutionary groups (both religious and secular) have done in the 20th century. (J.D.M./R.J.Z.W./E.R.S./Ed.)

Angels and demons

Throughout the history of religions, varying kinds and degrees of beliefs have existed in various spiritual beings, powers, and principles that mediate between the realm of the sacred or holy—*i.e.*, the transcendent realm—and the profane realm of time, space, and cause and effect. Such spiritual beings when regarded as benevolent are usually called angels in Western religions; those viewed as malevolent are termed demons. In other religions—Eastern, ancient, and those of nonliterate cultures—such intermediate beings are less categorical, for they may be benevolent in some circumstances and malevolent in others.

NATURE AND SIGNIFICANCE

The meaning of angels in functional terms

Angels. The term angel, which is derived from the Greek word *angelos*, is the equivalent of the Hebrew word *mal'akh*, meaning "messenger." The literal meaning of the word angel thus points more toward the function or status of such beings in a cosmic hierarchy rather than toward connotations of essence or nature, which have been prominent in popular piety, especially in Western religions. Thus, angels have their significance primarily in what they do rather than in what they are. Whatever essence or inherent nature they possess is in terms of their relationship to their source (God, or the ultimate being). Because of the Western iconography (the system of image symbols) of angels, however, they have been granted essential identities that often surpass their functional relationships to the sacred or holy and their performative relationships to the profane world. In other words, popular piety, feeding on graphic and symbolic representations of angels, has to some extent posited semidivine or even divine status to angelic figures. Though such occurrences are not usually sanctioned doctrinally or theologically, some angelic figures, such as Mithra (a Persian god who in Zoroastrianism became an angelic mediator between heaven and earth and judge and preserver of the created world), have achieved semidivine or divine status with their own cults.

In Zoroastrianism there was a belief in the *amesha spentas*, or the holy or bounteous immortals, who were functional aspects or entities of Ahura Mazdā, the Wise Lord. One of the *amesha spentas*, Vohu Manah (Good Mind), revealed to the Iranian prophet Zoroaster (6th century BC) the true God, his nature, and a kind of ethical covenant, which man may accept and obey or reject and disobey. In a similar manner, about 1,200 years later, the angel Gabriel (Man of God) revealed to the Arabian prophet Muḥammad (5th–6th century AD) the Qur'ān (the Islāmic scriptures) and the true God (Allāh), his oneness, and the ethical and cultic requirements of Islām. The epithets used to describe Gabriel, the messenger of God—"the spirit of holiness" and "the faithful spirit"—are similar to those

applied to the *amesha spentas* of Zoroastrianism and the third Person of the Trinity (Father, Son, and Holy Spirit) in Christianity. In these monotheistic religions (though Zoroastrianism later became dualistic) as also in Judaism, the functional characteristics of angels are more clearly enunciated than their ontological (or nature of Being) characteristics—except in the many instances in which popular piety and legend have glossed over the functional aspects.

Various religions, including those of nonliterate cultures, have beliefs in intermediary beings between the sacred and profane realms, but the belief is most fully elaborated in religions of the West.

Changes and variations in the meaning of the term demon

Demons. The term demon is derived from the Greek word *daimōn,* which means a "supernatural being" or "spirit." Though it has commonly been associated with an evil or malevolent spirit, the term originally meant a spiritual being that influenced a person's character. An *agathos daimōn* ("good spirit"), for example, was benevolent in its relationship to men. The Greek philosopher Socrates, for example, spoke of his *daimōn* as a spirit that inspired him to seek and speak the truth. The term gradually was applied to the lesser spirits of the supernatural realm who exerted pressures on men to perform actions that were not conducive to their well-being. The dominant interpretation has been weighted in favour of malevolence and that which forbodes evil, misfortune, and mischief.

In religions of nonliterate peoples, spiritual beings may be viewed as either malevolent or benevolent according to the circumstances facing the individual or community. Thus, the usual classification that places demons among malevolent beings is not totally applicable in reference to these religions.

The positions of spiritual beings or entities viewed as benevolent or malevolent may, in the course of time be reversed. Such has been the case in the ancient Indo-Iranian religion, from which evolved early Zoroastrianism and the early Hinduism reflected in the Vedas (ancient Aryan hymns). In Zoroastrianism the *daevas* were viewed as malevolent beings, but their counterparts, the *devas* in ancient Hinduism, were viewed as gods. The *ahuras* of Zoroastrianism were good "lords," but in Hinduism their counterparts, the *asuras,* were transformed into evil lords. In a similar manner, Satan, the prosecutor of men in the court of God's justice in the Old Testament book of Job, became the chief antagonist of Christ in Christianity and of man in Islām. Many similar transformations indicate that the sharp distinctions made between angels as benevolent and demons as malevolent may be too simplistic, however helpful such designations may be as indicators of the general functions of such spiritual beings.

CELESTIAL AND NONCELESTIAL FORMS: RELATIONSHIPS OF BELIEFS IN ANGELS AND DEMONS TO VIEWS OF THE COSMOS

Man's concern with ways of relating to the cosmos

Because man is a being much concerned with boundaries—*i.e.,* what makes him different from other animate beings, what makes his community (and thus his world) different from other communities (and other worlds)—his view of the cosmos has influenced his understanding of what are called angels and demons. The cosmos may be viewed as monistic, as in Hinduism, in which the cosmos is regarded as wholly sacred or as participating in a single divine principle (Brahman, or Being itself). The cosmos may also be viewed as dualistic, as in Gnosticism (an esoteric religious dualistic belief system, often regarded as a Christian heretical movement, that flourished in the Greco-Roman world in the 1st and 2nd centuries AD), in which the world of matter was generally regarded as evil and the realm of the spirit as good. A third view of the cosmos, generally found in the monotheistic religions of Judaism, Zoroastrianism, Christianity, and Islām, centred on a tripartite universe: celestial, terrestrial, and subterrestrial. This third view has influenced Western man's concepts of angels and demons as well as his scientific and metaphysical concepts.

Relationship to views of a tripartite cosmos. In the biblical, Hellenistic (Greco-Roman cultural), and Islāmic worlds of thought, the terrestrial realm was a world in which man was limited by the factors of time, space, and cause and effect. The celestial realm, generally composed of seven heavens or spheres dominated by the seven then-known planets, was the realm of the divine and the spiritual. The subterrestrial realm was the area of chaos and the spiritual powers of darkness. At the highest level of the celestial sphere was the ultimate of the sacred or holy: *e.g.,* Yahweh, the God of Judaism, whose name was so holy it should not even be spoken; Bythos, the unknowable beginning beyond beginnings of Gnosticism; the heavenly Father of Christianity, known through his Logos (the divine Word, or Reason, Jesus Christ); and Allāh, the powerful, the almighty, and the sublime God of Islām.

The role of angels as celestial beings

In order to reveal the purpose and destiny of man—the highest being of the terrestrial realm—the ultimate of the celestial sphere enabled man, according to such views, to come to a knowledge of who he is, what is his origin, and what is his destiny through celestial messengers—angels. The message, or revelation, was usually focussed on the identity of the source of the revelation—*i.e.,* the ultimate being—and on the destiny of man according to his response. Because of a cosmic rift in the heavenly sphere prior to the creation of the world or the announcement of the revelation, angels, depending on their relationship to the Creator, might attempt to deceive man with a false revelation or to reveal the truth about man's true nature (or identity), origin, and destiny. Angels who attempted to pervert the message of the ultimate celestial being in order to confuse man's understanding of his present boundary situation as a terrestrial being or his destiny as a suprater-restrial being—though not always termed demons—are malevolent in function. Included among such malevolent angels are the devil of Christianity and Judaism or Iblīs (the Devil) of Islām, who, in the form of a serpent in the biblical story of the Garden of Eden—according to later interpretations of the story—attempted to disrupt man's understanding of his creaturely boundaries, or limitations. He did this by tempting man to eat the fruit of the tree of knowledge of good and evil so that he might become like God (or the divine beings of the heavenly court). In Zoroastrianism, the Evil Spirit (Angra Mainyu, later Ahriman) attempted—through subservient spirits such as Evil Mind, the Lie, and Pride—to deceive terrestrial man so that he would choose a destiny that was subterrestrial—punishment in a chasm of fire.

In the aftermath of the 16th-century Copernican revolution (based on the theories of the Polish astronomer Copernicus), in which man's view of the cosmos was radically altered—*i.e.,* the Earth was no longer seen as the centre of the cosmos but, instead, merely as a planet of a solar system that is a very small part of a galaxy in an apparently infinite universe—the concepts of angels and demons no longer seemed appropriate. The tripartite cosmos—heaven above, Earth in the middle, and hell below—appeared to be an anachronism.

Influence of psychology on angelology and demonology

With the emergence of modern Western psychology and psychoanalytical studies in the 19th and 20th centuries, however, the underlying principles of beliefs in angels and demons have taken on new meanings. Many Christian theologians have found some of the concepts of psychoanalysis helpful in reinterpreting the meanings underlying primitive and traditional beliefs in angels and demons. The tripartite cosmos was re-mythologized into a tripartite structure of the personality—the superego (the restrictive social regulations that enable man to live as a social being), the ego (the conscious aspects of man), and the id, or libido (a "seething, boiling cauldron of desire that seeks to erupt from beneath the threshold of consciousness"). Thus, demons—according to this reinterpretation—might well be redefined as projections of the unregulated drives of man that force him to act only according to his own selfish desires, taking no account of their effects on other persons. From a social point of view, demons might also be defined as the environmental and hereditary forces that cause man to act, think, and speak in ways that are contrary to the well-being of himself and his community. A modern French writer, Denis de Rougemont, has maintained in his book *The Devil's Share* that the devil and the demonic forces that plague the modern world can be

well documented in modern man's return to barbarism and man's inhumanity to man. In the 2nd century AD, Clement of Alexandria, a Christian philosophical theologian, pointed toward a psychological interpretation of demonic forces by stating that man was often captivated by the inner appetitive drives of his passions and bodily desires. The Freudian "myth" of the human personality and other psychological studies have thus initiated a new dimension in the study of angels and demons. Medieval iconography, which graphically depicted angels and demons as hybrid creatures that often defied even the most vivid imaginations of the persons who viewed them, has been supplanted by psychological, psychoanalytical, and modern mythological symbolism coupled with theological reflection.

Relationship to views of a dualistic cosmos. In religious traditions that have viewed the cosmos in a dualistic fashion, such as Gnosticism, angels were believed to be celestial beings who controlled certain spheres through which a soul was to pass as it freed itself from the shackles of its material existence. Knowledge of these angels and their names was a necessary prerequisite for achieving eventual union with the ultimate spiritual reality. Included among various lists of the seven angels ruling the seven planetary spheres are Gabriel, Adonai (Lord), Aariel (lion of God), and others. The angel of the creation of the world of matter, Yahweh (sometimes called the Demiurge, the Creator), was evil, in the Gnostic view, not only because he was the Creator but also because he tried to keep spiritual men from knowing their true origin, nature, and destiny.

Angels as aids or hindrances to man's goal of salvation

Manichaeism, a dualistic religion founded in the 3rd century AD by Mani, an Iranian prophet, like Gnosticism divided the world into two spheres—Goodness (Light) and Evil (Darkness). These two principles are mixed in the world of matter, and the object of salvation is to unmix the material and the spiritual so that one may achieve a state of absolute goodness. Highest in the celestial hierarchy are the 12 light diadems of the Father of Greatness and the Twelve Aeons, the "firstborn"—angelic figures that are divided into groups of threes, surrounding the Supreme Being in the four quarters of the heavens. Because the Devil, the Prince of Darkness, desires the advantages of the Kingdom of Light, in an ensuing battle between the celestial forces Light and Darkness are mixed, and the world of matter and spirit is created. Unaware of his spiritual nature and constantly tempted by the demons of the Prince of Darkness, man is eventually led to understand his true nature through the activity of angelic beings called the Friends of the Lights and the Living Spirit and his five helpers: Holder of Splendour, King of Honour, Light of Man, King of Glory, and Supporter.

Relationship to views of a monistic cosmos. Those who view the cosmos as basically monistic—such as Hinduism, Jainism, and Buddhism—generally have no belief in angels, who function mainly as revealers of the truth. This function is performed by other beings, such as *avatāras* (incarnations of the gods) in Hinduism, *tīrthaṅkaras* (saints or prophets) in Jainism, or *bodhisattvas* (Buddhas-to-be) in Buddhism. Because such personages generally are viewed more in terms of exemplifiers of the holy life than as conduits of a revelation (except in the case of several *avatāras* and *bodhisattvas*), they are not to be regarded in terms of the typical Western conceptions of angelic beings. These religions do, however, have widespread beliefs in demons.

Belief in demons as common to all religious or mythological views about the cosmos. Belief in demons is not connected with any particular view of the cosmos. Demons have a very wide geographical and lengthy historical role as spiritual beings influencing man in his relationship to the sacred or holy. They may be semihuman, nonhuman, or ghostly human beings who, for various reasons, generally attempt to coerce man into not attaining his higher spiritual aspirations or not performing activities necessary for his well-being in the normal course of living. The ancient Assyrian demon *rabiṣu* apparently is a classic prototype of a supernatural being that instilled such a fear in men that their hair literally raised from their bodies when confronted with knowledge of the *rabiṣu*'s presence.

Powers of demons in the West

In 17th-century Europe, various demons were cataloged according to their powers to entice men to indulge in what were called their basic instincts or desires. Included in such lists were nightmare demons, demons formed from the semen of copulation, and demons who deceived persons into believing that they could perform transvections (nocturnal flights to sites of sabbats, alleged rites of witchcraft). According to some authorities in the 20th century (as well as early Christian polemicists), the alleged demons noted by the prevailing religions of the world are the former gods or spiritual beings that succumbed to or were overpowered by the dominant doctrinal views of a conquering people. Thus, the Teutonic, Slavic, Celtic, or Roman gods either were reduced to demonic antagonists of Christ, his saints, or his angels or were absorbed by the cults of Christian saint figures. Followers of the ancient but no longer influential deities were often subjected to persecution as advocates of witchcraft, especially in Christian Europe (see also OCCULTISM: *Witchcraft*).

TYPES OF ANGELS AND DEMONS

Angels and demons, as noted earlier, have been categorized as benevolent, malevolent, or ambivalent or neutral beings that mediate between the sacred and profane realms.

Benevolent beings. Benevolent beings, usually angels but sometimes ghosts of ancestors or other spiritual beings that have been placated by sacrifices or other rituals, assist man in achieving a proper rapport with God, other spiritual beings, or man's life situations. Angels, for example, not only act as revealers of divine truths, but they also are believed to be efficacious in helping man to attain salvation or special graces or favours. Their primary function is to praise and serve God and do his will. This is true of angels in both Christianity and Zoroastrianism, as well as in Judaism and Islām. As functional extensions of the divine will, they sometimes intervene in human affairs by rewarding the faithful and punishing the unjust or by saving the weak, who are in need of help, and destroying the wicked, who unjustly persecute their fellow creatures. In the intertestamental book of Tobit (an apocryphal, or "hidden," book that is not accepted as canonical by Jews and Protestants), the archangel Raphael (God Heals), for example, helps the hero Tobias, the son of Tobit, on a journey and also reveals to him magic formulas to cure his father's blindness and to counteract the power of the demon Asmodeus.

Functions of angels

Angels also have been described as participants in the creation and the providential continuance of the cosmos. Clement of Alexandria, influenced by Hellenistic cosmology, stated that they functioned as the movers of the stars and controlled the four elements—earth, air, fire, and water. Many angels are believed to be guardians over individuals and nations. The view that there are guardian angels watching over children has been a significant belief in the popular piety of Roman Catholicism. Angels are also regarded as the conductors of the souls of the dead to the supraterrestrial world. In the procreation of men, angels are believed to perform various services. This is especially noticeable in the instances of angels announcing the births of divine figures or special religious personages, such as Jesus and John the Baptist in the New Testament.

Though the function of angels is of primary significance, theological reflection and popular piety have placed much emphasis on the nature of angels. In early Judaism angels were conceived as beings in human form: the angel who wrestled with the patriarch Jacob, as recorded in the book of Genesis, was in the form of a man. In Judaism of the Hellenistic period (3rd century BC to 3rd century AD), however, angels were viewed as noncorporeal spiritual beings who appeared to man in an apparitional fashion. Their spiritual nature had been emphasized earlier by Old Testament prophets, such as Ezekiel and Isaiah, in their visionary descriptions. The cherubim and seraphim, two superior orders of angels, are described as winged creatures that guard the throne of God. The use of wings attached to various beings symbolizes their invisible and spiritual nature, a practice that can be traced back to the ancient Egyptians, who represented the battling sun-god Horus of Edfu as a winged disk. In Christian iconography

the spiritual nature of angels has been almost universally represented—until the 20th century—by winged human figures. Their spirituality and, therefore, their noncorporeality led to various kinds of speculation among theologians and common people about the nature of the appearances of angels, which has been recorded in both Scripture and legends based on popular piety. Some theologians, such as Augustine in the 4th and 5th centuries, stated that angels, who have ethereal bodies, may be able to assume material bodies. This problem, however, has not been solved to the satisfaction of later theologians.

Malevolent beings. Malevolent beings—demons, fallen angels, ghosts, goblins, evil spirits in nature, hybrid creatures, the *daevas* of Zoroastrianism, the *nārakas* (creatures of hell) of Jainism, the *oni* (attendants of the gods of the underworld) in Japanese religions, and other such beings—hinder man in achieving a proper relation with God, the spiritual realm, or man's life situations. Some angels are believed to have fallen from a position of proximity to God—such as Lucifer (after his fall called Satan by early Church Fathers) in Judaism, Christianity, and Islām—because of pride or for attempts to usurp the position of the Supreme Being. In their fallen condition they then attempt to keep man from gaining a right relationship with God by provoking men to sin. Some medieval scholars of demonology ascribed to a hierarchy of seven archdemons the seven deadly sins: Lucifer (Pride); Mammon (Avarice); Asmodeus (Lechery); Satan (Anger); Beelzebub (Gluttony); Leviathan (Envy); and Belphegor (Sloth). Besides tempting men to sin, the fallen angels, or devils, were believed to cause various types of calamities, both natural and accidental. Like the demons and evil spirits of nature in primitive religions, the fallen angels were viewed as the agents of famine, disease, war, earthquakes, accidental deaths, and various mental or emotional disorders. Persons afflicted with mental diseases were considered to be "demon possessed."

The function of demons

Though the functions of demonic figures, like those of fallen angels, is of major significance, the nature of demons has been of concern to theologians and persons infused with popular piety. Like angels, demons are regarded as spiritual, noncorporeal beings, but they have been depicted in religious iconography as hybrid creatures with horrifying characteristics or as caricatures of idols of an opposing religion. In the early church, for example, there was a belief that pagan idols were inhabited by demons. The horrifying aspects of demons have been represented in the woodcuts of medieval and Reformation artists and in the masks of shamans, medicine men, and priests of primitive religions—either to frighten the believer into behaving according to accepted norms or to ward off ritualistically the power of the demonic forces loose in the terrestrial or profane realm.

Ambivalent or neutral beings. Ambivalent or neutral spiritual beings are usually not found in Western religions, which usually divide the inhabitants of the cosmos into those who are either allied with or in opposition to the Supreme Being. Islām, however, classifies spiritual beings into angels (*malā'ikah*), demons (*shāyaṭīn*), and *djinni*, or genies. This last category includes spiritual beings that might be either benevolent or malevolent. According to legend, the *djinni* were created out of fire 2,000 years before the creation of Adam, the first man. Capable of both visibility and invisibility, a *djinni* could assume various forms—either animal or human—and could be either a help or a hindrance to man. By cunning, a superior use of intellect, or magic, a man might be able to manipulate a *djinni* for his own benefit.

The role of the *djinni*

Various minor nature spirits—such as the spirits of water, fire, mountains, winds, and other spirits recognized in primitive religions—are generally neutral, but, in order to keep them that way or to make them beneficial to man, proper sacrifices and rituals must be performed.

VARIETIES OF ANGELS AND DEMONS IN THE RELIGIONS OF THE WORLD

Intermediate beings between the sacred and profane realms assume various forms in the religions of the world: celestial and atmospheric beings; devils, demons, and evil spirits; ghosts, ghouls, and goblins; and nature spirits and fairies.

In Zoroastrianism, Judaism, Christianity, and Islām. In the Western religions, which are monotheistic and view the cosmos as a tripartite universe, angels and demons are generally conceived as celestial or atmospheric spirits. In the popular piety of these religions, however, there is a widespread belief in ghosts, ghouls, goblins, demons, and evil spirits that influence man in his terrestrial condition and activities. The celestial beings may be either benevolent or malevolent, depending on their own relationship to the Supreme Being. On the other hand, the demons and evil spirits that generally influence man in his role as a terrestrial being (rather than in his destiny as a supraterrestrial being) are viewed in popular piety—and somewhat in theological reflection—as malevolent in intent.

Angels are generally grouped in orders of four, six, or seven in the first ranks, of which there may be several. The use of four, which symbolically implies perfection and is related to the four cardinal points, is found in Judaism, Christianity, and Islām. Early Zoroastrianism, much influenced by the astronomical and astrological sciences of ancient Iran, coordinated the concept of the seven known planetary spheres with its belief in the heptad (grouping of seven) of celestial beings—*i.e.*, the *amesha spentas* of Ahura Mazdā: Spenta Mainyu (the Holy Spirit), Vohu Mana (Good Mind), Asha (Truth), Ārmaiti (Right Mindedness), Khshathra (Kingdom), Haurvatāt (Wholeness), and Ameretāt (Immortality). In later Zoroastrianism, though not in the *Gāthās* (the early hymns, believed to have been written by Zoroaster, in the Avesta, the sacred scriptures), Ahura Mazdā and Spenta Mainyu were identified with each other, and the remaining bounteous immortals were grouped in an order of six. Over against the bounteous immortals, who helped to link the spiritual and the material worlds together, was the counterpart of the Holy Spirit, namely Angra Mainyu, the Evil Spirit, who later became the great adversary Ahriman (the prototype of the Jewish, Christian, and Islāmic Satan), and the daevas, who were most likely gods of early Indo-Iranian religion. Allied with Angra Mainyu against Ahura Mazdā were Akōman (Evil Mind), Indrā-vāyū (Death), Saurva (a daeva of death and disease), Nāñhaithya (a daeva related to the Vedic god Nāsatya), Tauru (difficult to identify), and Zairi (the personification of Haoma, the sacred drink related to the sacrifices of both *ahuras* and daevas). Among other demonic figures is Aēshma (violence, fury, or the aggressive impulse that consumes man)—who may well be the demon Asmodeus of the book of Tobit, Āz (Concupiscence or Lust), Mithrāndruj (He Who Lies to Mithra or False Speech), Jēh (the demon Whore, created later by Ahriman to defile the human race), and many others (see also ZOROASTRIANISM AND PARSIISM).

The orders of ranks of angels and demons in Zoroastrianism

Angelology and demonology in Judaism became more highly developed during and after the period of the Babylonian Exile (6th–5th centuries BC), when contacts were made with Zoroastrianism. In the Old Testament, Yahweh is called the Lord of hosts. These hosts (Sabaoth) are the heavenly army that fights against the forces of evil and performs various missions, such as guarding the entrance to Paradise, punishing evildoers, protecting the faithful, and revealing God's Word to man. Two archangels are mentioned in the canonical Old Testament: Michael, the warrior leader of the heavenly hosts, and Gabriel, the heavenly messenger. Two are mentioned in the apocryphal Old Testament: Raphael, God's healer or helper (in the book of Tobit), and Uriel (Fire of God), the watcher over the world and the lowest part of hell (in II Esdras). Though these are the only four named, seven archangels are noted in Tob. 12:15. Besides the archangels, there were also other orders of angels, the cherubim and seraphim, which have been noted earlier.

The angels and demons of Judaism and Christianity

Under the influence of Zoroastrianism, Satan, the adversary, probably evolved into the archdemon. Other demons included Azazel (the demon of the wilderness, incarnated in the scapegoat), Leviathan and Rahab (demons of chaos), Lilith (a female night demon), and others. To protect themselves from the powers of the demons and unclean spirits, Jews influenced by folk beliefs and customs (as with Christians later) often carried charms,

amulets, and talismans inscribed with efficacious formulas (see also JUDAISM).

Christianity, probably influenced by the angelology of Jewish sects such as the Pharisees and the Essenes as well as of the Hellenistic world, further enhanced and developed theories and beliefs in angels and demons. In the New Testament, celestial beings were grouped into seven ranks: angels, archangels, principalities, powers, virtues, dominions, and thrones. In addition to these were added the Old Testament cherubim and seraphim, which, with the seven other ranks, comprised the nine choirs of angels in later Christian mystical theology. Various other numbers of the orders of angels have been given by early Christian writers: four, in *The Sibylline Oracles* (a supposedly Jewish work that shows much Christian influence); six, in the *Shepherd of Hermas,* a book accepted as canonical in some local early Christian churches; and seven, in the works of Clement of Alexandria and other major theologians. In both folk piety and theology the number has generally been fixed at seven. The angels receiving most attention and veneration in Christianity were the four angels mentioned in the Old Testament and the Apocrypha. Michael became the favourite of many, and in the practice of his cult there was often some confusion with St. George, who was also a warrior figure.

Demonology experienced a renewal in Christianity that probably would have been acceptable in Zoroastrianism. Satan, the archenemy of the Christ; Lucifer, the fallen Light Bearer; and the originally Canaanite Beelzebub, the Lord of Flies (or, perhaps, Beelzebul, the Lord of Dung), mentioned by Jesus, are all devils. The concept and term devil are derived from the Zoroastrian concept of *daevas* and the Greek word *daibolos* ("slanderer" or "accuser"), which is a translation of the Jewish concept of Satan. As a singular demonic force or personification of evil, the devil's chief activity was to tempt man to act in such a way that he would not achieve his supraterrestrial destiny. Because demons were believed to inhabit waterless wastelands, where hungry and tired persons often had visual and auditory hallucinations, early Christian monks went into the deserts to be the vanguard of God's army in joining battle with the tempting devils. They often recorded that the devil came to them in visions as a seductive woman, tempting them to violate their vows to keep themselves sexually pure, both physically and mentally.

Worship of demons in the West

During certain periods in Christian Europe, especially the Middle Ages, worship of demons and the practice of witchcraft brought about the wrath of both church and people on those suspected of practicing diabolical rites, such as the Black Mass. One formula from the Black Mass (the mass said in reverse and with an inverted crucifix on the altar) has survived in popular magic: "hocus-pocus," an abbreviated from of "Hoc est corpus meum" ("This is my body"), the words of institution in the Eucharist, or Holy Communion. Witchcraft and sorcery have been closely associated with demonology in the thought of Christianity, especially in the West.

In the second half of the 20th century, in connection with a renewed interest in the supernatural, there has been evidence of a revival of demon worship and black magic, although this has generally been restricted to small cults that have proved to be quite ephemeral.

Angelology and demonology in Islām are closely related to similar doctrines in Judaism and Christianity. Besides the four throne bearers of Allāh, four other angels are well known: Jibrīl (Gabriel), the angel of revelation; Mīkāl (Michael), the angel of nature, providing man with food and knowledge; 'Izrā'īl, the angel of death; and Isrāfīl, the angel who places the soul in the body and sounds the trumpet for the Last Judgment. Demons also contend for control of men's lives, the most prominent being Iblīs (the Devil), who tempts mortal man, or Shayṭan, or Satan (see also ISLĀM).

In the religions of the East. As noted earlier, the function of angels in Eastern religions was carried by *avatāras, bodhisattvas,* and other such spiritual beings who were extensions of God or the sacred. Belief in demons was and is very widespread, influencing various rituals and practices to counteract the forces that are hostile to man and nature. In Hinduism, the *asuras* (the Zoroastrian *ahuras*) are the demons who oppose the *devas* (the gods). Both vied for the *homa,* or the *amṛta* (the sacred drink that gives power), but the god Viṣṇu (the preserver), incarnated as a beautiful woman (Mohinī), aided the gods so that they alone would drink the *amṛta,* thus giving them power over the demons. Among the various classes of Hindu *asuras* (demons) are *nāgas* (serpent demons); Ahi (the demon of drought); and Kaṃsa (an archdemon). Demons that afflict men include the *rākṣasas,* grotesque and hideous beings of various shapes who haunt cemeteries, impel men to perform foolish acts, and attack *sadhus* (saintly men), and *piśacas,* beings who haunt places where violent deaths have occurred. Buddhists often view their demons as forces that inhibit man from achieving Nirvāṇa (bliss or the extinction of desire). Included among such beings are Māra, an arch tempter, who, with his daughters, Rati (Desire), Rāga (Pleasure), and Tanhā (Restlessness), attempted to dissuade Siddhārtha Gautama, the Buddha, from achieving his Enlightenment. As Mahāyāna (Greater Vehicle) Buddhism spread to Tibet, China, and Japan, many of the demons of the folk religions of these areas were incorporated into Buddhist beliefs. The demons of Chinese religions, the *kuei-shen,* are manifested in all aspects of nature. Besides these nature demons there are goblins, fairies, and ghosts. Because the demons were believed to avoid light, the Chinese who were influenced by Taoism and folk religions used bonfires, firecrackers, and torches to ward off the *kuei.* Japanese religions are similar to Chinese religions in the multiplicity of demons with which men must contend. Among the most fearsome of the Japanese demons are the *oni,* evil spirits with much power, and the *tengu,* spirits that possess man and that generally must be exorcized by priests (see also HINDUISM; BUDDHISM; JAINISM).

Types of demons in Eastern religions

In nonliterate religions. The spiritual beings of nonliterate religions of Asia, Africa, Oceania, and the Americas are generally viewed as malevolent or benevolent according to circumstances rather than because of their inherent nature. Eshu, a god of the Yoruba of Nigeria, for example, is looked upon as a protective, benevolent spirit as well as a spirit with an evil power that may be directed toward one's enemies. These beings possess what is called mana (supernatural power), a Melanesian term that can be applied both to spirits and to persons of special status, such as chiefs or shamans. In nonliterate religions, the spirits of nature are generally venerated in return for certain favours or to ward off catastrophes, much in the manner of the religion of ancient Rome. Ancestor gods abound, and thus the ghosts of the dead must be placated, often with the performance of elaborate rites (see also SACRED OFFICES AND ORDERS: *Shamanism*; RELIGIOUS AND SPIRITUAL BELIEF: *Ancestor worship*).

Conclusion. Though traditional beliefs in angels and demons have been questioned among those cultures affected by Western science and technology, reinterpretations of such beliefs, under the influence of psychological studies and the study of myth in the history of religions, have been of significance to theological reflection. By viewing angels and demons functionally, rather than in terms of their natures, modern man may discover that he has a greater kinship than he has generally realized with men of previous or different cultures in his attempt to gain an advantageous rapport with the transcendent, social, and psychological realms that he faces in everyday life. (L.F.)

Salvation

Salvation is the deliverance or redemption of man from such fundamentally negative or disabling conditions as suffering, evil, finitude, and death. In some religious beliefs it also entails the restoration or raising up of the natural world to a higher realm or state. The idea of salvation is a characteristic religious notion related to an issue of profound human concern.

NATURE AND SIGNIFICANCE

It could be argued reasonably that the primary purpose of all religions is to provide salvation for their adherents,

and the existence of many different religions indicates that there is a great variety of opinion about what constitutes salvation and the means of achieving it. That the term salvation can be meaningfully used in connection with so many religions, however, shows that it distinguishes a notion common to men and women of a wide range of cultural traditions.

The fundamental idea contained in the English word salvation, and the Latin *salvatio* and Greek *sōtēria* from which it derives, is that of saving or delivering from some dire situation. The term soteriology denotes beliefs and doctrines concerning salvation in any specific religion, as well as the study of the subject. The idea of saving or delivering from some dire situation logically implies that mankind, as a whole or in part, is in such a situation. This premise, in turn, involves a series of related assumptions about human nature and destiny.

Original and ultimate states of man and the world

Objects and goals. The creation myths of many religions express the beliefs that have been held concerning the original state of mankind in the divine ordering of the universe. Many of these myths envisage a kind of Golden Age at the beginning of the world, when the first human beings lived, serene and happy, untouched by disease, aging, or death and in harmony with a divine Creator. Myths of this kind usually involve the shattering of the ideal state by some mischance, with wickedness, disease, and death entering into the world as the result. The Adam and Eve myth is particularly notable for tracing the origin of death, the pain of childbirth, and the hard toil of agriculture, to man's disobedience of his maker. It expresses the belief that sin is the cause of evil in the world, and implies that salvation must come through man's repentance and God's forgiveness and restoration.

In ancient Iran, a different cosmic situation was contemplated, one in which the world was seen as a battleground of two opposing forces: good and evil, light and darkness, life and death. In this cosmic struggle, mankind was inevitably involved, and the quality of human life was conditioned by this involvement. Zoroaster, the founder of Zoroastrianism, called upon men to align themselves with the good, personified in the god Ahura Mazdā, because their ultimate salvation lay in the triumph of the cosmic principle of good over evil, personified in Ahriman. This salvation involved the restoration of all that had been corrupted or injured by Ahriman at the time of his final defeat and destruction. Thus the Zoroastrian concept of salvation was really a return to a Golden Age of the primordial perfection of all things, including man. Some ancient Christian theologians (*e.g.,* Origen) also conceived of a final "restoration" in which even devils, as well as men, would be saved; this idea, called universalism, was condemned by the church as heresy.

In those religions that regard man as essentially a psychophysical organism (*e.g.,* Judaism, Christianity, Zoroastrianism, Islām), salvation involves the restoration of both the body and soul. Such religions therefore teach doctrines

Resurrection and immortality

of a resurrection of the dead body and its reunion with the soul, preparatory to ultimate salvation or damnation. In contrast, some religions have taught that the body is a corrupting substance in which the soul is imprisoned (*e.g.,* Orphism, an ancient Greek mystical cult; Hinduism; and Manichaeism, an ancient dualistic religion of Iranian origin). In this dualistic view of human nature, salvation has meant essentially the emancipation of the soul from its physical prison or tomb and its return to its ethereal home. Such religions generally explain the incarceration of the soul in the body in terms that imply the intrinsic evil of physical matter. Where such views of human nature were held, salvation therefore meant the eternal beatitude of the disembodied soul.

Christian soteriology contains a very complex eschatological program (regarding the final end of man and the world), which includes the fate of both individual persons and the existing cosmic order. The return of Christ will be heralded by the destruction of the heaven and earth and the resurrection of the dead. The Last Judgment, which will then take place, will result in the eternal beatitude of the just, whose souls have been purified in purgatory, and the everlasting damnation of the wicked. The saved, reconstituted by the reunion of soul and body, will forever enjoy the Beatific Vision; the damned, similarly reconstituted, will suffer forever in hell, together with the devil and the fallen angels. Some schemes of eschatological imagery, used by both Christians and Jews, envisage the creation of a new heaven and earth, with a New Jerusalem at its centre.

Means. The hope of salvation has naturally involved ideas about how it might be achieved. These ideas have varied according to the form of salvation envisaged; but the means employed can be divided into three significant categories: (1) the most primitive is based on belief in the efficacy of ritual magic—initiation ceremonies, such as those of the ancient mystery religions, afford notable examples; (2) salvation by self-effort, usually through the acquisition of esoteric knowledge, ascetic discipline, or heroic death, has been variously promised in certain religions—Orphism, Hinduism, Islām, for example; and (3) salvation by divine aid, which has usually entailed the concept of a divine saviour who achieves what man cannot do for himself—as in Christianity, Judaism, Islām.

BASIC CONTEXT

Man's awareness of time and death

The cosmic situation. *Time.* Study of the relevant evidence shows the menace of death as the basic cause of soteriological concern and action. Salvation from disease or misfortune, which also figures in religion, is of a comparatively lesser significance, though it is often expressive of more immediate concerns. But the menace of death is of another order, and it affects man more profoundly because of personal awareness of the temporal categories of past, present, and future. This time-consciousness is possessed by no other species with such insistent clarity. It enables man to draw upon past experience in the present and to plan for future contingencies. This faculty, however, has another effect: it causes man to be aware that he is subject to a process that brings change, aging, decay, and ultimately death to all living things. Man, thus, knows what no other animal apparently knows about itself, namely, that he is mortal. He can project himself mentally into the future and anticipate his own decease. Man's burial customs grimly attest to his preoccupation with death from the very dawn of human culture in the Paleolithic Period. Significantly, the burial of the dead is practiced by no other species.

The menace of death is thus inextricably bound up with man's consciousness of time. In seeking salvation from death, man has been led on to a deeper analysis of his situation, in which he has seen in his subjection to time the true cause of the evil that besets him. The quest for salvation from death, accordingly, becomes transformed into one for deliverance from subjugation to the destructive flux of time. How such deliverance might be effected has been conceived in varying ways, corresponding to the terms in which the temporal process is imagined. The earliest known examples occur in ancient Egyptian religious texts. In the so-called Pyramid Texts (*c.* 2400 BC), the dead pharaoh seeks to fly up to heaven and join the sun-god Re on his unceasing journey across the sky, incorporated, thus, in a mode of existence beyond change and decay. A passage in the later Book of the Dead (1200 BC) represents the deceased, who has been ritually identified with Osiris, declaring that he comprehends the whole range of time in himself, thus asserting his superiority to it.

The recognition that mankind is subject to the inexorable law of decay and death has produced other later attempts to explain its domination by time and to offer release from it. Such attempts are generally based on the idea that the temporal process is cyclical, not linear, in its movement.

Man's deliverance from time and death

Into this concept, a belief in metempsychosis (transmigration of souls) can be conveniently fitted. For the idea that souls pass through a series of incarnations becomes more intelligible if the process is seen as being cyclical and in accordance with the pattern of time that apparently governs all the forms of being in this world. The conception has been elaborated in various ways in both Eastern and Western religions. In Hinduism and Buddhism, elegantly imaginative chronological systems have been worked out, comprising *mahāyugas,* or periods of 12,000 years, each

year of which represented 360 human years. In turn, 1,000 *mahāyugas* made up one *kalpa*, or one day in the life of Brahmā, and spanned the duration of a world from its creation to its destruction. After a period of quiescence, the world would be re-created by Brahmā for another *kalpa*. The purpose of this immense chronological scheme was to emphasize how the unenlightened soul was doomed to suffer an infinite series of incarnations, with all of their attendant pain of successive births and deaths. In the Orphic texts of ancient Greece, man's destiny to endure successive incarnations is significantly described as "the sorrowful weary Wheel," from which the Orphic initiate hoped to escape through the secret knowledge imparted to him.

Nature. As an alternative interpretation to this view of man's fatal involvement with time, the tragedy of the human situation has also been explained in terms of the soul's involvement with the physical universe. In some systems of thought (*e.g.*, Hinduism and Buddhism), the two interpretations are synthesized; and in such systems it is taught that, by accepting the physical world as reality, the soul becomes subject to the process of time.

Man's deliverance from the body and the natural world

Concentration on the soul's involvement with matter as being the cause of the misery of human life has generally stemmed from a dualistic view of human nature. The drawing of a sharp distinction between spirit and matter has been invariably motivated by a value judgment: namely, that spirit (or soul) is intrinsically good and of transcendent origin, whereas matter is essentially evil and corrupting. Through his body, man is seen to be part of the world of nature, sharing in its processes of generation, growth, decay, and death. How his soul came to be incarcerated in his corruptible body has been a problem that many myths seek to explain. Such explanations usually involve some idea of the descent of the soul or its divine progenitor from the highest heaven and their fatal infatuation with the physical world. The phenomenon of sexual intercourse has often supplied the imagery used to account for the involvement of the soul in matter and the origin of its corruption. Salvation has thus been conceived in this context as emancipation from both the body and the natural world. In Gnosticism and Hermeticism—esoteric theosophical and mystical movements in the Greco-Roman world—and the teaching of St. Paul deliverance was sought primarily from the planetary powers that were believed to control human destiny in the sublunar world.

Man's responsibility. The idea that man is in some dire situation, from which he seeks to be saved, necessarily involves explaining the cause of his predicament. The explanations provided in the various religions divide into two kinds: those that attribute the cause to some primordial mischance and those that hold man to be himself responsible. Some explanations that make man directly responsible represent him also as the victim of the deceit of a malevolent deity or demon.

Because death has been universally feared but rarely accepted as a natural necessity, the mythologies of many peoples represent the primeval ancestors of mankind as having accidentally lost, in some way, their original immortality. One Sumerian myth, however, accounts for disease and old age as resulting from the sport of the gods when they created mankind. In contrast, the Hebrew story of Adam and Eve finds the origin of death in their act of disobedience in eating of the tree of knowledge of good and evil, forbidden to them by their maker. This causal connection between sin and death was elaborated by St. Paul in his soteriology, outlined in his letter to the Romans, and formed the basis of the Christian doctrine of original sin. According to this doctrine, through seminal identity with Adam, every human being must partake of the guilt of Adam's sin, and even at birth, a child is already deserving of God's wrath for its share in the original sin of mankind and before it acquires the guilt of its own actual sin. Moreover, because each individual inherits the nature of fallen humanity, he has an innate predisposition to sin. This doctrine of man means that no person can, by his volition and effort, save himself but depends absolutely upon the saving grace of Christ.

Moral and intellectual defects

Wherever a dualistic view of human nature has been held, it has been necessary to explain how ethereal souls first became imprisoned in physical bodies. Generally, the cause has been found in the supposition of some primordial ignorance or error rather than in a sinful act of disobedience or revolt—*i.e.*, in an intellectual rather than a moral defect. According to the Hindu philosophical system known as Advaita Vedānta, a primordial ignorance (*avidyā*) originally caused souls to mistake the empirical world for reality and so become incarnated in it. By continuing in this illusion, they are subjected to an unceasing process of death and rebirth (*saṃsāra*) and all of its consequent suffering and degradation. Similarly, in Buddhism, a primordial ignorance (*avijjā*) also started the "chain of causation" (*paṭiccasamuppāda*) that produces the infinite misery of unending rebirth in the empirical world.

METHODS AND TECHNIQUES

Ritual. The means by which salvation might be achieved has been closely related to the manner in which salvation has been conceived and to what has been deemed to be the cause of man's need of it. Thus in ancient Egypt, where salvation was from the physical consequences of death, a technique of ritual embalmment was employed. Ritual magic has also been used in those religions that require their devotees to be initiated by ceremonies of rebirth (*e.g.*, Baptism in water in Christianity, in bull's blood in rites of Cybele) and by symbolic communion with a deity through a ritual meal in the Eleusinian Mysteries, Mithraism, and Christianity (communion).

Knowledge. Religions that trace the ills of man's present condition to some form of primordial error, or ignorance, offer knowledge that will ensure salvation. Such knowledge is of an esoteric kind and is usually presented as divine revelation and imparted secretly to specially prepared candidates. In some instances (*e.g.*, Buddhism and Yoga), the knowledge imparted includes instruction in mystical techniques designed to achieve spiritual deliverance.

Devotion and service. Whenever mankind has been deemed to need divine aid for salvation, there has been an emphasis on a personal relationship with the saviour-god concerned. Such relationship usually connotes faith in and loving devotion and service toward the deity, and such service may involve moral and social obligations. Judaism, Christianity, Islām, and the *bhakti* cults of India afford notable examples. Christianity adds a further requirement in this context: because human nature is basically corrupted by sin, God's prevenient (antecedent, activating) grace is needed before man's will can be disposed even to desire salvation.

VARIETIES OF SALVATION IN WORLD RELIGIONS

Ancient Egypt. The Pyramid Texts of ancient Egypt provide the earliest evidence of man's quest for salvation. They reveal that by about 2400 BC a complex soteriology connected with the divine kingship of the pharaohs had been established in Egypt. This soteriology was gradually developed in concept and ritual practice and was popularized; *i.e.*, the original royal privilege was gradually extended to all of the classes of society, until by about 1400 BC it had become an elaborate mortuary cult through which all who could afford its cost could hope to partake of the salvation it offered. This salvation concerned three aspects of postmortem existence, as imagined by the ancient Egyptians, and, in the concept of Osiris, it involved the earliest instance of a saviour-god. An elaborate ritual of embalmment was designed to save the corpse from decomposition and restore its faculties so that it could live in a well-equipped tomb. This ritual imitated the acts that were believed to have been performed by the gods to preserve the body of Osiris, with whom the deceased was ritually assimilated. The next concern was to resurrect the embalmed body of the dead person, as Osiris had been resurrected to a new life after death. Having thus been saved from the consequences of death, the revivified dead had to undergo a judgment (presided over by Osiris) on the moral quality of his life on earth. In this ordeal, the deceased could be saved from an awful second death only by personal integrity. If he safely passed the test, he was declared *maa kheru* ("true of voice") and was admitted to the beatitude of the realm over which Osiris reigned.

Postmortem salvation through Osiris

This Osirian mortuary cult, with its promise of post-mortem salvation, was practiced from about 2400 BC until its suppression in the Christian Era. In some respects, it constitutes a prototype of Christianity as a salvation religion.

Hinduism. Running through the great complex of beliefs and ritual practices that constitute Hinduism is the conviction that the soul or self (*ātman*) is subject to *saṃsāra—i.e.,* the transmigration through many forms of incarnation. Held together with this belief is another, *karman—i.e.,* that the soul carries with it the burden of its past actions—which conditions the forms of its future incarnations. As long as the soul mistakes this phenomenal world for reality and clings to existence in it, it is doomed to suffer endless births and deaths. The various Indian cults and philosophical systems offer ways in which to attain *mokṣa* or *mukti* ("release"; "liberation") from the misery of subjection to the inexorable process of cosmic time. Basically, this liberation consists in the soul's effective apprehension of its essential unity with Brahman, the supreme *Ātman* or essence of reality, and its merging with it. Most of the ways by which this goal may be attained require self-effort in mastering meditation techniques and living an ascetic life. But, in the devotional (*bhakti*) cults associated with Viṣṇu (Vishnu) and Śiva (Shiva), an intense personal devotion to the deity concerned is believed to earn divine aid to salvation.

Buddhism. Buddhism accepts the principles of *saṃsāra* and *karman* (Pāli: *kamma*), but it differs in one important respect from the Hindu conception of man. Instead of believing that an *ātman,* or soul, passes through endless series of incarnations, Buddhism teaches that there is no such preexistent immortal soul that migrates from body to body. Each individual consists of a number of physical and psychic elements (*khandhas*) that combine to create the sense of personal individuality. But this combination is only temporary and is irreparably shattered by death, leaving no element that can be identified as the soul or self. By a subtle metaphysical argument, however, it is maintained that the craving for personal existence generated by the *khandhas* causes the birth of another such personalized combination, which inherits the *karma* of a sequence of previous combinations of *khandhas.*

Salvation through Enlightenment or *bodhisattvas*

The Enlightenment won by Gautama Buddha was essentially about the cause of existence in the phenomenal world, from which suffering inevitably stemmed. Buddhist teaching and practice have, accordingly, been designed to acquaint men with their true nature and situation and enable them to free themselves from craving for existence in the space-time world and so achieve Nirvāṇa. Traditionally, this goal has been presented in negative terms—as the extinction of desire, attachment, ignorance, or suffering—creating the impression that Buddhist salvation means the complete obliteration of individual consciousness. In one sense, this is so; but, in terms of Buddhist metaphysics, ultimate reality transcends all the terms of reference relevant to existence in this world.

Theoretically, the Buddhist initiate should, by his own effort in seeking to eradicate desire for continued existence in the empirical world, achieve his own salvation. But, as Buddhism developed into a popular religion in its Mahāyāna ("Greater Vehicle") form, provision was made for the natural human desire for assurance of divine aid. Consequently, belief in many saviours, known as *bodhisattvas* ("Buddhas-to-be"), developed, together with elaborate eschatologies concerning human destiny. According to these, before the ultimate achievement of Nirvāṇa, the faithful could expect to pass through series of heavens or hells, according to their merits or demerits and the intensity of their devotion to a *bodhisattva.*

Judaism. Because Judaism is by origin and nature an ethnic religion, salvation has been primarily conceived in terms of the destiny of Israel as the elect people of Yahweh, the God of Israel. It was not until the 2nd century BC that there arose a belief in an afterlife, for which the dead would be resurrected and undergo divine judgment. Before that time, the individual had to be content that his posterity continued within the holy nation. But, even after the emergence of belief in the resurrection of the dead, the essentially ethnic character of Judaism still decisively influenced soteriological thinking. The apocalyptic faith, which became so fervent as Israel moved toward its fateful overthrow by the Romans in AD 70, conceived of salvation as the miraculous intervention of Yahweh or his Messiah in world affairs. This saving act would culminate in the Last Judgment delivered on the nations that oppressed Israel and Israel's glorious vindication as the people of God. From the end of the national state in the Holy Land in AD 70, Jewish religion, despite the increasing recognition of personal significance, has remained characterized by its essential ethnic concern. Thus, the Exodus from Egypt has ever provided the typal imagery in terms of which divine salvation has been conceived, its memory being impressively perpetuated each year by the ritual of the Passover. The restoration of the holy nation, moreover, always has been linked with its Holy Land; and Hebrew literature, both in biblical and later forms, has lovingly described the establishment of a New Jerusalem and a new Temple of Yahweh ("the Lord"), whether it be in this world or in some new cosmic order. Into this new order, the rest of mankind, repentant and purified, will be incorporated; for the original promise made to the patriarch Abraham included all men within the divine blessing. In the Book of Zechariah, the ultimate salvation of mankind is graphically envisaged: the Gentiles, in company with the Jews, will return to serve God in an ideal Jerusalem.

Salvation through Yahweh's action and power

Christianity. Christianity has been described as the salvation religion par excellence. Its primary premise is that the incarnation and sacrificial death of its founder, Jesus Christ, formed the climax of a divine plan for mankind's salvation. This plan was conceived by God consequent on the Fall of Adam, the progenitor of the human race, and it would be completed at the Last Judgment, when the Second Coming of Christ would mark the catastrophic end of the world. This soteriological evaluation of history finds expression in the Christian division of time into two periods: before Christ (BC) and Anno Domini (AD)—*i.e.,* the years of the Lord.

Salvation through Christ

The evolution of the Christian doctrine of salvation was a complicated process essentially linked with the gradual definition of belief in the divinity of Jesus of Nazareth. In Christian theology, therefore, soteriology is an integral part of what is termed Christology. Whereas the divinity of Jesus Christ has been the subject of careful metaphysical definition in the creeds, the exact nature and mode of salvation through Christ has not been so precisely defined. The church has been content to state, in its creeds, that Christ was incarnated, crucified, died, and rose again "for us men, and for our salvation."

The basic tenets of Christian soteriology may be summarized as follows: man is deserving of damnation by God for the original sin, which he inherits by descent from Adam, and for his own actual sin. But, because sin is regarded as also putting man in the power of the devil, Christ's work of salvation has been interpreted along two different lines. Thus, his crucifixion may be evaluated as a vicarious sacrifice offered to God as propitiation or atonement for human sin. Alternatively, it may be seen as the price paid to redeem man from the devil. These two ways of interpreting the death of Christ have provided the major themes of soteriological theory and speculation in Christian theology. Despite this fluidity of interpretation, belief in the saving power of Christ is fundamental to Christianity and finds expression in every aspect of its faith and practice.

Islām. Muḥammad regarded himself as "a warner clear" and as the last and greatest of a line of prophets whom Allāh had sent to warn his people of impending doom. Although the word *najāt* (Arabic: "salvation") is used only once in the Qur'ān, the basic aim of Islām is salvation in the sense of escaping future punishment, which will be pronounced on sinners at the Last Judgment. Muḥammad did teach that Allāh had predestined some men to heaven and others to hell; but the whole logic of his message is that submission to Allāh is the means to salvation, for Allāh is merciful. Indeed, faithful submission is the quintessence of Islām, the word Islām itself meaning submission. Although in his own estimation Muḥammad was the

prophet of Allāh, in later Muslim devotion he came to be venerated as the mediator between God and man, whose intercession was decisive.

Zoroastrianism and Parsiism. According to Zoroaster, a good and evil force struggled for mastery in the universe. Man had to decide on which side to align himself in this fateful contest. This dualism was greatly elaborated in later Zoroastrianism and Parsiism, which derived from it. Good, personified as the god Ormazd, and evil, as the demonic Ahriman, would contend for 12,000 years with varying fortune. At last Ormazd would triumph, and Saoshyans, his agent, would resurrect the dead for judgment. The righteous would pass to their reward in heaven, and the wicked be cast into hell. But this situation was of temporary duration. A meteor would later strike the earth, causing a flood of molten metal. Through this flood all would have to pass as an ordeal of purgation. The sensitivity of each to the anguish would be determined by the degree of his guilt. After the ordeal, all men would become immortal, and all that Ahriman had harmed or corrupted would be renewed. Salvation thus took the form of deliverance from postmortem suffering; for ultimate restoration was assured to all after suffering the degree of purgation that the nature of their earthly lives entailed. (S.G.F.B.)

Providence

Providence is the quality in divinity on which man bases his belief in a benevolent divine intervention in human affairs and the affairs of the world he inhabits. The forms that this belief takes differ, depending on the context of the religion and the culture in which they function.

In one view the concept of Providence, divine care of man and the universe, can be called the religious answer to man's need to know that he matters, that he is cared for, or even that he is threatened, for in this view all religions are centred on man, and man is individually and collectively in constant need of reassurance that he is not an unimportant item in an indifferent world; if he cannot be comforted, to be threatened is better than to be alone in an empty void of nothingness. According to J. van Baal, a Dutch anthropologist,

> Man experiences his universe as a universe full of intentions, a universe which holds a claim on him, addressing him with something undefined, urging him to act or to be in some way or another. The experience is strongest in moments of crisis, when events turn up with such an overwhelming force that it is as if they address their victim, delivering a message to him.

In answer to such a universe, religions must offer a coherent view of God or gods, world, and mankind and must give man and his physical or psychical well-being, or both, a prominent place within this world view. Thus, in all religions Divine Providence or its equivalent is an element of some importance.

NATURE AND SIGNIFICANCE

Basic forms of Providence. Basically, there are two possible forms of belief in Providence. In the first, man believes in more or less divine beings that are responsible for the world generally and for the welfare of man specifically. Although omnipotence as an attribute of gods is rare, it is true that, as a rule, gods and other divine beings have considerable power not only over man but also over nature. The gods take care of the world and of mankind, and their intentions toward mankind are normally positive. The capricious and arbitrary gods of paganism exist for the most part only in the imagination of those Christian theologians who attempt to denigrate the pagan religions. Gods and men are generally connected into one community by reciprocal duties and privileges. The belief in evil spirits does not contradict this belief in Providence but, on the contrary, strengthens it, just as in Christianity the belief in the devil might serve to strengthen the belief in God.

Belief in a cosmic order

In the second form, man believes in a cosmic order in which the welfare of man has its appointed place. This cosmic order is usually conceived as a divine order that is well intentioned toward man and is working for man's well-being as long as he is willing to insert himself into this order, to follow it willingly, and not to upset it by perversion or rebellion; the firmness of the order, however, may become inexorable and thus lead to fatalism, the belief in an impersonal destiny against which man is powerless. In that case a clash between the concepts of Providence and fatalism is inevitable. In most religions, however, both views are combined in some way.

Etymological history of the term Providence. The English word Providence is derived from the Latin term *providentia,* which primarily means foresight or foreknowledge but also forethought and Providence in the religious sense; thus, Cicero used the phrase the "Providence of the gods" (*deorum providentia*). The Stoic philosophers thoroughly discussed the significance of the term Providence, and some of them wrote treatises on the subject. A hymn to Zeus written about 300 BC by Cleanthes, a Greek poet and philosopher, is a glorification of the god as a benevolent and foreseeing ruler of the world and of mankind. According to Cleanthes, God has planned the world in accordance with this Providence:

> For thee this whole vast cosmos, wheeling round
> The earth, obeys, and where thou leadest
> It follows, ruled willingly by thee.

The author asserts that "naught upon Earth is wrought in thy despite, O God" and that in Zeus all things are harmonized. Seneca, a Roman Stoic philosopher, formulates the belief in Providence in one of his dialogues as follows: man should believe "that Providence rules the world and that God cares for us." The Stoic school disagreed with those who believed that the world was ruled by blind fate; they did not deny that a controlling power exists, but, as everything happens according to a benevolent divine plan, they preferred to call this power Providence. According to the Stoic emperor Marcus Aurelius, God wills everything that happens to man, and for that reason nothing that occurs can be considered evil. Stoic ideas about Providence influenced Christianity.

In later Latin after the emperor Augustus, the word Providence was used as a designation of the deity. Seneca, for example, wrote that it is proper to apply the term Providence to God. Finally, Providence was personified as a proper goddess in her own right by Macrobius, a Neoplatonic Roman author, who wrote in defense of paganism about 400.

Epicurus, a 4th–3rd-century-BC Greek philosopher, contested the Stoic belief in Divine Providence, but the objections of his followers could not change the spiritual climate of the Greco-Roman world. More eloquent, perhaps, than the dissertations of the learned Stoic philosophers were the many stories found in a work by Aelian, an early 3rd-century-AD Roman rhetorician, about strange events and miraculous occurrences ascribed to Providence. Aelian, however, was more interested in sensational stories than in historic accuracy.

Latin meanings of the word

The several meanings of the Latin word *providentia* exactly mirror those of its Greek equivalent, *pronoia.* Herodotus, the historian of the 5th century BC, was the first Greek author to use the word in a religious sense when he mentioned Divine Providence as the source of the wisdom that keeps nature in balance and prevents one kind of creature from prevailing over all others. Writers such as the historian Xenophon and the biographer Plutarch used the word for the watchful care of the gods over mankind and the world.

The belief in the existence of a blind and inexorable fate can lead to a conflict with the belief in a benevolent Providence. In the Greco-Roman world, where fatalistic belief was strong and where it found a popular expression in astrology, the belief that the whole world, but particularly man, is governed by the stars was contested by Judaism and Christianity. The Talmud, the authoritative collection of Jewish tradition, teaches that Israel is subject to no star but only to God. An example of this conflict is also found in the novel *The Golden Ass* by Apuleius, a 2nd-century-AD philosopher and rhetorician deeply interested in Hellenistic mystery cults, which taught a faith that liberated man from the power of the stars. In the novel the hero is converted to the goddess Isis; then, the priest of the goddess addresses him:

"Lucius, my friend," he said, "you have endured and performed many labours and withstood the buffetings of all the winds of ill luck. Now at last you have put into the harbour of peace and stand before the altar of loving-kindness. Neither your noble blood and rank nor your education sufficed to keep you from falling a slave to pleasure; youthful follies ran away with you. Your luckless curiosity earned you a sinister punishment. But blind Fortune, after tossing you maliciously about from peril to peril has somehow, without thinking what she was doing, landed you here in religious felicity. Let her begone now and fume furiously wherever she pleases, let her find some other plaything for her cruel hands. She has no power to hurt those who devote their lives to the honour and service of our Goddess's majesty."

Christian use of the term

The Christian use of the term Providence, besides being profoundly influenced by Greek and Roman thought, is based on the Old Testament story of the patriarch Abraham's sacrifice of his son Isaac, which is found in the book of Genesis. Abraham tells Isaac, "God will provide himself with a young beast for a sacrifice, my son." The Hebrew language lacks a proper word to express the notion of Providence, but the concept is well known in the Old Testament.

In the New Testament the word *pronoia* and related words are used rarely, but in no case are they used in the later Christian sense of Providence. This is of interest because the idea of Providence as such is far from foreign to the religious thinking of the New Testament. In the Gospel According to Matthew, for example, Jesus says:

Are not two sparrows sold for a penny? And not one of them will fall to the ground without your Father's will. But even the hairs of your head are numbered. Fear not, therefore; you are of more value than many sparrows.

Providence as used in Christianity is thus a dogmatic term rather than a biblical term; it indicates that God not only created the world but also governs it and cares for its welfare. A well-known German reference work, *Religion in Geschichte und Gegenwart* ("Religion in History and the Present"), gives a more elaborate and more theological definition of Providence:

God keeps the world in existence by his care, he rules and leads the world and mankind deliberately according to his purpose, and he does this in his omnipotence as God the Creator, in his goodness and love as revealed by his son Jesus Christ, and to further the salvation of mankind through the Holy Spirit.

BASIC CONCEPTS AND SCOPE

Qualities of the divinity. The concept of Providence is rooted in the belief in the existence of a benevolent, wise, and powerful deity or a number of beings that are benevolent and that are either fully divine or, at least, appreciably wiser and more powerful than man (*e.g.*, ancestors in many religions). Benevolence is the primary requirement. In northern Malawi, death in later life is usually ascribed to the will of the ancestors, but a miscarriage or the death of a very young child is not considered to be their work because such an act would be in contradiction with their benevolent and helpful attitude toward their offspring. The three attributes, however, are all essential for the concept of Providence: the divine being or beings must be well intentioned toward man, must have the necessary wisdom to know what is good for mankind, and must have the power to act on this intention and insight. Benevolence does not exclude the possibility of punishment in cases of transgression. There is probably no god in existence who only rewards and helps and never punishes his believers.

Providence, however, need not operate in a direct way; it may operate through many intermediary beings—*e.g.*, the ancestors and various kinds of spirits in several nonliterate religions or the angels in Christian and Muslim belief—or the concept may be implicit in and expressed by a fixed world order, a cosmic order that makes human life possible biologically, socially, and spiritually and that guarantees its existence in the future. Thus, Providence may become a more or less impersonal principle of cosmic order as instituted and maintained by a divine being, but, if the starting point of a benevolent and just divine being is completely lost sight of or if it is consciously denied, then Providence becomes fate.

Cosmic order. *Notion of cosmic order.* Although the introduction of intermediary beings brings no essential change in the idea of Providence as the divine watchful care for the benefit of mankind, the notion of a cosmic order changes the picture profoundly. Even if the cosmic order is conceived as a benevolent order in which man is able to feel safe and whose very existence reassures him, such an order is different from the personal relationship between man and his god or gods. The concept of an unchangeable world order requires a different reaction. A personal god may, perhaps, be moved by prayer and sacrifice to give or to prevent events; when the order of the world is fixed, however, the course of events cannot be changed by these or any other means. There is probably no religion that acknowledges an all-embracing world order without any exceptions at all. Generally, human beings have such an important function in the order of the world that they also have a certain opportunity to manipulate this order, at least to a certain extent, for instance, by sacrifice or other ritual acts. One opening is presented by the fact that the cosmic order is valid for everything of a more general character, but as a rule the divine will or the free will of man or chance operates on the level of the common occurrences and daily life of the individual. Though in theory the order may govern everything, a large field is left open for different concepts to function. In some cases even uncertainty and chance have their proper place within a determined order. In Yoruba religion (Nigeria), for example, the god Eshu represents the principle of chance and uncertainty and of all that cannot be foreseen. He is one of the gods of the pantheon and has his own sanctuaries and priests.

Manipulation of order and predestination

Another possibility for combining the idea of a personal divine will with a fixed course of events is the concept of predestination best known from Islām and some forms of Calvinism (derived from the thought of John Calvin, a 16th-century French Protestant Reformer) and also important in the theology of Augustine of Hippo, a 4th–5th-century Church Father. Although predestination essentially is concerned with salvation—the question of whether a certain individual will be saved or damned—it is a concept that easily lends itself to a more general application. In a few religions the idea that the individual chooses his own destiny before birth is encountered; *e.g.*, the Batak of Sumatra and some West African tribes. In this conception free will and predestination merge.

In all religions that acknowledge the existence of a more or less impersonal cosmic order, man is expected to work with the cosmos, to insert himself into the cosmic order. Man's behaviour in all fields is governed by a set of rules that are all based on the same principle: to act and to be in harmony with the order of the world, which is natural and divine at the same time.

The cosmic order is given with the creation of the world, but it is possible to question the relation of the Creator to the world after creation. On one hand, there is the belief that God will not abandon the world he has created; on the other, the belief that God created the world and the cosmic order in such a manner that to a great extent the course of the world is fixed from the first beginning and he is no longer involved in it. The latter was, in fact, the thesis of the 17th- and 18th-century Deists in Europe (see RELIGIOUS AND SPIRITUAL BELIEF: *Deism*). The fact of creation helps man to believe in Providence because it would be inconsistent for the creator god or gods not to care for the further existence of the created world. Only persistent disobedience and open rebellion can then furnish a reason for the Creator to abandon or destroy the world. This situation is expressed in the myths of a great flood or some other form of destruction sent as a punishment. There is, however, never a total destruction of the world in these myths, although this final solution may be threatened for the eschatological (ultimate end) future. It may also be promised, if the eschatological events are construed as the definitive institution of a world order that is perfect for all eternity and will never deteriorate.

Cosmic order and ethical principles

The cosmic order is often clearly contrasted with the disorder of chaos. The cosmic order is a total order: it comprises not only all natural things but also social and

ethical rules. This does not mean that cultures and religions centred on a cosmic order have no clear idea of distinctive ethical principles but that ethics is considered as one function of the total cosmic order and as such can never be quite independent. The rules of ethics depend on and are derived from the more general rules that govern the cosmos in its totality; they are no more than special manifestations of these general rules. An example of this attitude can be found in the Greek hymns in praise of the goddess Isis. She is honoured as the queen of heavens; she divided the earth from the heaven, showed the stars their paths, and ordered the course of the sun and the moon. But the same hymn says that she ordained that children should love their parents, that she taught men to honour the images of the gods, and that she made justice stronger than gold and silver. She established penalties for the people practicing injustice and taught that men should have mercy with suppliants. She is also praised because she invented writing, devised marriage contracts, invented navigation, and watches over all men who sail on the sea.

Personal and impersonal forms. The cosmic order can appear in a personalized form, as, for example, the Egyptian goddess Maat; but this personification of the cosmic order is not general: the Iranian Asha, the Indian *ṛta,* and the Chinese Tao are all to a high degree impersonal. Maat represents truth and order; her domain includes not only the order of the nature, but also the social and ethical orders. She plays an important role in the judgment of the dead: the heart of the deceased is weighed against the truth of Maat. She is often called the daughter of Re. In this case, Re is the creator god who not only created the world but also founded the cosmic order as represented by Maat. Her importance is also apparent in the conception of the Maat sacrifice. In Egypt sacrifice is not so much a gift of men to the gods as a sacral technique that enables man to contribute to the maintenance and, if necessary, the restoration of harmony and order in the world. Not only must man live according to Maat but also the gods must live by her truth and order; according to Egyptian texts, the goddess Maat is the food by which the gods live.

Asha, *ṛta,* and Tao

The idea of a determined cosmic order that is natural as well as ethical is an important concept in the Persian religion of Zoroastrianism (also called Mazdaism and, in India, Parsiism) founded during the late 7th and early 6th centuries BC by Zoroaster (Zarathustra). This idea is called Asha and is the counterpart of Drug, which represents evil and deceit and the disorder connected with these. Asha is connected with the sacred element fire. The Indian concept of *ṛta* forms the Indian counterpart of Asha. The gods, especially the Ādityas, protect the world against chaos and ignorance and maintain the world order, which, however, exists independently from the gods. Although the power of *ṛta* operates according to its own principles and laws, man is able, provided he knows the right methods, to manipulate this power to some extent for his own benefit. The proper means for this manipulation is found especially in older Hindu sacrifice. The gods are generally benevolent and friendly toward men who follow *ṛta,* and they punish their own enemies and those of the world order, which in India, too, embraces the social ethical rules.

The concept of Tao is of great importance in Chinese religion, especially in Taoism, founded by Lao-tzu according to tradition in the 6th century BC. Lao-tzu is the author of the *Tao-te Ching* ("Classic of the Way and Its Power") in which he expounds this concept in a manner that is more mystical than philosophical. Tao, literally translated "road," is a difficult and complex concept. It certainly represents the cosmic order, but in Taoism it is even more than that. It is also the concept that gives existence meaning; it is the primeval power that forms the foundation of all that is; and, in some cases, it is even used to designate some kind of high god. Taoism is a mystic religion, and the *Tao-te Ching* is a mystic treatise in which the essence of the Tao is expounded in many parables and metaphors because it cannot be expressed rationally.

Many related concepts exist. The Greek Moira, for instance, is comparable to Asha and *ṛta;* it lacks, however, the mystic overtones of Tao. The Moira in classical Greek religion is not yet fate as this idea was found in Greco-Roman times. The concept of cosmic order may function either in a religious or in a philosophic context; *e.g.,* the pre-established harmony (*harmonia praestabilita*) in the philosophy of Gottfried Wilhelm Leibniz, a German Rationalist, is the cosmic order that holds together and unifies the innumerable individual units, called monads by Leibniz.

Particular objects of Providence. Although cosmic order is necessarily a general idea comprising the whole of the world and all that exists in it, the concept of Providence may be more particular: the benevolent aspect of Providence may be confined to a special group of people or at least be specially related to that group; or a number of patron gods or saints may watch over some specific activity or smaller group. This accounts for the idea of a chosen people watched over and led by a just and loving God. The ancient people of Israel is, perhaps, the best known example; the concept, however, is widespread. Patron gods and patron saints who are particularly charged with caring for some small group, craft, or activity or who operate in special circumstances, such as during illness or war, occur in most religions and are popular in many.

Although Providence in most religions operates primarily for the welfare and the salvation of the community as a whole, it may also be experienced as personal guidance. This latter phenomenon is common in some diverse cultures—*e.g.,* that of the Plains Indians of North America and in some forms of Protestantism in which generally each person is expected to have a private experience of divine guidance. In other cultures and religions, personal guidance is often a prerogative of some person or persons singled out for some reason by God or the gods.

CRITICAL PROBLEMS

It is clear that the concept of Providence by its central position in many religions is connected with numerous other aspects of religion. In monotheistic religions Providence is a quality of the one divinity; in polytheistic religions it may be either a quality of one or more gods or it may be conceived as an impersonal world order on which the gods, too, more or less depend. In the latter case, Providence may lose its aspect of benevolence and become inexorable fate or fickle chance. Most religions show a certain ambivalence; for fate and Providence do not always form a clear-cut contradiction.

Still another form of ambivalence occurs between fate or divine will and the will of man when the latter is conceived as free, or at least free to a certain degree. In some religions the benevolent aspect of Providence appears as grace, and a discussion may arise about the relationship between free will and grace. Perhaps the most difficult problem connected with the notion of Providence is the existence of evil; men have perennially coped with the question of how to reconcile the idea of a provident God or gods with the evident existence of evil in the world. (T.P.v.B.)

The problem of evil

Revelation

Revelation is a religious term that designates the disclosure of divine or sacred reality or purpose to men. In the religious view, such disclosure may come through mystical insights, historical events, or spiritual experiences that transform the lives of individuals and groups.

NATURE AND SIGNIFICANCE

Every great religion acknowledges revelation in the wide sense that its followers are dependent on the privileged insights of its founder or of the original group or individuals with which the faith began. These profound insights into the ultimate meaning of life and the universe, which have been handed down in religious traditions, are arrived at, it is believed, not so much through logical inference as through sudden, unexpected illuminations that invade and transform the human spirit. Those religions that look upon God as a free and personal spirit distinct from the world accept revelation in the more specific sense of a divine self-disclosure, which is commonly depicted on the model of human intersubjective relationships. In the "prophetic" religions (Judaism, Christianity, Islām, and Zoroastrian-

ism), revelation is conceived as a message communicated by God to an accredited spokesman, who is charged to herald the content of that message to an entire people. Revelations received on behalf of the whole community of the faithful are often called "public" (as opposed to "private" revelations, which are given for the guidance or edification of the recipient himself).

The media of revelation

The media by which revelation occurs are variously conceived. Most religions refer to signs, such as auditory phenomena, subjective visions, dreams, and ecstasies. In primitive religions, revelation is often associated with magical techniques of divination. In the prophetic religions, revelation is primarily understood as the "Word of God," enabling the prophet to speak with certainty about God's actions and intentions. In mystical religion (*e.g.*, Islāmic Ṣūfism, Tantric Buddhism) revelation is viewed as an ineffable experience of the transcendent or the divine.

TYPES AND VARIATIONS

Religions of nonliterate cultures. In nonliterate culture revelation is frequently identified with the experience of supernatural power (mana) in connection with particular physical objects, such as stones, amulets, bones of the dead, unusual animals, and other objects. The sacred or holy is likewise believed to be present in sacred trees, groves, shrines, and the like and in elemental realities such as earth, water, sky, and the heavenly bodies. Once specified as holy, such objects take on symbolic value and become capable of mediating numinous (spiritual) experiences to the adherents of a cult. Certain charismatic individuals, such as shamans, who are believed to be in communion with the sacred or holy, perform functions akin to those of the prophet and the mystic in more developed religions.

Religions of the East. Eastern religions are concerned with man's struggle to understand and cope with the predicament of his existence in the world and to achieve emancipation, enlightenment, and unity with the Absolute. Western religions, on the other hand, lay more stress on man's obedient response to the sovereign Word of God. The notion of revelation in the specific sense of a divine self-communication is more apparent in Western than in Eastern religions.

Hinduism. In Hinduism, the dominant religion of India, revelation is generally viewed as a process whereby the religious seeker, actuating his deeper spiritual powers, escapes from the world of change and illusion and comes into contact with ultimate reality. The sacred books are held to embody revelation insofar as they reflect the eternal and necessary order of things.

A major form of Hindu thought, Vedānta, includes two main tendencies: the monistic (*advaita*) and the theistic (*bhakti*). The leading sage of Advaita Vedānta, Śaṅkara (early 9th century), while acknowledging in principle the possibility of coming to a knowledge of the Supreme Reality (Brahman) through inner experience and contemplation of the grades of being, held that in practice a vivid apprehension of the divine arises from meditation on the sacred books, especially the *Upaniṣads*. In Bhakti, systematized by the philosopher Rāmānuja (*c.* 1050–1137), the Absolute is regarded as personal and compassionate. Revelation, consequently, is viewed as the gracious self-manifestation of the divine to those who open themselves in loving contemplation. The devotional theism of Bhakti, very influential in modern India, resembles the pietism and mysticism of the Western religions.

Buddhism. Buddhism, the other great religion originating on Indian soil, conceives of revelation not as a personal intervention of the Absolute into the worldly realm of relativities but as an enlightenment gained through discipline and meditation. Gautama the Buddha (6th to 5th century BC), after a striking experience of human transitoriness and a period of ascetical contemplation, received an illumination that enabled him to become the supreme teacher for all his followers. Although Buddhists do not speak of supernatural revelation, they regard the Buddha as a uniquely eminent discoverer of liberating truth. Some venerate him, some worship him, and all Buddhists seek to imitate him as the most perfect embodiment of ideal manhood—an ideal that he in some way "reveals."

Role of the Buddha

Chinese religions. Chinese wisdom, more world-affirming than the ascetical religions of India, accords little or no place to revelation as this term is understood in the Western religions, though Chinese traditions do speak of the necessity of following a natural harmony in the universe. Taoism, perhaps the most characteristic Chinese form of practical mysticism, finds revelation only in the transparency of the immanent divine principle or way (Tao). Confucianism, while not incompatible with Taoism, is oriented less toward natural mysticism and more toward social ethics and decorum, though it too is concerned with accommodating life to a balance in the natural flow of existence. Confucius (551–479 BC), who refined the best moral teachings that had come down in the tradition, was neither a prophet appealing to divine revelation nor a philosopher seeking to give reasons for his doctrine.

Religions of the West. In the three great religions of the West—Judaism, Christianity, and Islām—revelation is the basic category of religious knowledge. Man knows God and his will because God has freely revealed himself—his qualities, purpose, or instructions.

Judaism. The Israelite faith looked back to the Pentateuch (the first five books of the Old Testament) for its fundamental revelation of God. God was believed to have revealed himself to the patriarchs and prophets by various means not unlike those known to the primitive religions —theophanies (visible manifestations of the divine), dreams, visions, auditions, and ecstasies—and also, more significantly, by his mighty deeds, such as his bringing the Israelites out of Egypt and enabling them to conquer the Holy Land. Moses and the prophets were viewed as the chosen spokesmen who interpreted God's will and purposes to the nation. Their inspired words were to be accepted in loving obedience as the Word of God.

Revelation through events

Rabbinic Judaism, which probably originated during the Babylonian Exile and became organized after the destruction of the Temple by the Romans, concerned itself primarily with the solution of legal and ethical problems. It gradually developed an elaborate system of casuistry resting upon the Torāh (the Law, or the Pentateuch) and its approved commentaries, especially the Talmud (commentaries on the Torah), which was regarded by many as equal to the Bible in authority. Orthodox Judaism still recognizes these authoritative sources and insists on the verbal inspiration of the Bible, or at least of the Pentateuch.

Christianity. The New Testament took its basic notions of revelation from the contemporary forms of Judaism (1st century BC and 1st century AD)—*i.e.*, from both normative rabbinic Judaism and the esoteric doctrines current in Jewish apocalyptic circles in the Hellenistic world. Accepting the Hebrew Scriptures as preparatory revelation, Christianity maintains that revelation is brought to its unsurpassable climax in the person of Jesus Christ, who is God's own Son (Heb. 1:1–2), his eternal Word (John 1:1), and the perfect image of the Father (Col. 1:15). The Christian revelation is viewed as occurring primarily in the life, teaching, death, and Resurrection of Jesus, all interpreted by the apostolic witnesses under the illumination of the Holy Spirit. Commissioned by Jesus and empowered by the divine spirit, the apostles, as the primary heralds, hold a position in Christianity analogous to that of the prophets in ancient Israel.

The Apostle Paul, though not personally a witness to the public life of Jesus, is ranked with the Apostles by reason of his special vision of the risen Christ and of his special call to carry the Gospel to the Gentiles. In his letters, Paul emphasized the indispensability of missionary preaching in order that God's revelation in Christ be communicated to all the nations of the world (Rom. 10:11–21).

Christianity has traditionally viewed God's revelation as being complete in Jesus Christ, or at least in the lifetime of the Apostles. Further development is understood to be a deeper penetration of what was already revealed, in some sense, in the 1st century. Periodically, in the course of Christian history, there have been sectarian movements that have attributed binding force to new revelations occurring in the community, such as the 2nd-century Montanists (a heretical group that believed they were of the Age of the Holy Spirit), the 13th century Joachimites (a

mystical group that held a similar view), the 16th-century Anabaptists (radical Protestant sects), and the 17th-century Quakers. In the 19th century the Church of Jesus Christ of Latter-day Saints (popularly known as Mormons) recognized, alongside the Bible, additional canonical scriptures (notably, the Book of Mormon) containing revelations made to the founder, Joseph Smith.

Islām. Islām, the third great prophetic religion of the West, has its basis in revelations received by Muḥammad (*c.* 7th century AD). These were collected shortly after his death into the Qur'ān (Koran), which is regarded by Muslims as the final, perfect revelation—a human copy of the eternal book, dictated to the Prophet. While Islām accords prophetic status to Moses and Jesus, it looks upon the Qur'ān as a correction and completion of all that went before. More than either Judaism or Christianity, Islām is a religion of the Book. Revelation is understood to be a declaration of God's will rather than his personal self-disclosure. Insisting as it does on the absolute sovereignty of God, on man's passivity in relation to the divine, and on the infinite distance between creator and creature, Islām has sometimes been inhospitable to philosophical speculation and mystical experience. Yet in medieval Islām there was both a remarkable flowering of Arabic philosophy and the intense piety of the mystical Ṣūfīs. The rationalism of some philosophers and the theosophical tendencies of some of the Ṣūfīs came into conflict with official orthodoxy.

Revelation through a sacred book

Zoroastrianism. A fourth great prophetic religion, which should be mentioned for its historic importance, is Zoroastrianism, once the national faith of the Persian Empire. Zoroaster (Zarathushtra), a prophetic reformer of *c.* 7th century BC, apparently professed a monotheistic faith and a stern devotion to truth and righteousness. At the age of 30 he experienced a revelation from Ahura Mazdā (The Wise) and chose to follow him in the battle against the forces of evil. This revelation enabled Zoroaster and his followers to comprehend the difference between good (Truth) and evil (The Lie) and to know the one true God. Later forms of Zoroastrianism apparently had an impact on Judaism, from the time of the Babylonian Exile, and, through Judaism, on Christianity.

THEMES AND FUNCTIONS

Recurrent questions concerning revelation include the relationship between general and special revelation; the relationship between word and deed as media of special revelation; the authority of the sacred books; the revelatory value of tradition; the nonverbal component in revelation; the interpersonal dimension of revelation; and the relationship between faith and reason.

General revelation: the role of nature. The Eastern religions, on the whole, differ from Western religions in that they place less emphasis on a special or exclusive revelation received by a "chosen people" and rather speak of the manifestation of the Absolute through the general order of nature. There is, however, no irreconcilable opposition between general and special revelation. Vedānta Hinduism and Buddhism, even if they do not speak of special revelation, believe that their religious books and traditions have unique value for imparting a saving knowledge of the truth. The Bible and the Qur'ān, conversely, proclaim that although God has specially manifested himself to the biblical peoples, he also makes himself known through the order of nature. The failure of some nations to acknowledge the one true God is attributed not to God's failure to disclose himself but rather to the debilitating effects of sin on the perceptive powers of man.

Special revelation: the role of history. The Western religions differ somewhat among themselves in the ways in which they understand how special revelation occurs. Some focus simply on the direct inspiration of the divinely chosen prophets. The Judeo-Christian tradition, however, characteristically looks upon the prophets as witnesses and interpreters of what God is doing in history. Revelation through deeds is conceived to be more fundamental than revelation through words, though the words of the prophets are regarded as necessary to clarify the meaning of the events. Since the Old Testament term for "word" (*davar*) signifies also "deed" or "thing," there is no clear line of demarcation between word-revelation and deed-revelation in the Bible. The biblical authors look upon the national fortunes of Israel as revelations of God's merciful love, his fidelity to his promises, his unfailing power, his exacting justice, and his readiness to forgive the penitent sinner. The full disclosure of the meaning of history, for many of the biblical writers, will occur only at the end of time, when revelation will be given to all peoples in full clarity. The Judeo-Christian notion of history as progressive revelation has given rise to a variety of theological interpretations of world history, from St. Augustine (AD 354–430) to G.W.F. Hegel (1770–1831) and other modern thinkers.

Revelation and sacred scriptures. In those religions that look for guidance to the ancient past, great importance is attached to sacred books. Theravāda Buddhism, while it professes no doctrine of inspiration, has drawn up a strict canon (standard or authoritative scriptures)—the "Pāli canon"—in order to keep alive what is believed to be the most original and reliable traditions concerning the Buddha. Mahāyāna Buddhism, while it has no such strict canon, considers that all its adherents must accept the authority of the *sūtras* (basic teachings written in aphorisms). Zen Buddhism, in many ways the broadest development of Mahāyāna thought, sometimes goes to the point of rejecting any such written authority. Many religions view their holy books as inspired and inerrant. According to a very ancient Hindu tradition, the sages of old composed the Vedas by means of an impersonal type of inspiration through cosmic vibrations. Judaism, on the other hand, looks upon the Bible as divinely inspired. The idea of verbal dictation from God, which occurs here and there in the Bible, was applied by some rabbis to the Pentateuch, which was believed to have been written by Moses under verbal inspiration, and even to the whole Bible. Christianity, which generally accepts both the Old and New Testaments as in some sense inspired, has at times countenanced theories of verbal dictation. According to the Mormons, the Book of Mormon was composed in heaven and delivered on tablets of gold to Joseph Smith. Islām holds that the Qur'ān, an eternal heavenly book, was dictated verbatim to Muḥammad. The Prophet's companions testified that he would often turn red or livid, sweat profusely, and fall into trances while receiving revelations.

The importance of canons of scriptures

Revelation and tradition. The great religions frequently make a distinction between those scriptures that contain the initial revelation and others, at the outer fringe of the canon, that contain authoritative commentaries. In Hinduism, the four Vedas and three other ancient collections—the *Brāhmaṇas*, *Āraṇyakas*, and *Upaniṣads*—are *Śruti* ("that which has been heard"; *i.e.*, constitutive revelation); the other sacred writings (the *sūtras*, the law-books, *Purāṇas*, and the *Bhagavadgītā* and the *Rāmāyaṇa*, the two great epics) are *Smṛti* ("that which has been remembered"; *i.e.*, tradition). Later Judaism, while recognizing the unique place of the Bible as the written source of revelation, accords equal authority to the Talmud as traditional commentary. Among Christians, Roman Catholics and the Eastern Orthodox believe that revelation is to be found not only in the Bible but also, by equal right, in the apostolic tradition. Protestants emphasize the objective sufficiency of Scripture as a source of revelation, but many Protestants today are careful to add that Scripture must always be read in the light of church tradition in order that its true message be rightly understood. Islām holds that the Qur'ān alone contains revelation in the strict sense (*waḥy*), but it accepts tradition (*Ḥadīth*) as a supplementary source of Islāmic law. Special significance is attached to the practice (*sunnah*) of the Prophet himself and to the traditions handed down by his immediate companions.

Apostolic tradition

Revelation and experience. In most religions nonverbal communication plays an important part in the transmission of revelation. This can occur in art (notably in icons, statues, and idols), in sacred music, in the liturgy, and in popular dramas, such as the mystery plays common in medieval Europe or those still performed in Indian villages. For a deeper initiation into the revelation, it is believed

necessary to live under the tutelage of a guru (teacher), monk, or holy man. To the extent that revelation is identified with a profound and transforming personal experience, the spiritual preparation of the subject by prayer and asceticism is stressed. Among the great living religions of the world, there is wide agreement that revelation cannot be fully communicated by books and sermons but only by an ineffable, suprarational experience. In Hinduism the *Upaniṣad*s emphasize the hiddenness of God. Leaving behind all created analogies, the adept is led to the point where he comes to praise God in an adoring silence more exalted than speech. Buddhism of the Mahāyāna, especially its Zen varieties, likewise advocates ecstatic contemplation.

The Eastern mystics are here in close agreement with the Jewish Ḥasidim (mystical pietists), with the Islāmic Ṣūfīs, and with the great Christian mystics, such as Pseudo-Dionysius, the Areopagite, Meister Eckehart, and St. John of the Cross. Many theologians within Judaism (*e.g.*, Maimonides) and Eastern Christianity (*e.g.*, St. John Chrysostom, St. John of Damascus) have contended that God is best known through a negative, or "apophatic," theology that makes no positive statements about God. This idea, never absent from the medieval scholastic (intellectualist) tradition, was newly emphasized by Martin Luther, who insisted that the revealed God (*Deus revelatus*) remains the hidden God (*Deus absconditus*), before whom man must stand in reverent awe. Contemporary Roman Catholic theologians, such as Karl Rahner, maintain that even in heaven God will not cease to be, for man's finite mind, an unfathomable mystery. Revelation makes man constantly more aware of the depths of the divine incomprehensibility.

The revealed God as the hidden God

Revelatory relationships. In certain forms of mysticism, particularly prevalent in the Eastern religions, the envisioned goal is an absorption into the divine, involving the loss of individual consciousness. In the Western religions and in Bhakti Hinduism the abiding distinctness of the individual personality is affirmed. Islāmic orthodoxy, looking upon revelation as a declaration of the divine will, stresses not so much the communion of man with God as rather man's obedient submission to the creator. Islāmic Ṣūfism, however, resembles Ḥasidic Judaism and Christianity in its aspiration for personal union with God. For many contemporary religious thinkers, such as the Jewish philosopher Martin Buber and the Roman Catholic philosopher Gabriel Marcel, revelation involves a mutual self-giving of the revealer and the believer in personal intercommunion. According to Karl Rahner, revelation consists primarily and essentially in God's gracious communication of his own divine life to man as a personal spirit. In his view, the articulation of revelation in the scriptures and creeds is a secondary stage, presupposing an experiential encounter with the divine. This secondary phase, however, is viewed as necessary in order that man may realize himself in his humanity as a believer and achieve solidarity with his fellow believers. In general, the Western religions tend to attach more importance to the idea of a community of faith than do the Eastern religions. Revelation in the biblical and Islāmic view is addressed not to individuals as such but to a whole people, which achieves its identity, in part, by articulating its faith in writings that are approved as authentic expressions of what God has revealed.

Revelation and reason. The problem of the relationship between revelation and reason arises, on the one hand, because revelation transcends the categories of ordinary rational thought and, on the other hand, because revelation is commonly transmitted by means of authoritative records, the contents of which cannot be verified by the believer. Buddhism, since it does not attribute inspiration or inerrancy to its canonical sources, allows some scope for individual reason to criticize the authoritative writings, but, like other religions, it has to face the charge that the illumination to which it aspires may be illusory. Orthodox Hindus, giving full authority to the Veda, hold that human reason errs whenever, on the grounds of perceptual experience, it takes issue with the sacred writings. Hinduism, however, allows for great freedom in the exegesis (interpretation) of its sacred books, some of which are more poetic than doctrinal.

The tension between faith and reason has been particularly acute in the Western religions, which find revelation not simply in holy books but in prophetic words that call for definite assent and frequently command a precise course of action. The ambiguities of scripture in these religions are frequently cleared up by creeds and dogmas of the community, calling for the assent of true believers. Judaism, Christianity, and Islām, moreover, came into close contact with Hellenistic culture, which held up the ideal of rationally certified knowledge as the basis for the good life. They, therefore, had to face the problem: could assent to an authoritative revelation be justified before the bar of reason? Some theologians took a "fideist" (faith-based) position, maintaining that reason must in all things submit to the demands of revelation. Others, such as the Arabic philosopher Averroës and his followers (both Muslim and Christian), accepted the primacy of reason. They reinterpreted the content of revelation so as to bring it into line with science and philosophy. A third school, in which the medieval Jewish philosopher Maimonides and the medieval Christian scholastic theologian Thomas Aquinas may be included, sought to maintain the primacy of faith without sacrificing the dignity of reason. According to the Thomist theory, human reason can discern the credibility of revelation because of the external signs by which God has authenticated it (especially prophecies and miracles). Reason, moreover, makes it possible for the believer to understand, in some measure, the revealed mysteries. This intellectualist position continues to appeal to many Christians; but some maintain that it overlooks the qualitative differences between faith—as a transrational assent to mystery—and scientific knowledge, which operates within the categories of objectivizing reason.

Tension between faith and reason

CONCLUSION

In some theological circles the concept of revelation is rejected on the ground that it is bound up with mythological and anthropomorphic conceptions and introduces an unassimilable element into the history of religions. It would seem, however, that the concept can be purified of these mythical elements and still be usefully employed. In the sphere of religion, wisdom is often best sought through privileged moments of ecstatic experience and through the testimony of those who have perceived the sacred or holy with unusual purity and power. The self-disclosure of the divine through extraordinary experiences and symbols is fittingly called revelation. Because of the pervasiveness of the idea of revelation in the world's religions and because the various religions have had to cope with similar theological problems concerning revealed knowledge, revelation has become a primary theme for dialogue among the great religions of mankind. (A.Du.)

Perception of the sacred or holy

Covenant

The concept of covenant—that is, a binding promise—is of far-reaching importance in the relations between individuals, groups, and nations. It has social, legal, religious, and other aspects. This section is concerned primarily with the term in its special religious sense and especially with its role in Judaism and Christianity.

NATURE AND SIGNIFICANCE

Covenants in the ancient world were solemn agreements by which societies attempted to regularize the behaviour of both individuals and social organizations, particularly in those contexts in which social control was either inadequate or nonexistent. Though ancient pre-Greek civilizations apparently never developed a descriptive theory of covenants, analysis of covenant forms and the ancient use of language yields a definition that essentially is the same as that found in modern law. It is a promise or agreement under consideration, usually under seal or guarantee between two parties, and the seal or symbol of guarantee is that which distinguishes covenant from modern contract.

Definition of covenant

The concept of covenant has been of enormous importance in the biblical tradition; from it there is derived the

long traditional division of the Bible into the Old and New Testaments (Covenants). In postbiblical Judaism and sporadically in Christianity, the concept of covenant has been a major source and foundation of religious thought and especially of the concept of the religious community, but the nature and content of covenant ideas have undergone an extremely complex history of change, adaptation, and elaboration.

Though both covenant and law in the ancient world were means by which obligation was both established and sanctioned, and are often virtually identified with each other in modern scholarly literature, there are, nevertheless, very important contrasts between the two that should not be obscured. A covenant is a promise that is sanctioned by an oath. This promise in turn was accompanied by an appeal to a deity or deities to "see" or "watch over" the behaviour of the one who has sworn, and to punish any violation of the covenant by bringing into action the curses stipulated or implied in the swearing of the oath. Legal procedure, on the other hand, may be entirely secular, for law characteristically does not require that each member of the legal community voluntarily swear an oath to obey the law. Further, in ordinary legal procedure the sanctions of the law are carried out by appropriate agencies of the society itself, not by transcendent powers beyond the control of man and society.

Because a person can bind only himself by an oath, covenants in the ancient world were usually unilateral. In circumstances in which it was desirable to establish a parity (equivalence) treaty, such as in rare cases in political life, the parity was obtained by the simple device of what might be termed a double covenant, in which both parties would bind themselves to identical obligations, and neither was therefore subjected to the other.

The oath was usually accompanied by a ritual or symbolic act that might take any of an enormous range of forms. One of the most frequent of these was the ritual identification of the promisor with a sacrificial animal, so that the slaughter and perhaps dismemberment of the animal dramatized the fate of the promisor if he were to violate the covenant.

ORIGIN AND FUNCTION OF COVENANTS

Origins. That covenants most probably originated in remote prehistoric times is indicated by the fact that they were already well-developed political instruments by the 3rd millennium BC. To judge from later parallels and from the modern observations of anthropologists, covenants may very well have developed at least in part out of marriage contracts between exogamous tribes or bands; *i.e.*, those groups that stayed within the required patterns of intermarriage. Whether or not this was the case, the most important functions of covenants for 1,000 years before the 13th-century BC Sinai covenant (see below) had to do with the creation of new relationships, both familial and political. Though the old theory of "social contract"—*i.e.*, the basic agreement about the social and political order—as the basis of large social organizations has not for some time been much in favour among social scientists, very early historical evidence seems increasingly to suggest that covenants may have been much more instrumental in society than has been realized.

Early functions of covenants

Typically, so far as existing sources now reveal, a covenant between social groups regularized in advance the relationships between two societies after one had been subjugated by a superior coercive force, usually by military action or the threat thereof. In the Mari documents (18th-century-BC archives from the palace at Mari in Syria), such a covenant was called a *salimum*, a "peace," probably because the promises made by the vanquished brought to an end the necessity of military operations against the vassal ruler or state. As is the case throughout so much of human history, ancient states characteristically seem to have regarded their neighbours as either enemies or vassals. Thus it is not surprising that covenants made under duress had little vitality, particularly when the terms of the covenant called for a considerable annual tribute to the overlord state.

Late Bronze Age developments. About the beginning of the late Bronze Age (*c.* 1500 BC), there occurred a major step forward in both the form and the concept of political covenants as is attested by treaties of the Hittite Empire of Asia Minor. Though the realities of political life were probably little changed, since the foreign policy of the Hittite Empire was primarily military, the structure of suzerainty treaties from this time on included rather strenuous efforts to demonstrate that the vassal's obligations to the Hittite overlord were really founded upon the former's self-interest, not merely upon the brute military force of the latter.

Hittite treaties

By far the most evidence for international treaties in the ancient world comes from Hittite sources, which were contemporary with the events that preceded and led up to the formation of the ancient Israelite federation of tribes in Palestine. The treaty form in written texts was highly developed and flexible but usually exhibited the following structure: preamble, historical prologue, stipulations, provisions for deposit and public reading, witnesses, and curses and blessings formulas. (1) The preamble names the overlord who grants the treaty-covenant to the vassal. The titles and laudatory epithets of the Great King are also given. (2) The historical prologue describes the previous relationships between the two parties in some detail, usually emphasizing the benevolent acts of the Great King toward the vassal. Thus the covenant is based upon the demonstrated benefits that have already been received and therefore holds out the expectation of continuing advantage for faithful obedience to the covenant. There is an implication that obedience to obligations is based upon gratitude. (3) The stipulations, which in form are much like those of the ancient Mesopotamian law codes (case law), define in advance the obligation of the vassal in certain circumstances. In addition, there are also generalized statements of obligation of a type that has been called "apodictic law" (regulations in the form of a command). The obligations deal particularly with military assistance, the treatment of fugitives, and foreign policy. Treaty relationships with other independent states are a violation of covenant. (4) Provision is made for deposit of the treaty in the temple and for periodic public reading. Because the temple is the "house of the god," the written document was placed there for the watchful attention of the deity. The treaty obligations, however, were also binding upon the vassal's citizenry, and so at stipulated intervals the text was read to the assembly, both as a reminder and a warning. (5) The list of witnesses included, in addition to the major deities of both states, deified elements of the natural world, such as mountains, rivers, heaven and earth, winds, and clouds. The witnesses were those powers that were believed to be beyond human control and upon which man and society were regarded as completely dependent. They were invoked to apply the appropriate sanctions of the covenant. (6) The curses and blessings formulas are the sanctions that furnish not only negative but also positive motivations for obedience. They include the natural and historical calamities beyond human control, such as disease, famine, death without posterity, and destruction of the society itself. The blessings are of course the opposite: prosperity, peace, long life, continuity of kingship and society.

In view of the obsession with rituals that characterized Hittite culture, some elaborate ceremony probably accompanied the ratification of covenant, such as the account of one preserved in the document known as "The Soldiers' Oath," but it is not described in existing covenant texts.

Scholars in Europe and America in the 20th century have seen an astounding similarity between this treaty structure and the biblical traditions of the Sinai covenant. Publication of texts in the mid-1950s was followed by an enormous amount of scholarly discussion, but as yet no conclusions can be said to represent a scholarly consensus. The formal similarity to biblical traditions cannot be denied, but the problem of what historical conclusions can be drawn from the formal similarities is highly sensitive and controversial. While the following synthesis is a probable, and historically plausible, interpretation, it must be admitted that other possibilities can by no means be excluded.

THE ORIGIN AND DEVELOPMENT OF BIBLICAL COVENANTS: JUDAISM

The Sinai covenant. *Historical background.* The 100 years between 1250 and 1150 BC saw the complete destruction, or reduction to virtual impotence, of every major political state in the eastern Mediterranean region and the beginning of a "dark age" that has yielded very few written materials from which historical conclusions can be drawn. The reasons for the universal catastrophe are far from clear, but the reversion of society to communities of peasants and shepherds with a subsistence level economy can be well illustrated archaeologically. The earliest biblical traditions illustrate the conditions in Palestine at this time, though it is a difficult task to distinguish genuine ancient traditions from the use of the past by biblical writers to give religious validity to social realities or institutions of much later date.

In view of the highly elaborate social structure of the old Bronze Age states—with its apex in the military aristocracy, a highly complex priesthood, and ritual—and the equally complex social structure of the many local enclaves and tribes—each with its particular god—the monotheistic and ethically centred religious ideology of early Israel has been regarded for millennia as a miracle of "revelation," which cannot be explained on the basis of usual historical principles and concepts. Yet, ancient Israel was an historically existent community created, and precariously maintained, by a unity of which the religious ideology was the foundation for two centuries, until military considerations resulted in the formation of a political centralization of power about 1000 BC. The covenant tradition is the only instrument by which the effective functioning of that unity can be understood, and its importance is underlined by the biblical traditions themselves. The structure of the Hittite treaties now makes available an historical precedent that enables scholars to understand the structure of early Israelite thought and consequently its functional operation in history.

The covenant tradition as an instrument of unity

The covenant at Sinai. The Decalogue (The Ten Commandments) given by Yahweh, the God of the Israelites, at Sinai, plus the various traditions associated with earliest Israel yield all of the important elements of the Hittite treaty form but in an extremely succinct and simple form. Yahweh is identified as the covenant giver, and the historical prologue is the only possible one according to the ancient traditions: the announcement that it is this God who delivered the assembled group from bondage in Egypt (in the 13th century BC). This delivery is a free, voluntary act of the deity that forms the basis of the obligations that the community can either accept together with a lasting relationship to that God or reject, thus entailing a permanent hostility (hatred) between the God and human beings. It is the common relationship to a single sovereign God that furnished the basis for a radically new kind of community, which grew with rapidity first in Transjordan, then in Palestine proper, until it included virtually all the nonurban population of the region.

The new community was the answer, temporarily at least, to the old dilemma of civilization: how to maintain peace among a large and diverse population, perform the necessary social functions of cooperation and protection, and control individual attacks upon the security and property of others without the enormous and expensive paraphernalia of political bureaucracy, military machine, and the ruinous tax collector. It was, for all functional purposes, the Kingdom (or Rule) of Yahweh, which excluded the deification of any other factor in human history or nature that was of importance to human life and well-being. The Sinai covenant marked the beginnings of nearly all the various theological themes that were to be so greatly elaborated upon in the following millennia: the Providence, or Grace, of God; the Kingdom of God; the sin of man and the wrath of God; the Holy People as the community of God; the rewards and punishments of the obedient and the disobedient respectively; and above all, the ethical norms as the essence of divine command over against the universal pagan obsession with proper ritual as the normative expression of man's subjection to the divine will.

The Sinaitic covenant stipulations may be expressed in modern functional terms in the following manner: (1) The commandment to have no other gods involves the obligation to refuse subjection to all other social and human concerns and their symbolization in art forms so as to give them a position of parity or superiority to Yahweh and his commands. (2) The commandment not to take the name of God in vain emphasizes the unconditional sanctity of oaths that Yahweh was called upon to guarantee and enforce. (3) The commandment to observe the Sabbath, the seventh day, the original social function of which is still unknown, could very well have grown out of a common village custom, for even in Rome in the 1st century BC, good farming practice permitted work animals and slaves to rest every eighth day—and this is precisely the interpretation given in Deut. 5:14. (4) The commandment to honour father and mother emphasizes the treatment of parents with respect and deference, which must have been of particular importance in a time of social upheaval and polarization. (5) The commandment not to kill meant that killing of persons by persons, even by accident if it involved negligence, was a usurpation of the divine sovereignty over persons. Contrary to modern reinterpretations, among opponents of capital punishment and pacifists, this could not include execution of persons for crime or killing of the enemy in warfare, for in both cases human beings were acting as the agents of Yahweh under divine command, just as the various officials of states have long carried out similar functions without incurring personal guilt for their acts. (6) Other commandments against theft, adultery, and false witness categorically prohibit acts that call into question the security of property, of family relationships and true lineal succession, and the integrity and therefore the justice of juridical procedures in society. (7) Finally, the prohibition of coveting what one's neighbour has excludes an enormous range of social attitudes and motivations that modern man now takes for granted as normal, if not essential.

Modern functional equivalents of the Ten Commandments

Most, if not all, of the Ten Commandments are ethical obligations of which violations are very difficult if not impossible for society to detect, much less to enforce or punish. The Sinai covenant, therefore, marked the beginnings of a systematic recognition that the well-being of a community cannot be based merely upon socially organized force, nor can the political power structure be regarded, as in ancient pagan states, as the manifestation of the divine, transcendent order of the universe.

The Ten Commandments as ethical obligations

Post-Sinai covenants. Traces remain in the biblical traditions to indicate that the new community formed from a "rabble" at Sinai was in very short time joined by a considerable part of the population of Transjordan and Palestine proper. After the destruction (in the late 13th century) of the military chiefdoms ruled by Sihon and Og in the area east of the Jordan River, the Hebrews held a covenant ceremony at Shittim (northeast of the Dead Sea), which has been greatly elaborated upon in tradition as the "second giving of the Law," Deuteronomy. Though it is true that the Book of Deuteronomy from the 7th century BC exhibits the same basic structure as that of the old covenant form, it is at present impossible to reconstruct the original form or content of the Shittim covenant. It may be presumed that entry into the community by covenant was followed by the allotment of land as tenured fiefs from Yahweh and the organization of the population into "tribes." This organization probably was the last event of the Hebrew leader Moses' life, and the sequel in the more important covenant at Shechem (northwest of the Dead Sea) took place under the leadership of Joshua, the successor of Moses.

Shechem evidently had had an important covenant tradition long before Israel existed. The name of its god, Baal Berit ("Lord of the Covenant"), presupposes some kind of covenant basis for the local social structure, just as a considerable segment of the population can be shown to have originated from Anatolia.

The Shechem covenant narrative has been preserved at least in part in Joshua, in which Joshua appeals to the family and clan heads to choose between the new dominion of Yahweh and the continuation of the old ancestral cults of the Amorite tradition "beyond the River." As

The Shechem covenant

in the case of the Transjordan covenant at Shittim, this covenant followed the defeat of a coalition of petty kings and evidently the removal of many others according to the list of Joshua. Again, there ensued an allotment of fields and an organization of the population into administrative units called "tribes," each under a *nasi* (literally, "one lifted up").

The entire process from the covenant at Sinai to the unification of perhaps a quarter of a million people by a covenant involving a religious loyalty to a single deity took only a little over one generation. It began with a group of probably considerably less than 1,000 people who left Egypt with Moses.

The subsequent history of the Sinai covenant tradition is very complex. The Book of Deuteronomy preserves slight traces of a covenant-renewal ceremony held every seven years, which is inherently plausible and which would function as a means for obtaining the oath-bound loyalty to Yahweh and his dominion of those who had come into the community from the outside or who had come of age in the intervening period.

The covenants of the Israelite monarchy (1020–587/586 BC). Since early Israel was a religious confederacy of tribes that bitterly rejected the old military chiefdoms and their religious ideology, which elevated a Baal, or local agricultural deity—the god with the club as a symbol of the supernatural power undergirding the king—to a position of preeminence in the pantheon, it follows that the authentic Yahwist traditions stemming from Moses could not furnish a religious ideology to legitimize the monarchy when it was finally established first under Saul (reigned *c.* 1020–1000 BC) and then successfully under David (reigned *c.* 1000–962). Furthermore, early in David's reign, he had incorporated by military force most of the existing city-states of Palestine and Transjordan into his empire, and that population had never given up the old Bronze Age cults.

It is not surprising, therefore, that this double dilemma of the new political structure should have driven the royal bureaucracy to pre-Mosaic sources as a solution to the problem. One result was the reintroduction of the age-old pagan concept of the king as the "chosen" one of the gods and a radically different—and opposite—concept of covenant, in which it was now Yahweh, not the king or the people, who bound himself by oath. Possibly modelled after old royal covenants by which ancient pagan kings made a grant to their faithful retainers, the Davidic covenant introduced a radically different (and thoroughly pagan) element into the Mosaic tradition, and the two traditions contended with one another for the next 1,000 years.

Since the old Israel-Jacob (pre-Mosaic) traditions also could not furnish an ideological base for unifying the old Israelite and non-Israelite populations under the monarchy, pre-Mosaic epic traditions of Abraham (perhaps 19th–18th centuries BC) were appealed to to furnish the "common ancestor" symbol of unity, and the covenant tradition—no doubt, already a part of that epic—was readapted to bring it up to date. The deity (now identified with Yahweh) bound himself by oath to fulfill certain promises to Abraham, though the content of the promise, in the form now received, was by and large a description of the historical situation of the Davidic empire. Though it is difficult to see what the social or ideological function may have been, the covenant with Noah (the hero of the Flood) in Genesis exhibits the same structure. The result of all these radical changes in a very short time was a complete confusing of the religious tradition and structure and a permanent deposit of the pre-Mosaic pagan religious ideology into the biblical tradition. It seems virtually certain that the Sinai tradition was itself systematically reinterpreted in the so-called ritual decalogue of Exodus in which it is dogmatically stated that the Sinai obligations were entirely ritual in nature, rather than ethical-functional. The first tables of stone of the Ten Commandments, after all, had been "broken," which in the ancient world was a customary phrase used to indicate the invalidation of binding legal documents.

Reinterpretation of the Decalogue

The next several centuries illustrate the constant battle between the Mosaic and the reintroduced pagan elements. The prophets proclaimed and supported the disintegration (*c.* 922 BC) of the Solomonic empire into a northern (Israel) and a southern (Judah) kingdom as the divine chastisement of Yahweh for gross disobedience. Particularly in the north, which did not retain the Davidic dynasty, the prophets periodically proclaimed the necessity and inevitability of wiping out one royal dynasty after another. Elijah, a 9th-century BC rustic prophet, ridiculed the idea that the Israelites could limp along on both legs—*i.e.*, observe loyalty to both the Yahwistic and the Baal cults. Reforms were carried out occasionally, but not until the time of Josiah, the young king of Judah (late 7th century BC), and the discovery of an old copy of the Mosaic legal-ethical tradition (the Deuteronomic code) in *c.* 621 BC was serious reform undertaken—and there with little permanent success. The preservation of the Mosaic tradition was a function of the destruction of the monarchical state and its religious symbol, the temple, which nearly all the pre-exilic (before 587/586 BC) prophets had predicted.

The post-Exilic covenant tradition. Though the prophet Jeremiah (late 7th century BC) had predicted a "new covenant" written upon the heart (Jeremiah), not until the time of the prophets Ezra and Nehemiah in the 5th century is there another biblical narrative of covenant making, this time one of incalculable importance for the future of both postbiblical Judaism and Christianity and perhaps even for certain aspects of political theory or practice in the West (*e.g.*, "Covenant" of the United Nations, Mayflower Compact, and constitutions).

The account in Nehemiah is not so much that of a covenant as it is of a constitutional convention, the purpose of which was to establish as binding law the complex of traditions that had been preserved and recorded as the "law of God which was given by Moses, the servant of God" (Nehemiah). It is a one-party enactment by the authorities and representatives of the community, in which Yahweh appears only as the deity addressed in the long historical prologue in the form of a prayer. The content is a recapitulation of the Deuteronomic history (interpretations of the 7th-century BC document), narrating the benevolent acts of Yahweh and the sin and punishment of the people. In order to avoid the curses, and obtain the blessings, the community resolved henceforth to observe the "law of God." From this time on, the dominant concept of covenant in Judaism identifies it with circumcision, the ritual by which on the eighth day of his life, the male Jew becomes obligated to obey the law of Moses, the *berit* (covenant). The Sinai covenant had become permanently identified with the accumulation of legal-ritual tradition, and the community was identified not as the complex variety of all those who wished and accepted the rule of God but as the ethnic group of those who were heirs of the promise to Abraham in direct lineal (and fictitious) descent.

THE ORIGIN AND DEVELOPMENT OF THE COVENANT IN CHRISTIANITY

The New Testament tradition of the covenant. The cup of wine at the Last Supper of Jesus and his disciples before Jesus' crucifixion is identified in all New Testament sources as the (new) covenant by Jesus himself, but in spite of millennia-long controversy, theological elaboration, and discussion, the nature and meaning of the covenant has never been adequately understood historically, and the variety of interpretations regarding covenant in the New Testament itself indicates that very early in the tradition it had become a problem. Here it is possible only to indicate some significant associations that might explain why it was called a "covenant" and how the ancient Sinaitic tradition was radically renewed but the basic structure retained.

First, it has been noted that a most important aspect of covenant traditions common to most ancient cultures was the ritual identification of the oath taker with the sacrificial victim. The identification of the bread and the wine with the body and blood of Christ at the Last Supper apparently was interpreted in this sense, so that the subsequent death of the victim entails the symbolic death—the ultimate curse for breach of covenant—of all those

The death of Jesus in relation to the covenant

who were thus identified with the victim. Consequently, the curses of the law were nullified. The death of Jesus thus becomes in the Christian proclamation the centre of the historical narrative—the historical prologue of the covenant—leading up to the covenant enactment, or the *sacramentum*, to use the Latin term of the early church, which in secular use at that time meant primarily the soldier's oath of loyalty to the emperor (see above *Late Bronze Age developments*). The Christian covenant was thus a highly complex historical act that brought about a relationship of the believer to Christ whose (normally) unseen Glory was identified with that of God himself, whose Lordship was viewed as operational in history, and whose community (of believers) was identified with the Kingdom (Dominion or Rule) of God. If God in the Old Testament could rule without kings, God could, for the New Testament writers, rule without the elaborate structure of the accumulated legal traditions. They were regarded as valuable for edification and for warning but no longer as having binding validity. The anathema, or curse, was no longer tied to the definitions of legal violation but rather to rejection of God's rule in Christ. The community in turn was no longer the lineal descent group with a parochial ritual tradition but the assembly (*ekklēsia*) of those who had through the covenant accepted a relationship to the dominion of Christ.

The obligations could not, in the New Testament viewpoint, be again defined in legal terms, nor could they be enforced by social power structures, which could deal only with external formal acts, not with the basic springs of behaviour, such as love or hate. The content of obligation was thus not defined; instead, in the Sermon on the Mount (Matthew) and other New Testament literature, it is the criteria (motivations, ethical norms, personality traits) by which the rule of God is recognized upon which the emphasis falls. The presumption is that anyone who is capable of recognizing the rule of God in his experience in society will also be capable of understanding what the nature of his obligation will be in specific circumstances. The curses and blessings alike are then postponed until the final judgment. The motivations of fear of punishment and hope of reward are irrelevant to the daily routine of ethical choice, which is thus not only possible (*i.e.*, not prescribed in advance by legal definition) but unavoidable and also necessary to make responsible ethical decisions in a world that is characterized by cultural diversity and change.

The post-apostolic church. Covenant concepts in early Christian theology apparently centred on the transferrence of the Davidic covenant to the Messianic figure—*i.e.*, Christ. The fundamental theological problem of the early church was to validate the authority of Christ against both paganism and Judaism and to maintain the authority of the new religious community. After the great theologian Augustine (354–430), little attention was given to covenants until the Reformation in the 16th century. Though Luther (1483–1546) referred to and discussed the biblical covenants, it was never of particular importance to his theology. It is rather in Reformed theology, particularly that of John Calvin (1509–64) and the later Puritans of the 17th century, that its further elaboration took place. One aspect of the use of covenant may be cited in the famed Mayflower Compact of November 11, 1620 (drawn up by the Pilgrims, Separatists from the Church of England) by which a "civil body politic" was formed that would in turn enact laws and offices for the general good.

Significance of covenants in Reformed Protestant theology

The theological elaboration of covenant in Puritan and Separatist theology centred on the themes of election, grace, and Baptism. It is curiously ironic that covenant enactment, such as the Mayflower Compact, became historically operative but remained essentially secular, while the religious covenant became predominantly a theological concept associated particularly with Baptism—the ritual means by which a person became a participant in the covenant of grace. The essential elements in the biblical covenant—*i.e.*, that of free, voluntary acceptance of ethical obligation on the basis of and as response to past experience—has virtually always given way to covenant as fixed religious dogma that legitimizes the social structure. Covenant historically has been a means by which new communities are formed, particularly in times of rapid change, social dislocation, or political breakdown. Covenants have rarely been the actual instruments by which societies actually functioned for long, but they are extremely frequent as ideological foundations for sociopolitical legitimacy.

COVENANT IN OTHER RELIGIONS

Islām. Covenants (*mīthāq*, *'ahd*) were of great importance in the formative period of Islām (7th century AD, or 1st century AH—after the Hegira, Muḥammad's flight from Mecca to Medina). More than 700 verses of the Qur'ān, the Muslim sacred scripture, have to do with various aspects of covenant relationships. As one recent Muslim writer, Sayyid Qutb, states, Islām combines both the Old and the New Testaments (covenants) and the Last Covenant, of Islām, as well. All revelation from Adam to Muḥammad is regarded by Muslims as a unit, mediated through a series of prophets, or messengers, with whom God made a covenant: Noah, Abraham, Moses, and Jesus. Though the concept is difficult, it seems that the prophet in each case was given a revelation and a religion to which he covenanted with God to witness faithfully. This concept of a covenant of the prophets conveys the conviction of the unity of revelation as well as the unity of God in past history.

On the second level, the Muslim community itself is often regarded as being composed of those who have accepted the covenant with God. In this connection, the grace, or providence, of God in nature or creation is of great importance. In addition to this view is the repeated emphasis upon the doctrine that God alone is man's sole benefactor, and for these reasons the response of gratitude is an important element in the structure of the covenant. It is also necessary that rewards and punishments are included. These are predominantly, as in the Christian concepts, focussed upon the hereafter, paradise, and hell, though not exclusively so. The recipients of the rewards and punishments are described as those who obey or disobey Allāh's (God's) commands, which include prayer, paying the *zakāt* (head tax: an obligatory charity), belief in the messengers of Allāh, fearing God alone, and refraining from theft, adultery, murder, and false witness. They are further obligated to show kindness to parents and to strive in the cause of God with their persons and property.

Importance of the covenant in the formative period of Islām

On the historical and social level, it seems quite certain that the community of the formative period in Islām was based on covenant acts, in which persons or groups formally proclaimed their acceptance of Muḥammad's message and swore an oath of loyalty, accepting the obligations outlined above. References to the clasp of hands indicate that this was probably regarded as the formal act of commitment and acceptance by the community. In later Muslim theology, as in Christianity, the covenant idea seems to have been of comparatively little importance.

Other religions. It seems that only in the religions stemming from the biblical tradition is covenant of central importance. Though gods are often invoked as guarantors of promises sworn to in Iranian and Indic (Hindu) religious traditions, the covenant with a deity or the community as a covenant-bound one apparently was of relatively little importance, or possibly the concept has not been recovered by modern scholarship. The great importance of Mithra in early Iranian religion as god of the covenant and Mitrā-Varuṇa in Indic (Hindu) religion suggests that such concepts may have been more important than is now realized. Thus, modern scholarship has yet to indicate the importance of the covenant concept in Indo-Iranian and other religions. (G.E.Me.)

Prophecy

Prophecy, a religious phenomenon generally associated with Judaism and Christianity, is found throughout the religions of the world, both ancient and modern. In its narrower sense, the term prophet (Greek *prophētēs*, "forthteller") refers to an inspired person who believes that he has been sent by his god with a message to tell. He

is, in this sense, the mouthpiece of his god. In a broader sense, the word can refer to anybody who utters the will of a deity, often ascertained through visions, dreams, or the casting of lots; the will of the deity also might be spoken in a liturgical setting. The prophet, thus, is often associated with the priest, the shaman (a religious figure in primitive societies who functions as a healer, diviner, and possessor of psychic powers), the diviner (foreteller), and the mystic.

In a much broader sense, the term prophet has been used in connection with social and religio-political reformers and leaders.

NATURE AND SIGNIFICANCE

A primary characteristic of prophetic self-consciousness is an awareness of a call, which is regarded as the prophet's legitimization. This call is viewed as ultimately coming from a deity and by means of a dream, a vision, an audition, or through the mediation of another prophet. The Old Testament prophet Jeremiah's call was in the form of a vision, in which Yahweh (the God of Israel) told him that he had already been chosen to be a prophet before he was born (Jer. 1:5). When the call of the deity is mediated through a prophet who is the master of a prophetic group or an individual follower, such a call can be seen as a mandate. Furthermore, such mediation means that the spirit of the prophet master has been transferred simultaneously to the disciple. In the case of cult prophets, such as the prophets of the gods Baal and Yahweh in ancient Canaan, the call may be regarded as a mandate of the cult.

Prophets were often organized into guilds in which they received their training. The guilds were led by a prophet master, and their members could be distinguished from other members of their society by their garb (such as a special mantle) or by physical marks or grooming (such as baldness, a mark on the forehead, or scars of self-laceration).

The nature of prophecy is twofold: either inspired (by visions or revelatory auditions), or acquired (by learning certain techniques). In many cases both aspects are present. The goal of learning certain prophetic techniques is to reach an ecstatic state in which revelations can be received. That state might be reached through the use of music, dancing, drums, violent bodily movement, and self-laceration. The ecstatic prophet is regarded as being filled with the divine spirit, and in this state the deity speaks through him. Ecstatic oracles, therefore, are generally delivered by the prophet in the first-person singular pronoun and are spoken in a short, rhythmic style.

Prophetic ecstasy

That prophets employing ecstatic techniques have been called madmen is accounted for by descriptions of their loss of control over themselves when they are "possessed" by the deity. Prophets in ecstatic trances often have experienced sensations of corporeal transmigration (such as the 6th-century-BC Old Testment prophet Ezekiel and the 6th–7th-century-AD founder of Islām, Muḥammad). Such prophets are believed to have a predispostion for such unusual sensations.

The functions of the prophet and priest occasionally overlap, for priests sometimes fulfill a prophetic function by uttering an oracle of a deity. Such an oracle often serves as part of a liturgy, as when ministers or priests in modern Christian churches read scriptural texts that begin with the proclamation: "Thus says the Lord." The priest, in this instance, fulfills the prophetic function of the cult. Not only do the roles of the prophet and priest overlap but so do the roles of the prophet and shaman. A shaman seldom remembers the message he has delivered when possessed, whereas the prophet always remembers what has happened to him and what he "heard."

The diviner, sometimes compared with the prophet, performs the priestly art of foretelling. His art is to augur the future on the basis of hidden knowledge discerned almost anywhere, as in the constellations (astrology), the flight of birds (auspices), in the entrails of sacrificial animals (haruspicy), in hands (chiromancy), in casting lots (cleromancy), in the flames of burning sacrifices (pyromancy), and other such areas of special knowledge (see also OCCULTISM: *Divination*; SACRED OFFICES AND ORDERS: *Shamanism*).

Mystics and prophets are similar in nature in that they both claim a special intimacy with the deity. The mystic, however, strives for a union with the deity, who usurps control of his ego, whereas the prophet never loses control of his ego. On occasion mystics have delivered messages from the deity, thus acting in the role of a prophet, and have been known to use ecstatic trances to reach the divine or sacred world; *e.g.*, many Roman Catholic saints and Muslim Ṣūfīs (see below *Saint;* see also RELIGIOUS EXPERIENCE: *Mysticism*).

In the Western world, Israelite prophecy is regarded as unique, for not only did it oppose institutionalized religion but it is understood as having propagated an ethical religion emphasizing individual freedom, a religion not dependent on mechanical ritual and legalism.

Uniqueness of Israelite prophecy

The term prophecy also has been used in a strictly predictive sense, not necessarily dealing with religious themes. In this sense, *The Communist Manifesto,* by Karl Marx and Friedrich Engels, was viewed as a "prophecy" of things to come; a new approach that goes against the traditional in literature, art, politics, and other areas may—in this wider sense—be termed "prophetic."

TYPES OF PROPHECY

Types of prophecy can be classified on the basis of inspiration, behaviour, and office. Divinatory prophets include seers, oracle givers, soothsayers, and mantics (diviners), all of whom predict the future or tell the divine will in oracular statements by means of instruments, dreams, telepathy, clairvoyance, or visions received in the frenzied state of ecstasy. Predictions and foretellings, however, may also be the result of inspiration, or of common sense by the intelligent observation of situations and events, albeit interpreted from a religious point of view.

Of broad importance to the religious community is the cult prophet, or priest-prophet. Under the mandate of the cult, the priest-prophet (who may be an ordinary priest) is part of the priestly staff of a sanctuary, and his duty is to pronounce the divine oracular word at the appropriate point in a liturgy. As such, he is an "institutional" prophet. The difference between a cult prophet and a prophet in the classical sense is that the latter has always experienced a divine call, whereas the cult prophet, pronouncing the word of the deity under cultic mandate, repeats his messages at a special moment in the ritual. Because of the timeless character of cultic activity, however, every time he prophesies, his message is regarded as new.

Missionary (or apostolic) prophets are those who maintain that the religious truth revealed to them is unique to themselves alone. Such prophets acquire a following of disciples who accept that their teachings reveal the true religion. The result of this kind of prophetic action may lead to a new religion; *e.g.*, Zoroaster, Jesus, and Muḥammad. The founders of many modern religious sects also should be included in this type.

The role of prophecy in the founding of new religions

Another type of prophet is of the reformative or revolutionary kind (looking to the past and the future), closely related to the restorative or purificatory type (looking to the past as the ideal). The best examples are the Old Testament classical prophets; *e.g.*, Amos and Jeremiah. Many of these so-called literary prophets were working to reform the religion of Yahweh, attempting to free it from its Canaanite heritage and accretions. In the Arab world Muḥammad is included in this category. The social sympathy found among such prophets is rooted in their religious conscience. What may have been preached as religious reform, therefore, often took on the form of social reform. This kind of prophecy is also found in India and Africa, where prophets in modern times have arisen to restore or purify the old tribal religious forms, as well as the customs and laws that had their sources in the older precolonial religious life. Many of these movements became revolutionary not only by force of logic but also by force of social and political pressure (see above, *Eschatology*).

Though there may be several categories of prophecy according to scholars, no sharp line of demarcation differentiates among these different types. Any given prophet may be both predictive and missionary, ecstatic as well as reformative.

PROPHECY IN THE ANCIENT MIDDLE EAST AND ISRAEL

The ancient Middle East. In ancient Egypt, charismatic prophecy apparently was not commonplace, if it occurred at all, though institutional prophecy was of the greatest importance because life was regarded as depending upon what the gods said. Some ancient texts contain what has sometimes been regarded as prophetic utterances, but these more often are considered to be the product of wise men who were well acquainted with Egyptian traditions and history. Among Egyptian sages, historical events were thought to follow a pattern, which could be observed and the laws of which could be discerned. Thus, times of hardship were always thought to be followed by times of prosperity, and predictions were made accordingly.

Egyptian texts

In Egyptian mantic (divinatory) texts there are prophetic sayings, but the particular concerns of these texts are more political than religious. Some are fictitious, and many are considered to have been prophesied after the event has already taken place. The papyrus text "The Protests of the Eloquent Peasant" is considered by some authorities as a prophecy, since the peasant is forced to deliver speeches, saying: "Not shall the one be silent whom thou hast forced to speak." This compulsion to speak in the name of the divine is called by some scholars the "prophetical condition."

In a Hittite text King Mursilis II (reigned *c.* 1334–*c.* 1306 BC) mentions the presence of prophets, but there is no information about the type of prophecy. More informative are texts from Mari (Tall al-Ḥarīrī, 18th century BC) in northwest Mesopotamia, where some striking parallels to Hebrew prophecy have been discovered. The Mari prophets—believed to be inspired—spoke the word of the god Dagon just as Israelite prophets spoke the word of Yahweh.

In Mari, the two key words for prophet are *muḫḫum* (an ecstatic, a frenzied one) and *āpilum* (the one who responds). Both may be connected with the cult, but there are incidents indicating that the *muḫḫum* was not bound to the cultic setting but received his message in a direct revelation from his god. The *āpilum* usually acted within a group of fellow prophets. Many of their sayings are political in nature, but there are also oracles that deal with the king's duty to protect the poor and needy, indicating that an ethical dimension was present among the Mari prophets. The messages could also contain admonitions, threats, reproofs, accusations, and predictions of either disaster or good fortune.

The Mari texts are important in the history of prophecy because they reveal that inspired prophecy in the ancient Middle East dates back 1,000 years before Amos and Hosea (8th century BC) in Israel. From Mesopotamia there is evidence of the *maḫḫu,* the frenzied one, known in Sumerian texts as the *lú-gub-ba.* Mention also is made of some prophets who spoke to Assyrian kings, and their message is sometimes introduced with the clause: "Do not fear." Omina (omens) texts containing promises or predictions are also known. In one of the *maqlu* ("oath") texts, in which an *āšipu* priest is being sent forth by his god, the deity first asks "Whom shall I send?"

The *baru* (a divinatory or astrological priest) declared the divine will through signs and omens, and thus by some is considered to have been a prophet. Though he might possibly have had visions, he was not in actuality an ecstatic. The art of divination became very elaborate in the course of time and required a long period of training.

Zoroaster, the 7th–6th-century-BC Iranian founder of the religion that bears his name, is one of the least well-known founders of a religion because of the character of the existing textual materials and because some scholars have advocated that Zoroaster is a mythical figure. He may have been, however, an ecstatic priest-singer, or *zaotar,* who used special techniques (especially intoxication) to achieve a trance. Zoroaster found the priests and cult of his day offensive, and opposed them. He preached the coming of the kingdom of the god Ahura Mazdā (Ormazd), who is claimed to have revealed to Zoroaster the sacred writings, the Avesta. In the *Yasna* (a section of the Avesta), Zoroaster refers to himself as a Saoshyans, a saviour. Messianic prophecies of the end of the world are found in Zoroastrian literature, but these are more a literary product than actual prophetic utterance (see also ZOROASTRIANISM AND PARSIISM).

Prophets were a common phenomenon in Syria-Palestine. In an Egyptian text (11th century BC), Wen-Amon (a temple official at Karnak) was sent by the pharaoh to Gebal (Byblos) to procure timber. While there, a young noble of that city was seized by his god and in frenzy gave a message to the king of Gebal that the request of Wen-Amon should be honoured. In another instance, an Aramaic inscription from Syria records that the god Ba'al-shemain told King Zakir (8th century BC) through seers and diviners that he would save the king from his enemies. These chapters reveal the close connection between sacrificial rites and divine inspiration. In the Old Testament book of Numbers, chapters 22–24, the Mesopotamian prophet Balaam (who may have been a *maḫḫu*) from Pethor, whom the Moabite king Balak had asked to curse the invading Israelites, is mentioned. In chapter 27, verse 9, of Jeremiah, another Old Testament book, it is said that prophets, diviners, and soothsayers were in the neighbouring countries of Judah: in Edom, Moab, Ammon, Tyre, and Sidon. Since so little is known about these prophets, the question of the uniqueness of Hebrew prophecy is difficult to assess (see also MIDDLE EASTERN RELIGIONS).

Origins and development of Hebrew prophecy. The Hebrew word for prophet is *navī',* usually considered to be a loan word from Akkadian *nabū, nabā'um,* "to proclaim, mention, call, summon." Also occurring in Hebrew are *ḥoze* and *ro'e,* both meaning "seer," and *nevī'a* ("prophetess").

Though the origins of Israelite prophecy have been much discussed, the textual evidence gives no information upon which to build a reconstruction. When the Israelites settled in Canaan, they became acquainted with Canaanite forms of prophecy. The structure of the prophetic and priestly function was very much the same in Israel and Canaan. Traditionally, the Israelite seer is considered to have originated in Israel's nomadic roots, and the *navī'* is considered to have originated in Canaan, though such judgments are virtually impossible to substantiate. In early Israelite history, the seer usually appears alone, but the *navī'* appears in the context of a prophetic circle. According to I Samuel, there was no difference between the two categories in that early time; the terms *navī'* and *ro'e* seem to be synonymous. In Amos, *ḥoze* and *navī'* are used for one and the same person. In Israel, prophets were connected with the sanctuaries. Among the Temple prophets officiating in liturgies were the Levitical guilds and singers: the "sons" of Asaph, Heman, Jeduthun, who are said to "prophesy with lyres, with harps, and with cymbals" (I Chronicles). Other prophetic guilds are also mentioned. Members of these guilds generally prophesied for money or gifts and were associated with such sanctuaries as Gibeah, Samaria, Bethel, Gilgal, Jericho, Jerusalem, and Ramah. Jeremiah mentions that the chief priest of Jerusalem was the supervisor of both priests and prophets, and that these prophets had rooms in the Temple buildings. In pre-Exilic Israel (before 587/586 BC), prophetic guilds were a social group as important as the priests. Isaiah includes the *navī'* and the *qosem* ("diviner," "soothsayer") among the leaders of Israelite society. Divination in the pre-Exilic period was not considered to be foreign to Israelite religion.

Prophets connected with sanctuaries

In reconstructing the history of Israelite prophecy, the prophets Samuel, Gad, Nathan, and Elijah (11th to 9th centuries BC) have been viewed as representing a transitional stage from the so-called vulgar prophetism to the literary prophetism, which some scholars believed represented a more ethical and therefore a "higher" form of prophecy. The literary prophets also have been viewed as being antagonistic toward the cultus. Modern scholars recognized, however, that such an analysis is an oversimplification of an intricate problem. It is impossible to prove that the *nevī'im* did not emphasize ethics simply because few of their utterances are recorded. What is more, none of the so-called "transitional" prophets was a reformer or was said to have inspired reforms. Samuel was not only a prophet but also a priest, seer, and ruler ("judge") who lived at a sanctuary that was the location of a prophetic

guild and furthermore was the leader of that *navi'* guild. In the cases of Nathan and Gad there are no indications that they represented some new development in prophecy. Nathan's association with the priest Zadok, however, has led some scholars to suspect that Nathan was a Jebusite (an inhabitant of the Canaanite city of Jebus).

Elijah was a "prophet father" (or prophet master) and a prophet priest. Much of his prophetic career was directed against the Tyrian Baal cult, which had become popular in the northern kingdom (Israel) during the reign (mid-9th century BC) of King Ahab and his Tyrian queen, Jezebel. Elijah's struggle against this cult indicated a religio-political awareness, on his part, of the danger to Yahweh worship in Israel; namely, that Baal of Tyre might replace Yahweh as the main god of Israel.

Classical prophecy in Israel and Judah

The emergence of classical prophecy in Israel (the northern kingdom) and Judah (the southern kingdom) begins with Amos and Hosea (8th century BC). What is new in classical prophecy is its hostile attitude toward Canaanite influences in religion and culture, combined with an old nationalistic conception of Yahweh and his people. The reaction of these classical prophets against Canaanite influences in the worship of Yahweh is a means by which scholars distinguish Israel's classical prophets from other prophetic movements of their time. Essentially, the classical prophets wanted a renovation of the Yahweh cult, freeing it from all taint of worship of Baal and Asherah (Baal's female counterpart). Though not all aspects of the Baal-Asherah cult were completely eradicated, ideas and rituals from that cult were rethought, evaluated, and purified according to those prophets' concept of true Yahwism. Included in such ideas was the view that Yahweh was a jealous God who, according to the theology of the psalms, was greater than any other god. Yahweh had chosen Israel to be his own people and, therefore, did not wish to share his people with any other god. When the prophets condemned cultic phenomena, such condemnation reflected a rejection of certain kinds of cult and sacrifice—namely, those sacrifices and festivals not exclusively directed to Yahweh but rather to other gods. The prophets likewise rejected liturgies incorrectly performed. The classical prophets did not reject all cults, per se; rather, they wanted a cultus ritually correct, dedicated solely to Yahweh, and productive of ethical conduct. Another important concept, accepted by the classical prophets, was that of Yahweh's choice of Zion (Jerusalem) as his cult site. Thus, every cult site of the northern kingdom of Israel and all the sanctuaries and *bamot* ("high places") were roundly condemned, whether in Israel or Judah.

Amos, whose oracles against the northern kingdom of Israel have been misunderstood as reflecting a negative attitude toward cultus per se, simply did not consider the royal cult of the northern kingdom at Bethel to be a legitimate Yahweh cult. Rather, like the prophet Hosea after him, Amos considered the Bethel cult to be Canaanite.

Prophets of the ancient Middle East generally interjected their opinions and advice into the political arena of their countries, but in this regard the classical Hebrew prophets were perhaps more advanced than other prophetic movements. They interpreted the will of God within the context of their particular interpretation of Israel's history, and on the basis of this interpretation often arrived at a word of judgment. Important to that interpretation of history was the view that Israel was an apostate people—having rejected a faith once confessed—from the very earliest times, and the view that Yahweh's acts on behalf of his chosen people had been answered by their worship of other gods. In this situation, the prophets preached doom and judgment, and even the complete destruction of Israel. The source of prophetic insight into these matters is the cultic background of liturgical judgment and salvation, wherein Yahweh judged and destroyed his enemies, and in so doing created the "ideal" future. What is totally unexpected is that the prophets would go so far as to include Israel itself as among Yahweh's enemies, thus using these ideas against their own people. Usually, however, the prophets allowed some basis for hope in that a remnant would be left. The future of this remnant (Israel) lay in the reign of an ideal king (as described in Isaiah), indicating that the prophets were not antiroyalists. Though they could and did oppose individual kings, the prophets could not make a separation between Yahweh and the reign of his chosen king or dynasty. Their messianic ideology, referring to the messiah, or anointed one, is based on old royal ideology, and the ideal king is not an eschatological figure (one who appears at the end of history). In this respect, the prophets were nationalistic; they believed that the ideal kingdom would be in the promised land, and its centre would be Jerusalem.

Concepts of the remnant and of the messiah

With the Exile of the Judaeans to Babylon of 586 BC, prophecy entered a new era. The prophecies of what is called Deutero-Isaiah (Isaiah 40–45), for instance, were aimed at preserving Yahwism in Babylonia. His vision of the future went beyond the pre-Exilic concept of a remnant and extended the concept into a paradisiacal future wherein Yahweh's new creation would be a new Israel. This tone of optimism is continued in the prophetic activity (late 6th century BC) of Haggai and Zechariah, prophets who announced that Yahweh would restore the kingdom and the messianic vision would come to pass. Prerequisite to this messianic age was the rebuilding of the Temple (which was viewed as heaven on earth). When, however, the Temple had been rebuilt and long years had passed with neither the kingdom being restored nor the messianic age initiated, Israelite prophecy declined.

There is a tendency in prophetic preaching to spiritualize those aspects of religion that remain unfulfilled; herein lie the roots of eschatology, which is concerned with the last times, and apocalyptic literature, which describes the intervention of God in history to the accompaniment of dramatic, cataclysmic events. Since the predictions of the classical prophets were not fulfilled in a messianic age within history, these visions were translated into a historical apocalypse, such as Daniel. Why prophecy died out in Israel is difficult to determine, but Zechariah offers as good an answer as any in saying that the prophets "in those days" told lies. Prophets did appear, but after Malachi none gained the status of the classical prophets. Another reason may be found in Ezra's reform of the cult in the 5th century BC, in which Yahwism was so firmly established that there was no longer any need for the old polemics against Canaanite religion.

Prophecy and apocalyptic literature. With the advent of post-Exilic Judaism (Ezra and after), including its emphasis on law and cult, there was not much room left for prophecy. The prophetic heritage was channelled through the teaching of their words. What remained of prophetic activity was expressed in various literary works that claimed esoteric knowledge of the divine purpose. The apocalyptic writers saw themselves as taking over and carrying on the prophetic task, but they went beyond the prophets in their use of old mythological motifs. The events they described had usually occurred long ago, but their recounting of these events was for the purpose of hinting and even predicting the events of the future. There was a far greater emphasis upon predictive speculation about the future than on the prophetic analysis and insight into history. The apocalyptic authors wrote pseudonymously, using the names of ancient worthies (such as Adam, Enoch, Abraham, Daniel, and Ezra). The literature is predominantly prose, but that of the classical prophets was predominantly poetry. Apocalyptic language is lavish in its use of fantastic imagery, frequently using riddles and numerical speculations. In apocalyptic literature angelology came into full blossom, with accounts of fallen angels (fallen stars) caught up in the forces opposed to God, frequently pictured in the old mythological motif of the struggle between darkness and light. Wild beasts symbolized peoples and nations, and there were esoteric calculations and speculations about the different eras through which history was passing as the world approached the eschaton (the consummation of history).

Reinterpretation of the prophetic heritage

Dominant in apocalyptic literature is the theme of God's sovereignty and ultimate rule over all the universe. The message of the apocalyptic writers is one of both warning of the doom to come at the end of history, and hope in the new age beyond history under the rule of God, when the righteous will be vindicated (see above, *Eschatology*).

Prophecy and prophetic religion in postbiblical Judaism. Though prophecy did not cease functioning in early Judaism, rabbinical Judaism—that influenced by rabbis, scholars, and commentators of the Bible—sought to limit it by advocating the pre-Exilic era as the classical time of prophecy. Prophecy was not suppressed, but it came to be encircled by the law (Torah) in that all prophecy had to be in harmony with Torah, which was the definitive revelation of God's will. Thus, rabbinical Judaism gave prophecy its place of importance, but only as a phenomenon of the past. Such a theological stricture could not restrain the charismatic, eschatologically oriented patriots who arose during the time of Roman hegemony (mid-1st century BC–4th century AD). One rabbi, Akiba ben Joseph, joined with a messianic pretender, Bar Kokhba (originally Simeon ben Koziba) in a revolt (132–135) and functioned as a prophet within that movement.

Eschatologically oriented prophets

Some prophets are known from the period of Hellenistic Judaism. I Maccabees, chapter 14, relates that Simon Maccabeus, who finally secured political independence for Judaea in 141/140 BC, was chosen as "leader and high priest forever, until a trustworthy prophet should arise." The same notion of a prophet soon to appear is expressed in chapter 1 of I Maccabees. The Hasmonean (Maccabean) prince John Hyrcanus (reigned 135/134–104 BC) was regarded as fulfilling these expectations and was called a prophet by the 1st-century AD Jewish historian Josephus (*Jewish War*). Josephus also mentions some Zealots (Jewish revolutionaries) as prophets and also one Jesus, son of Ananias, who in AD 62 predicted the destruction of the Temple and the defeat of the Jews. Josephus also mentions the seer Simon, a prophet leader (*Antiquities*), and Menahem, who prophesied in the 1st century BC. Among the followers of Judas Maccabeus, the leader of the 2nd-century-BC revolt, there apparently were persons who divined knowledge of the future. These and other notations indicate that seers and prophets played an important role in the intertestamental and postbiblical periods.

Jewish theology in Alexandria (Egypt) took up early rabbinical ideas and postulated that the will of God was to be discerned in the Torah and affirmed that the interpretation of law succeeded both the prophetic office and the role of sages. The law was thus considered to be superior to prophetic teaching. The Jewish philosopher Philo of Alexandria (*c.* 30 BC–after AD 40) affirmed that the Jews are a people of prophets. He also asserted that when a prophet has reached the fourth and final stage of ecstasy he is ready to become an instrument of divine power. Though Philo was influenced by Hellenistic concepts of prophecy, his basic foundation was still the Old Testament. Later rabbis believed that prophecy, though it was a gift from the world beyond, still required some knowledge. In rabbinic discussions of the nature of truth, it was generally held that reason alone was necessary but insufficient; prophecy could supply what was missing.

Superiority of law in relation to prophecy

The medieval Jewish philosopher Maimonides understood prophecy as an emanation from God to the intellect of man. Thus, prophecy could not be acquired by human effort. The divine gift of prophecy was bestowed upon those with both mental and moral perfection, combined with the presence of superior imagination. Opponents of this view advocated that Maimonides' concept of prophecy was not Jewish because Jewish prophecy always showed itself to be miraculous (see also JUDAISM).

PROPHECY IN CHRISTIANITY

Divination and prophecy in the Hellenistic world. The problem of false prophets that occurred in Old Testament times also occurred in the early Christian communities. Prophets and diviners were widespread throughout the Hellenistic world. The Greek *prophētēs* was not only a forthteller but also an interpreter of divine messages. In addition, there were mantics (from the Greek *mantis*)—*i.e.*, visionary seers—whose visions were interpreted by prophets, soothsayers, diviners of all kinds, and especially astrologers. The impetus for much of this activity came from Babylonia. The influx of new religions from the East brought a profusion of astrologers and prophets. Many schools of astrology were founded throughout the Hellenistic world, and old schools of philosophy became very much occupied with astrology.

New Testament and early Christianity. Prophecy in the New Testament is seen as both a continuation of Old Testament prophecy as well as its fulfillment. For New Testament authors, the correct interpretation of Old Testament prophecy is that it speaks *in toto* of Christ. To prove their point, they often cite passages of Old Testament prophecy that are then elucidated as the words of God about Christ. New Testament writers follow Jesus himself in this matter, and Jesus is taken to be the prophet that was promised in Deuteronomy (see John 1:45, *cf.* 5:39, 6:14; Acts 3:22 *ff.*). Jesus regarded himself as a prophet, and so did some of his contemporaries. One special aspect of the prophetic image, however, is missing in Jesus: he was not an ecstatic, although supernatural revelations are found in connection with him; *e.g.*, the transfiguration of Jesus as witnessed by some of his Apostles on Mt. Tabor. In these New Testament descriptions of the transfiguration, Jesus is proclaimed to be the Son of God in words borrowed directly from Old Testament enthronement ritual. As a prophet, Jesus predicted his own death, his return as the Son of man at the end of the world, and the destruction of the Jerusalem Temple. At many points, Jesus is compared with and interpreted by the classical prophets in New Testament writings: his death—seen as the martyrdom of a prophet, his sufferings, and even his identity.

Though the New Testament describes Jesus as a prophet, he is at the same time believed to be more than a prophet: he is the expected Messiah (Greek *christos*, "anointed one"), predicted by prophets of old, who should reign as the Son of David and the Son of God. The royal ideology of the Old Testament was most important to early Christianity, for herein lay the seeds of its doctrines of Christ (see above, *Eschatology*).

Several prophets are mentioned in the New Testament. One, Zechariah, is said to have perished "between the altar and the sanctuary" (Luke). Reference to his death is included by the Gospel writers because he was the last prophet before Jesus to have been killed by the Jews. Zechariah, the father of John the Baptist, uttered the Benedictus ("Blessed," the initial Latin word of the prophetic song) under the inspiration of the spirit. His wife, Elizabeth, also was described as being inspired by the spirit.

Others are Simeon, the prophetess Anna, and John the Baptist. These prophets are conceived by the New Testament writers as the termination of Old Testament prophecy, a concept also expressed by Jesus with reference to John the Baptist.

New Testament prophetic figures

The New Testament mentions several prophetic figures in the early church. Among them are Agabus of Jerusalem; Judas Barsabbas and Silas, who also were elders of the Jerusalem Church; the four prophesying daughters of Philip the evangelist; and John, the author of Revelation. The term prophet is used with reference to an office in the early church along with evangelists and teachers, and the recipient of the letter bearing his name, Timothy, is called both a minister and a prophet. The prophet's role in the early church was to reveal divine mysteries and God's plan of salvation. Paul instructed his followers in the correct use of prophecy, and evaluated it as more beneficial to the life of congregations than ecstatic glossolalia (speaking in tongues). He considered prophecy to be the greatest spiritual gift from God, and in his view a prophet therefore ranks ahead of evangelists and teachers. With all this prophetic activity, the problem of false prophecy was crucial, and warnings against it abound in the New Testament. The most dangerous of the false prophets is predicted in the book of Revelation to John as yet to come. Many of these prophets, viewed as magicians and exorcists, are condemned for inducing chaos and for leading people astray. Therefore all prophetic activity had to be examined.

In the period immediately after the Apostles, prophets continued to play an important leadership role in the church, sometimes being called high priests. They were the only ones permitted to speak freely in the liturgy because of their inspiration by the Holy Spirit. Gradually, however, the liturgy became more and more fixed, and

less freedom and innovation was permitted; this change, combined with the threat of false prophecy, eliminated these charismatic personalities. Among the heretical sects
Montanism that advocated a return to prophetic activity, Montanism (2nd century), led by the prophet Montanus, advocated that the spirit of truth had come through Montanus. The freedom of doctrinal innovation that Montanus advocated could well have led to doctrinal anarchy, and the result of the struggle against this heresy was the suppression of charismatic prophecy, wherein ecstatic inspiration came to be viewed by the church as demonic.

Another prophet who created a problem in the early church was Mani—the 3rd-century founder of a dualistic religion that was to bear his name (Manichaeism)—who considered himself to be the final messenger of God, after whom there was to be no other.

Prophetic and millenarian movements in later Christianity. In Western medieval church doctrines and rituals, active prophecy had no place. Prophetic activity was carried on, however, through holy orders. Mystically oriented holy men would sometimes appear as prophets with a special message, and even ecstatics found their places within the monasteries. In Eastern Christianity, monastic life stressed training in mystical experience.

Throughout Christian history there have been millenarian movements, usually led by prophetic-type personalities and based on the New Testament belief in Christ's return. Their basic doctrine is chiliasm (from Greek *chilioi,* "thousand"), which affirms that Christ will come to earth in a visible form and set up a theocratic kingdom over all the world and thus usher in the millennium, or the 1,000-year reign of Christ and his elect.

The early and medieval church hierarchy generally opposed chiliasm because such movements often became associated with nationalistic aspirations. Though the key leaders of the Protestant Reformation opposed chiliasm, and therefore minimized its effects upon the emergent denominations (*e.g.,* Lutheran, Calvinist, and Anglican), chiliasm did influence Anabaptist circles (radical reformation groups), and through them chiliastic ideas influenced Protestant Reformed theology and have appeared in reform movements, such as Pietism in Lutheran churches, and various revivalistic movements.

PROPHECY IN ISLĀM

The centrality of prophecy in Islām. Pre-Islāmic prophecy in Arabia was no different in character from other Semitic prophecy. Pre-Islāmic terms for prophet are *ʿarrāf* and *kāhin* ("seer," cognate to Hebrew *kohen,*
The role of the *kāhin* "priest"). The *kāhin* could often be a priest, and as a diviner he was an ecstatic. The *kāhin* was considered to be possessed by a *jinnī* ("spirit"), by means of whose power miracles could be performed. Also, poets were considered to be possessed by a *jinnī* through whose inspiration they composed their verses. The importance of the seers and diviners was noted in all aspects of life. Any problem might be submitted to such men, and their oracular answers were given with divine authority. It is not surprising, therefore, to find that a *kāhin* often became a sheikh, a temporal leader, and there were instances in which the position of *kāhin* was hereditary.

It was against this background that the founder of Islām, Muḥammad, appeared. During his early career in Mecca (in Arabia) he was considered by his tribesmen, the Quraysh, to be only another *jinnī*-possessed *kāhin.* His utterances during this time were delivered in the same rhymed style as that used by other Arab prophets and were mostly the products of ecstatic trances. At about 40 years of age Muḥammad experienced the promptings of the one god, Allāh, and retreated into the solitude of the mountains. These retreats served psychologically as preparations for his later revelations. The central religious problem of Muḥammad was the fact that Jews had their sacred scriptures in Hebrew, and Christians had theirs in Greek, but there was no written divine knowledge in Arabic. Muḥammad's preoccupation with this concern, along with a sense of the coming Day of Judgment, became the seeds of his new religion. Contemplation had matured Muḥammad, and biographers point out that, as one may conclude from the Qur'ān, Muḥammad received the divine call in a vision. His ecstatic revelations were in the form of auditions, usually involving the angel Gabriel reading the divine message from a book. The illiterate Muḥammad had his wife Khadījah, who was 15 years his senior, record them, and they are preserved in the Qur'ān. Because this is believed to be a verbatim copy of the Heavenly Book, literally the words of Allāh himself, it cannot be questioned.

Muḥammad considered himself to be more than a mere prophet (*nābī*); he thought of himself as the messenger (*rasūl*) of Allāh, the final messenger in a long chain that had begun with Noah and run through Jesus. As Allāh's *rasūl,* Muḥammad saw his first mission to be that of warning the Arab peoples of the impending doomsday. No doubt Muḥammad was influenced by the Judeo-Christian tradition in his concept of the Day of Judgment, as well as in his concept of himself as a prophet. Muḥammad, who had felt at one time that Arabs were religiously inferior to Jews and Christians, became the medium of revelations that created Islām and raised the Arabs in Muḥammad's own evaluation to a status equal with that of the other two religions.

After AD 622, when Muḥammad left Mecca and found refuge in Medina, ecstatic revelations began to play a secondary role in his prophecy—due to his political concerns—and not only does the rhymed prose of his message give way to more conventional prose but the content is more obviously the product of reasoned reflection on all aspects of life.

The Qur'ānic doctrines of prophecy. An official Islāmic view, and also that of Muḥammad himself, was that
The final Prophet Muḥammad was the final Prophet. The Qur'ān mentions those men who are considered to have imparted divine knowledge: Adam, Noah, Abraham, Isaac, Jacob, Moses, David, and Jesus. None of these revealed Allāh's message in full, since they were sent only to one nation. Muḥammad, on the other hand, was sent to all nations and also to the *jinn.* The messages of the prophets before Muḥammad were believed to have been either forgotten or distorted, but Islām claims that the Qur'ān both corrects and confirms the sayings of the earlier prophets; Muḥammad is the "seal of the prophets"; *i.e.,* the end of prophecy. All prophecy before Muḥammad is incomplete and points to the coming of the final revelation.

The prophetic activity of Muḥammad serves as the foundation of Islām and Muslim society. The incomparable revelations of Muḥammad are believed to have brought true monotheism into the world, to which nothing can be added or taken away. Thus, there is no more need of prophets or revelations.

Later theological and philosophical doctrines. After the death of Muḥammad, the expansion of Islām brought it into contact with the world at large, and a Muslim culture (involving science, philosophy, and literature) emerged, partially as a result of the Muslim acquisition of Byzantine culture. Christians and Jews became advisers and officials in Muslim courts. Christian philosophers introduced Muslim students to the works of the 4th-century BC Greek philosopher Aristotle and to Neoplatonism (a philosophical system concerning the complex levels of reality), to theories about the nature of man, to theology, to the nature of existence, and to cosmology. Philosophical discussions about God, however, leave little or no room
Displacement of prophets for prophets, and the savant displaced the prophet as the one proclaiming the will of God. As religious leaders, the savants were the keepers of *sunnah* (the life and habits of the prophet) and *ḥadīth* (traditions about Muḥammad's utterances and actions), which are supplements to the Qur'ān. Study of *ḥadīth* and *sunnah* contributed to the beginning of scholarly and scholastic activities in Islām, from which study emerged the Muslim system of duties and obligations (*fiqh*). Muslim theology began in the formulation of the doctrine of the general consensus (*ijmāʿ*), which was used to determine what was genuine *sunnah.* None ventured to question that Allāh was the only God, that Muḥammad was his prophetic messenger, or that the Qur'ān was Allāh's word; to have done so would have been tantamount to admitting that one was not a Muslim.

Scholastic philosophy was first introduced openly into Muslim theology by al-Ash'arī (10th century) who was the first to give Islām a systematic exposition. Another theologian, Ibn Sīnā (Avicenna), considered prophecy still to be a fundamental aspect of Islām, but for him, a prophet was not the spirit-possessed spokesman of God but rather an intelligent, intuitive man whose insight results in a place of leadership in society. Another philosopher, Ibn Rushd (Averroës), denied the belief that man's knowledge could ever be the same as God's knowledge; he also denied doctrines of predestination and corporeal resurrection, both of which were aspects of Muḥammad's message.

Prophetic figures after Muḥammad. The fact that Muḥammad was considered to be the final prophet did not end prophecy in Islām. After Muḥammad's death, several seers proclaimed themselves his successors. Muḥammad had designated no one to succeed himself, and left no sons. Abū Bakr, the father of Muḥammad's wife 'A'ishah, was chosen caliph (Arabic *khalīfah,* "substitute, deputy"), but this did not discourage others from claiming that they were called of Allāh and thus trying to lead their own tribes as Muḥammad had led his. Such movements were crushed by force, which contributed to the rapid expansion of Islām.

The *mahdī*

Some prophets claimed that they were long-awaited saviour-deliverers (*mahdī,* "restorer of the faith") and even gained some following beyond their own local tribes. Muḥammad Aḥmad ibn as-Sayyid 'Abd Allāh of the Sudan preached a holy war against Egypt (1881) and fought and defeated the British governor-general C.G. Gordon at Khartoum in 1885. In India (Punjab), Mirza Ghulan Aḥmad claimed that he had received the spirit of Jesus and that he was a prophet-messiah. He recorded his revelations from Allāh in a book. Considering himself to be the Christ to his generation, he set out to reform Islām by liberalizing strict orthodoxy, yet avoiding the extremes of the pro-Western movements of his time. He gained a large following among middle-class Muslims, but was soon disowned by orthodox Islām. His sect (Ahmadiyah), though small in numbers, has through its missionary activities spread over much of the world. Its sociopolitical stance is similar to that of the Black Muslims of the United States (see also ISLĀM).

PROPHECY IN OTHER RELIGIONS

Prophetic movements and figures in the Eastern religions. Buddhist literature contains predictions of a certain Buddha Maitreya, who will come as a kind of saviour-messiah to inaugurate a paradisaical age on earth. Gautama the Buddha himself, the 6th-century-BC founder of Buddhism, mentioned this prediction. Among the Hindus, the *Purāṇa* literature ("old history") contains prophetic passages, but these are to be understood as predictions after the event has occurred. Hindu religion has had many prophetic reformers, and the tribes of India, in their struggle for freedom, have produced prophets who combined the ideas of religious freedom with the hope of political and social freedom. The Oraons, a tribe in Chota Nāgpur, saw several prophets (*bhagats*) appear around the turn of the 20th century. Their intent was to free their people from foreign culture and political rule, returning to the older Hindu culture and religion. Such efforts often led to armed rebellion and ended in disaster.

In ancient China, divination was commonplace. One Confucian book involving divination, the "Classic of Changes," may have been connected with pre-Han Confucianism (before the 3rd century BC). Classical Confucian religion, however, emphasized the importance of rational process over inspiration and divination. Autocratic governments eliminated any such revolutionary, prophet-led movements as occurred in India, and any prophecy against the establishment was regarded as heretical. Inspired prophecy found little place in the official state religion. This situation did not rule out prophecy in folk religion, in which prophets appeared and promised their followers the good life in this world and in the next. In modern times, some of these movements became religio-political movements, as when Hung Hsiu-Ch'üan, an ecstatic epileptic noble of the middle 19th century, started a movement called the Taiping ("Great Peace"), a sect claiming that it was establishing the correct political order anew. Hung's movement—perhaps under the impact of Protestant missions—was quite austere, and it opposed magic, idols, and belief in spirits. He considered the New Testament to be authoritative for his new sect, and its rapid growth—aided by connections with other revolutionary movements—soon resulted in a genuine danger to the Manchu ruler of China. The Taiping Rebellion was crushed by Gordon in 1864.

Folk religion prophets

Diviners and shamans (male and female) are well represented in old Japanese Shintō. Japanese shamanism, which was closely related to Korean shamanism, often played a role in political disturbances and still does. Among old Japanese Buddhist sects is that founded by Nichiren (13th century AD), a prophetic enthusiast, religious revivalist, and zealous nationalist who taught that the Japanese people were the chosen people of God. In the Shintō revival movements of the 18th and 19th centuries, inspired persons with eschatological concepts founded movements that became messianic in character, and drew many of their followers from among the farmers, many of whom had practiced a Buddhist folk piety.

Prophetic movements and figures in the religions of nonliterate cultures. In many nonliterate cultures, especially those of Africa, shamans, seers, and prophets are quite common. The same distinction between technical divination and charismatic prophecy is to be found in these cultures as in the ancient Middle East. When it is possible to trace the history of prophetic activity in Africa, scholars usually find that it arises in times of confrontations with foreign cultures and with the advent of new religions. A sharp distinction between the diviner and the prophet cannot always be maintained, for diviners sometimes appear as prophets. A diviner may hear the voice of a god or spirit in his dreams and visions (in Zulu he is called a "dreamhouse") and receive a message. Some prophets, avowing a call, deny any training in prophecy. There are many parallels with the "rebel" prophets of India. Ecstatic prophets have played an important role not only in chiliastic and messianic movements but also in those movements opposing imperialism and European colonization of Africa. Their goal was and is a return to the old African culture and religion. Eschatological motifs have often been used in the prophetic preaching of tribal and national movements aspiring for freedom. Many of these prophets took up Christian ideas. Nxele, a 19th-century prophet of the South African Xhosas, preached the return of the dead on a certain day, and his successor, Mlandsheni, claimed to be the reincarnation of Nxele. He and others like him were healers and miracle workers.

Some of the prophetic founders of reform movements, which often were more political than religious, became messianic figures. Other prophets started out as Christian converts but came to a strong awareness that God had destined them to separate from their churches and lead syncretistic movements (fusions of various sources), all of which incorporate aspects of old African religion and, often, allow polygamy. In all these movements, syncretistic or not, there are also many prophetesses.

Prophets also have been found among American Indians. In 1675 a medicine man, Popé, arose as a prophetic leader among the Pueblo Indians. He preached the end of Spanish tyranny and a restoration of Indian sovereignty. At the height of the movement, several massacres took place, along with the burning of various church buildings.

(G.W.A.)

Miracle

Miracles are extraordinary and astonishing happenings that are attributed to the presence and action of an ultimate or divine power. This section treats the nature, functions, and sources of miracles; it then attempts to discover the place of miracles in the religions of the world and the variety of interpretations given to them. It considers miracles mainly as seen, experienced, and interpreted in the religious context, irrespective of the scientific or philosophical judgment passed on them from the outside.

NATURE AND SIGNIFICANCE

Etymology and definition

A miracle is generally defined, according to the etymology of the word—it comes from the Greek *thaumasion* and the Latin *miraculum*—as that which causes wonder and astonishment, being extraordinary in itself and amazing or inexplicable by normal standards. Because that which is normal and usual is also considered as natural, miracles have occasionally been defined as supernatural events, but this definition presupposes a very specific conception of nature and natural laws and cannot, therefore, be generally applied. The significance of a miraculous event is frequently held to reside not in the event as such but in the reality to which it points (*e.g.*, the presence or activity of a divine power); thus, a miracle is also called a sign—from the Greek *sēmeion* (biblical Hebrew *ot*)—signifying and indicating something beyond itself. Extraordinary and astonishing occurrences become specifically religious phenomena when they express, reveal, or signify a religious reality, however defined.

Belief in miraculous happenings is a feature of practically all religions, and the incidence of miracles (*i.e.*, of belief in and reports regarding miracles) is universal, though their functions, nature, purpose, and explanations vary with the social and cultural—including theological and philosophical—context in which they appear. However inexplicable, all miracles have an explanation in the sense that they are accounted for in terms of the religious and cultural system that supports them and that, in turn, they are meant to support. Without such an accompanying—explicit or implicit—theory (*e.g.*, the presence, activity, and intervention of such realities as gods, spirits, or magical powers), there would be no miracles in the aforementioned sense but only unexplained phenomena.

TYPES AND FUNCTIONS OF MIRACLES

There is no general rule determining the types of occurrences that can be classified as miracles; they vary according to the cultural matrix of beliefs and assumptions. The mythological accounts of the origins of the gods and their activities in the primeval past, as well as accounts of the activities of other primeval beings, such as first ancestors and culture heroes, should, perhaps, not be classed as miracles, and the term is better reserved for outer, objective events—as distinct from such phenomena as inner experiences and visions—that can be regarded as divine interventions or as manifestations of divine or supernatural powers. In many cultures, primitive as well as some that were more highly developed, such as the ancient classical and Oriental civilizations, the operation of extraordinary forces was taken for granted and was integrated into the total world picture and into the procedures and the modes of action—*e.g.*, magic, oracles, divination, and shamanism—of ordinary life. There were certain kinds of divine or spirit action and of cosmic operation that were considered to be a part of the normal order of things, even though it was generally admitted that priests and shamans would frequently resort to deception in their diverse activities, which included such manifestations as prophecy, oracles, healing, magic, and judgment by ordeal.

Purposes of miracles

Revelation and signification. The purpose of a miracle may be in the direct and immediate result of the event—*e.g.*, deliverance from imminent danger (thus, the passage of the children of Israel through the Red Sea in the Old Testament book of Exodus, chapter 14), cure of illness, or provision of plenty to the needy. Nevertheless, the ultimate purpose frequently is the demonstration of the power of the god or of the saint, the "man of God" through whom the god works, to whom the miracle is attributed. Thus, the crossing of the Red Sea by the Israelites is described not solely in terms of salvation from great danger but as a revelation of the saving presence of God and of the consequent obligation to serve and obey him; according to the account in Exodus: "and Israel saw the great work which the Lord did against the Egyptians, and the people feared the Lord; and they believed in the Lord and in his servant Moses." The purpose of a miraculous occurrence is thus often to reveal a divine reality or numinous dimension. The occurrence may be an event concerned with natural needs or situations, such as illness, hunger, or distress, or a specifically religious event that effects some form of salvation or revelation, such as the theophany on Mt. Sinai in which God gave to Moses the Ten Commandments, the Resurrection of Jesus Christ, or the revelation of the Qur'ān to Muḥammad. Even in these specifically religious events, the miraculous element is not necessarily of the essence but occurs as merely an accompanying circumstance designed to arrest the attention and to impress on everyone the unique character and significance of the occasion. Thus, theoretically at least, the theophany at Mt. Sinai could have taken place without thunder and lightning; Jesus need not have been born of a virgin; Muḥammad need not have made his miraculous journey to heaven. In actual fact, however, the very nature and quality of a religious event attracts miraculous elements, elaborations, and embellishments; and thus, for example, the founders of almost all religions are at the centre of great miracle cycles, and miracles occur as a rule in connection with persons and objects of religious significance, such as saints, sacraments, relics, holy images, and the like.

Authentication. In practice it is difficult to distinguish the revelatory or signifying miracles from miracles of authentication—*i.e.*, miraculous happenings that serve: (1) as credentials for claimants to religious authority in the form of leadership (*e.g.*, in Exodus, chapter 4, Moses convinces the Israelites of the authenticity of his mission by miraculous performances) or prophecy (*e.g.*, in Deuteronomy, chapter 18, it is said that a prophet is disqualified if the sign that he has predicted does not come to pass); (2) as the demonstration of the superior power of a particular god (*e.g.*, in Exodus, chapter 7, Aaron's staff swallowed up the staffs of the Egyptian magicians, which showed the superiority of the God of the Israelites); (3) as proof of the sanctity of a holy man, a holy site, or a holy object; or (4) more generally as evidence of the truth of a particular religion.

SOURCES OF MIRACLES

Spiritual sources. The source of miracles is always a divine, spiritual, supernatural, sacred, or numinous power that may be conceived in personal form (*e.g.*, God, gods, spirits) or impersonal form (*e.g.*, mana or magic). The sacred may manifest itself in natural phenomena, such as thunderstorms or earthquakes, that evoke appropriate feelings of awe, but these are not usually considered miracles unless attended by special circumstances—*e.g.*, being predicted by a "man of God" or coinciding with an event of religious significance. As reported in the Gospel According to Matthew, chapter 27, at the moment of Jesus' death on the cross, "the curtain of the temple was torn in two, from top to bottom; and the earth shook, and the rocks were split; the tombs also were opened, and many bodies of the saints who had fallen asleep were raised, and coming out of the tombs after his resurrection they went into the holy city and appeared to many." The belief that thunder and lightning are manifestations of divine powers is very common, and many deities have been interpreted as personifying them or at least as being symbolized by them. Even in the Old Testament, thunderstorms and lightnings appear as manifestations or messengers of God. In this respect, the account of the theophany granted to the prophet Elijah in I Kings, chapter 19, marks a milestone in the history of religions, for "behold, the Lord passed by, and a great and strong wind rent the mountains, and broke in pieces the rocks before the Lord, but the Lord was not in the wind; and after the wind an earthquake, but the Lord was not in the earthquake; and after the earthquake a fire, but the Lord was not in the fire; and after the fire a still small voice" in which Elijah heard God.

Natural phenomena accompanied by special circumstances

In most cases theophanies and divine manifestations occur for a specific purpose: giving laws (*e.g.*, Moses and the theophany at Mt. Sinai; events in the lives of Numa Pompilius of Rome, Minos of Crete, and Lycurgus of Sparta, the ancient lawgivers in classical legend); saving interventions (*e.g.*, the voices resounding from the temple of Athena Pronaea in Delphi that caused the Persians to retreat); and the founding of cults (*e.g.*, the appearances of Mary, the mother of Jesus, at Lourdes, France, and

Fatima, Portugal). Gods would appear to their devotees in visions and dreams, but these experiences should, perhaps, not be treated under the same general heading with other miracles. Immediate divine action was often perceived in omens preceding important undertakings, in apparently natural phenomena occurring providentially at critical moments or in miraculous—*i.e.,* sudden and seemingly impossible—cures. In most cases, however, such divine interventions took place through some form of mediation, human or inanimate.

Human and inanimate sources. Man can be the object of miracles, as when his disease is miraculously healed, or their subject, as when he performs miracles, such as healing others, in the name of whatever power is moving him. The two aspects cannot always be strictly distinguished, as is seen in the case of saints whose bodies are immune from corruption after death or founders of religions whose birth is attended by supernatural manifestations. Generally speaking, however, it is the role of holy personages—and of their tombs and relics—as sources of miracles that are of importance in the history of religions and more especially in the history of popular cults.

Subjects of legends

Founders of religions. The attitudes of the founders of the great religions toward miracles vary considerably, but all have become the subject of legends of the most fantastic kind in popular belief, and much of this legendary material has been subsequently canonized in scripture and tradition.

Holy persons. Much closer to the lives and devotion of ordinary folk than the superhuman figures of the founders are the saints, monks, ascetics, and diverse kinds of holy men and women. The attitude toward saints and their miracles is very much the same on the popular levels of all religions, although the theoretical interpretations on the more theological level vary considerably. In Far Eastern religions it is often difficult to distinguish between saints and hero gods, because great men of renowned virtue can be deified and venerated and even receive officially approved state cults. Miracles occur as a matter of course at their tombs and relics. In Muslim as well as in Christian belief, the occurrence of miracles is part of the requirements for official recognition of sainthood and is interpreted as a special intervention by God, who thereby manifests his esteem for the saint or, more essentially, his salvific presence as realized concretely in the life and virtues of the saint. In Indian—Hindu and Buddhist—belief, miraculous powers are the "natural" result of ascetic practice and spiritual realization and can thus be considered as an almost natural manifestation of magical or spiritual causes.

Relics, images, and amulets

Sacred objects. Because the life span even of saints is limited, most of the miracles attributed to them occur through their inanimate remains at their tombs or through their relics. These relics may be parts of their bodies—often deliberately dismembered for wider distribution, so that a bone may be in one place, a hair in another, and the heart someplace else—or objects or parts of objects associated with their lives (*e.g.,* the shroud of Christ or fragments of the True Cross).

Not all miracle-working objects of veneration are relics. Statues and icons can work miracles, and in many Christian countries images and icons of the Virgin Mary are especially famed for their miraculous virtues. In the Christian Middle Ages the veneration of the sacrament of the Eucharist brought about a proliferation of miracles. Here, as in the case of images, a distinction can be made between the magical character of folk beliefs and the diverse theological doctrines concerning these religious objects; only rarely have religious authorities opposed the cult of saints, images, and relics and the concomitant belief in miracles—an exception is classical Protestantism, which in the 16th century rejected such cults.

Although they are not strictly sources of miracles, talismans and amulets—*i.e.,* objects believed to possess magical virtues such as good luck or protection of the bearer or owner from all kinds of danger—should be mentioned in this connection. They are found in diverse forms and sizes and in all kinds of material.

Sacred places. Miracles are often connected with special sacred places. Normally these are natural shrines, such as sacred groves, or temples and sanctuaries in which a god or spirit lives or has manifested himself or in which his statue, symbol, holy objects, or relics are enshrined. Holy places, such as Mecca and the Kaʿbah in Islām or the Buddhist stupas, are centres of pilgrimages and veneration because of their religious significance and the religious values that they symbolize and not necessarily because miracles are wrought there; yet, popular devotion associates miracles with many of these holy sites.

MIRACLES IN THE RELIGIONS OF THE WORLD

It has already been suggested that the mythologies of primitive and ancient religions should not be designated miraculous insofar as they deal with mythical origins and ages; frequently they attempt to explain how certain regularities and what is now considered the normal course of things have come into being. The crucial distinction lies between religion on the popular primitive level and the more highly developed forms of religious belief. The tendency of the former is to relate to a concrete, magical presence of the sacred and to envisage the possibility of using this presence for the achievement of such desired ends as healing, blessing, or success in an undertaking. The higher forms of religion—though recognizing miracles or even demanding dogmatic affirmation of belief in them—exhibit a far more differentiated and complex attitude.

Hellenistic religion

Hellenistic religion presents one of the best examples of a civilization in which miracles play a major part. The intervention of the gods in the affairs of the Homeric heroes takes place in a cosmos in which the divine and human spheres still interact. Later Hellenistic syncretism conceived of the sublunar world as a distinct sphere, though higher powers could miraculously irrupt into it. Miraculous cures (*e.g.,* at the sanctuary of Asclepius at Epidaurus), divine manifestations of various kinds (*e.g.,* voices, dreams, and theophanies), and even virgin births and resurrections were widely reported.

Religions of the East. In the great religions of the East the belief in miracles is closely connected with the theory that ascetic practices and the knowledge of mystical formulas, such as the Sanskrit *mantras,* can give the practitioner unlimited magical powers.

Religions of India. India has become the classic land of wonders not because of the accounts of fantastic actions of divine beings or semidivine heroes and avatars (incarnations of Hindu gods) related in Indian mythology but because both popular religion and philosophical theory set no bounds to the magical powers that can be attained by great ascetics and yogis (adherents of Yoga, the Hindu philosophy teaching the suppression of all activity of mind, body, and will in order that the self may realize its distinction from them and attain liberation). Even if these magical powers are considered insignificant in higher religion and spiritually negligible, their reality is never doubted. The *Upaniṣad* and the *Brāhmaṇa*—ancient Sanskrit writings of the Vedic period—may consider the heights of religious insight and mystical experience as man's supreme aim, but neither the later classical sources nor contemporary Hindu belief ever question the miraculous powers of a holy man. The same attitude is shared by the other religions of Indian origin: Jainism and Buddhism.

The Buddha

The Buddha himself refused to spread his teaching by impressing his audience with miracles. According to the Aṅguttara Nikāya, one of the collections of the Buddha's sayings, there are three kinds of miracles—the miracle of magic, the miracle of thought reading, and the miracle of instruction—and of these the last is the most wonderful and excellent, whereas the other two are not much better than a conjuror's tricks. Yet the same text also describes what is implied by the miracle of magic: "there is one who, . . . having been one becomes many, . . . appears and vanishes, unhindered he goes through walls. . . . He dives in and out of the earth as if it were water. Without sinking he walks on water as if on earth. Seated cross-legged he travels through the sky like a winged bird. With his hand he touches and strokes the sun and the moon. . . ." The same text also asserts that not only was Gautama endowed

with these powers but so also were hundreds of monks of his order.

Religions of China. In China, although Confucianism in the strict sense has little room for miraculous elements, Taoism has produced a rich crop of thaumaturgy and magic on all levels of folk religion. No doubt the teaching of the Tao (literally, the Way) can be interpreted in terms of a sublime moral and perhaps even mystical doctrine. In actual fact it was one of the main sources of Chinese magic in all its forms, including the quest for the elixir of life. Religious Taoism, with its theory of a balance and interaction of cosmic forces, lent itself to elaboration and expression on all levels—from philosophy to pseudoscience to magic.

Religions of the West. In Western monotheistic religions it is necessary to distinguish between the role of miracles on the level of popular beliefs and practices and the theory of miracles propounded by the theologians. Belief in a personal, omnipotent Creator who exercises his providence over his creatures implies a concept of miracles as deliberate interventions in the course of events by the same sovereign God who also assures their normal regularity.

The Old Testament and rabbinic Judaism

Judaism. Miracles are taken for granted throughout the Old Testament. God does "wondrous things" according to Psalms, chapter 72, and "great things and unsearchable, marvellous things without number" according to the Book of Job, chapter 5; these things are done in his creation in general and in the history of his people in particular (*e.g.*, the 10 plagues of Egypt and the events of the Exodus). A list of the great wonders done by God is given in Psalms, chapter 136; their purpose is to make his creatures praise him, acknowledge his rule, and "know that I am the Lord." God's wondrous deeds range from the normal regularities of creation to extraordinary interventions that run counter to ordinary experience and thus serve as signs of his greatness and providence in wreaking vengeance on the wicked and giving salvation to his elect.

Later rabbinic Judaism took the occurrence of miracles for granted. It assumed a natural order in which things worked and within which humans were supposed to discharge their duties; thus, to rely on miracles was nothing short of sinful. In special circumstances, however, or in connection with persons of extraordinary saintliness, God would intervene or spectacularly answer their petitionary prayers. It was not so much a matter of suspending as of relativizing nature, the normal course of which was just one possible expression of the divine will. It was only in the Middle Ages and under the influence of Greco-Arabic philosophy that the problem of miracles was systematically discussed on a philosophical and theological level. Normative, rabbinic Judaism, being mainly concerned with doing God's will as revealed in his Law, had little interest in miracles, though it accepted, as a matter of course, the veracity of the miracles recorded in Scripture and in the Talmud (the collection of Jewish lore, legend, and law). On the level of popular piety both magic and the belief in miracles always flourished, especially under the influence of Kabbala, the esoteric, mystical movement within Judaism; the Ḥasidic movement (a pietist movement that arose in eastern Europe in the 18th century) in particular produced a rich crop of beliefs and legends concerning the miraculous virtue—through prayer, intercession, or magical power—of the great Ḥasidic saints and rabbis.

Jesus Christ

Christianity. New Testament accounts of the advent, birth, life, Passion, and Resurrection of Christ include many miracles. Jesus is reported in the Gospels to have performed miracles of diverse kinds: raising the dead, healing the sick, casting out demons, and causing nature miracles, such as the multiplication of loaves and the turning of water into wine at the town of Cana. Unlike the Buddha and Muḥammad, Jesus had an ambiguous attitude toward miracles: on the one hand he performed them as a sign of his mission and of the impending coming of the Kingdom; on the other hand he reproved the desire for wonders and repeatedly forbade the disciples to publicize his miracles, insisting that it was faith alone that worked miracles. In fact, because miracles also could be explained by attributing them to demonic agency, it was ultimately faith that determined the quality and function of the miracle.

Early Christianity developed in the atmosphere of Hellenistic, Greco-Roman culture, which was full of miraculous accounts and legends. These no doubt influenced Christian traditions and forms of devotion, especially as popular religion always hankered after miracles, and—at the conclusion of the Gospel According to Mark—Christ himself had promised the continuance of miracles in his church. In a world in which only a few critical minds doubted the reality of miracles, the similarity of the Christian signs to those reported in pagan legend was attributed to demonic imitation and counterfeit. The problem of distinguishing between the two sources of miracles—because the devil often disguises himself as an angel of light—frequently solicited the attention of theologians and mystics. Whereas for the theologians a miracle was a sign of God's saving presence and design, for the mass of believers it was the manifestation of a sacred power inherent in individual persons, places, and objects.

Medieval theologians—and specifically St. Thomas Aquinas—taught that as all knowledge was derived from sensible facts, so also "a certain degree of supernatural knowledge of the objects of faith" could be brought about "by certain supernatural effects that are called miracles." This doctrine already assumes a system of natural causality that God—though he normally works through the natural law of which he is the author and Creator—can temporarily set aside. It also assumes that—at least in theory, if not always in practice—natural and supernatural effects can be distinguished. Thus, in 1870 the first Vatican Council declared: "If anyone should say that no miracles can be performed, . . . or that they can never be known with certainty, or that by them the divine origin of the Christian religion cannot be rightly proved—let him be anathema." Belief in miracles is thus obligatory in the Roman Catholic Church, although belief in any specific miracle is not necessarily so. Classical Protestantism, however, has confined its belief in miracles to those recorded in Scripture.

Islām. Muslim religion assumes, as a matter of course, that Allāh works miracles and has done so in the past; *e.g.*, through Moses, Solomon, and Jesus but significantly not through the Prophet Muḥammad. According to the Qur'ān, Muḥammad explicitly rejected the idea of proving his vocation by signs and miracles: the Qur'ān itself was the greatest miracle, and he was but a human messenger and preacher of repentance. Nevertheless, subsequent narratives invested his birth and life with superlatively miraculous details.

The Prophet Muḥammad

Muslim popular religion—particularly under Ṣūfī (Islāmic mysticism) influence—abounds in miracles, pilgrimages to the tombs of wonder-working saints, and the like. Dogmatic theology, too, recognizes miracles as facts. The peculiar feature of Muslim theology is that, unlike Christian theology, it did not accept the idea of nature as an entity operating according to fixed laws ordained by the Creator. Because the universe is constantly being recreated by Allāh in successive time atoms, natural regularity is nothing but the regularity of Allāh's habit in recreating the universe. Thus, a miracle is the omnipotent God's departure from his habit but no different, in principle, from the latter. Muslim dogmatics distinguish between miracles (*karāmāt*), with which Allāh surrounds his saints (*awliyā'*) as a mark of distinction, and signs (*āyāt*, also *mu'jizāt;* literally, "acts of an overwhelming nature"). The latter are wrought by Allāh to prove the genuineness of his messengers and to overwhelm and reduce to silence their opponents. Such miracles, which deviate from the usual course of things and are of such nature that others cannot produce their like, are Allāh's testimony to the sincerity of his apostles. The problem is nevertheless complicated by the fact that Satan too can perform miracles. Generally speaking, miracles do not play a role in the continued life of orthodox Islām, though they loom large in popular belief and piety.

INTERPRETATION OF MIRACLES

All the more fully developed theologies have formulated a doctrine of miracles in the context of their beliefs regarding

God, the world, the operations of nature, and causality. The emergence of the concept of nature as a closed system functioning in accordance with strict causal laws created problems more than once, but medieval Christian and Jewish thought had no difficulty in maintaining that the order created by God could also be suspended by him.

In classical antiquity. Miracles were denied even in classical antiquity. Thus, Cicero asserted that "nothing happens without a cause, and nothing happens unless it can happen. When that which can happen does in fact happen, it cannot be considered a miracle. Hence, there are no miracles." Cicero qualified this statement, however, by saying that miracle stories may be necessary for the piety of ignorant folk. The 2nd-century pagan philosopher Celsus is less dogmatic in his attacks on Christianity: the Christian miracles are insufficiently attested and most improbable, but, even if they were genuine, they could hardly offset the miracles of the pagan world—*e.g.*, the healings of Asclepius. This was the standard pattern of many religious polemics: miracles as such were not necessarily denied; only those claimed by the adversary were denied. When these could not be denied, they were ascribed to diabolic agency or to the fraudulent practices of priests or occasionally to a misinterpretation of essentially natural phenomena.

Rationalist criticisms

In the 18th and early 19th centuries. Rationalist criticism, although not completely absent in the Middle Ages, became a major factor in the 18th and 19th centuries. David Hume, a British empiricist and a skeptic, in the chapter "On Miracles" in his *Enquiry Concerning Human Understanding* argued that, given the general experience of the uniformity of nature, miracles were highly improbable and that the evidence in their favour was far from convincing. It should be emphasized that Hume, whose criticism led him to a denial of causality, did not dismiss miracles because they were inconsistent with causal law—as many other thinkers did, notably the Deists (those, especially British, who advocated a natural religion). Instead Hume insisted on the probability factor and thus on the importance of assessing historical evidence. Because all Christians agreed that biblical religion and the scheme of salvation set forth in it could be maintained only by stressing prophecy and miracle, there developed a vast body of literature, especially among Protestants, proving the authenticity of the Christian faith on the basis of the miracles recorded in the Bible. For many 18th-century thinkers, however, the vastness and complexity of the order of nature were even more impressive than any alleged exceptions to it. Thus, belief in miracles, although remaining an essential element of faith to good Christians, appeared as sheer superstition to the eyes of the torchbearers of Rationalist enlightenment.

Criticism of the concept of miracle was articulated in more than one way. There was philosophical and scientific criticism to the effect that miracles were impossible and that even epistemologically (*i.e.*, within the limits of knowledge) the occurrence of a miracle could never be established; at most, these critics maintained, there were merely as yet unexplained natural phenomena. (This view comes close to the religious assertion that faith precedes the experience of a miracle and that the factuality of a miracle can never precede faith.) There was historical and philological criticism, arguing that the actual occurrence of miracles is unsubstantiated and analyzing the growth and evolution of the legends and texts reporting miracles. There was psychological criticism, arguing that some people want to believe in miracles and so produce imaginative creations answering their psychological needs. There was also a type of religious criticism implying that the truly spiritual has no need of miraculous supports. One suggested solution to the problem was the assertion that the term miracle does not describe an objective event but rather a subjective mode of experience. This view of Friedrich Schleiermacher, an early-19th-century Protestant theologian and philosopher, identified miracle with a religious understanding of any aspect of the world.

In the late 19th and 20th centuries. Later 19th- and 20th-century liberal Protestant thinkers, such as Rudolf Bultmann, a German New Testament scholar, discarded the traditional notion of miracle together with other elements of what they termed the mythological apparatus of the Bible. Many of these liberal theologians sought evidence for Christianity in the moral and religious transformation it brought to people's lives or interpreted the doctrine of salvation in Existential terms. The early decades of the 20th century, however, also witnessed a return to a more orthodox theological climate—as, for example, in the thought of Karl Barth, a Swiss Protestant theologian—and a new readiness to accept miracles as meaningful signs of God's salvific activity. This change of climate coincided with certain developments in science that appeared to question a too rigid and mechanical concept of causal determinism.

Liberal and Neo-orthodox Protestantism

Orthodox Jews, Christians, and Muslims still believe in the literal occurrence of the miracles recorded in their scriptures and traditions; Roman Catholics, furthermore, believe in the continued occurrence of miracles, defining them as a direct divine effect upon nature. The liberal attitude—whatever the variations in detail and in sophistication of the explanation—is essentially similar to that propounded by Schleiermacher. (R.J.Z.W./Ed.)

Saint

The phenomenon of saintliness (*i.e.*, the quality of holiness, involving a special relationship to the sacred sphere as well as moral perfection or exceptional teaching abilities) is widespread in the religions of the world, both ancient and contemporary. Various types of religious personages have been recognized as saints, both by popular acclaim and official pronouncement, and their influence on the religious masses (the broad spectrum of those holding various wide-ranging religious beliefs) has been, and is, of considerable significance.

NATURE AND SIGNIFICANCE

Saints are persons believed to be connected in a special manner with what is viewed as sacred reality—gods, spiritual powers, mythical realms, and other aspects of the sacred or holy. The existence of such persons has been a widespread phenomenon throughout the religions of the world. The religious person may have various relationships with the sacred: as seer, prophet, saviour, monk, nun, priest, priestess, or other such personage. In the case of each of these, however, a specific kind of relationship to the holy is involved. Seers, for example, have an inspirational vision of the future; prophets proclaim a revelation; saviours are entrusted with effecting redemption, liberation, or other salvatory conditions; monks and nuns lead religious lives in accordance with ascetic regulations that they generally observe as long as they live. Every one of these religious personages may simultaneously be, or become, a saint, but there is no necessary connection. Sainthood thus implies a special type of relationship to the holy, a relationship that is not automatically obtained by other religious personages through their performance of religious duties or offices.

Relationships with the sacred or holy

The significance of saintly personages is generally based on real or alleged deeds and qualities that became apparent during their lifetimes and continue to exert influence after their deaths. The special character of their feats and qualities of living is believed to arise from an especially close association with a deity or sacred power. In addition to such a relationship, sainthood also requires the existence of a sacral institution that can grant such recognition, or of a popular cult that acknowledges and posits a belief in the saint's special qualities. In institutionalized religions, such as Roman Catholicism, there is a regularized process (called canonization) by which saints are officially recognized. Canonization requires, among other things, proof that the person in question wrought miracles during his or her lifetime. On the other hand, folk belief often recognizes the saintly powers of a living or dead person long before the institutional religion acknowledges him as a saint.

SAINTS IN EASTERN RELIGIONS

Confucianism and Taoism. Confucianism is in the main ethically oriented. Confucius taught that right conduct was

The importance of right conduct

a means of acquiring ideal harmony with the Way (Tao) of Heaven and that the "holy rulers of primal times" were representative examples of such ideal conduct. In the oldest known Chinese historical work, the *Shu Ching* ("Classic of History"), such a ruler, King T'ang (11th century BC), is described as one who "possessed the highest degree of virtue, and so it came to be that he acquired the bright authority of Heaven." Thus, in Confucianism, the saintliness of its holy men lay in ethical perfection, and through the practice of ethical ideals a contact with Heaven (T'ien) was established. Confucius himself serves as an example of a man who was first regarded as a saint because of his deep wisdom and conscientious observance of ethical precepts and was even considered to be "more than human." During the Han dynasty (206 BC–AD 220), Confucius was elevated to a new status: Emperor Kao Tsu offered sacrifice at the Confucian temple, and Emperor Wu proclaimed Confucianism the official ideology of China. The titles duke (AD 1) and king (739) were further tributes to "the perfect sage." During the T'ang dynasty (618–907), sacrifices were regularly offered in Confucian temples, and in 1906 Confucius was declared equal to the Lord of Heaven.

Taoism is oriented toward another kind of sanctity: the attainment of a passionless unity with the Absolute. Chuang-tzu (died *c.* 300 BC), a mystical Taoist sage, speaks of the "pure men of early times" in his work, the *Chuang-tzu*, and characterizes them as such.

Shintō. Shintō, the native Japanese religion, is concerned with the veneration of nature and with ancestor worship; it does not have saints according to the standards of ethical perfection or of exceptionally meritorious performance. According to Shintō belief, every person after his death becomes a *kami*, a supernatural being who continues to have a part in the life of the community, nation, and family. Good men become good and beneficial *kamis*, bad men become pernicious ones. Being elevated to the status of a divine being is not a privilege peculiar to those with saintly qualities, for evil men also become *kamis*. There are in Shintō, however, venerated mythical saints—such as Ōkuni-nushi (Master of the Great Land) and Sukuma-Bikona (a dwarf deity)—who are considered to be the discoverers and patrons of medicine, magic, and the art of brewing rice.

Buddhism. Founded by Siddhārta Gautama, Buddhism developed into three major forms in the course of its more than 2,500-year history: Theravāda ("Way of the Elders"), also called in derogation Hīnayāna ("Lesser Vehicle"); Mahāyāna ("Greater Vehicle"); and, stemming from it, Vajrayāna ("Vehicle of the Thunderbolt"). A belief in saints prevails in all three groups.

Differing concepts of saints in Buddhism

Theravāda Buddhism, claiming strict adherence to the teachings of the Buddha, recognizes as saints (*arhats*) those who have attained Nirvāṇa (the state of bliss) and hence salvation from *saṃsāra* (the compulsory circle of rebirth) by their own efforts. The Buddha himself—having obtained Nirvāṇa ("the destruction of greed, . . . hate, . . . and illusion")—is viewed as the first Buddhist saint. Disciples of the Buddha who reached Nirvāṇa after him also are considered holy men. Furthermore, in early Buddhism, there were also women regarded as holy, including Prajāpatī, the Buddha's aunt and stepmother—whose repeated requests finally caused the Buddha to permit women to enter his order—and his wife Yaśodharā.

Mahāyāna saints

Mahāyāna Buddhism, originating about the beginning of the Christian Era, rejected the Theravāda belief that only monks may attain salvation. In Mahāyāna belief there is a path to redemption for all people, irrespective of their social standing. Salvation and the way to redemption are conceived in terms more liberal than those of Theravāda. Mahāyāna Buddhists believe in an otherworldly paradise that allows for personal existence and in which dwell heavenly Buddhas (those who have attained Nirvāṇa in previous worlds) and *bodhisattvas* ("Buddhas-to-be"). The heavenly Buddhas and *bodhisattvas* are believed to grant grace to sentient beings, so that salvation is no longer acquired by fleeing from the world and giving up worldly professions, but rather by faith (in the sense of trust) in the promise of a saviour deity. Thus, in Mahāyāna Buddhism, the Buddhas and *bodhisattvas* are viewed as the holy ones, the saints, who in compassion, attempt to aid others struggling for salvation. This concept is in striking contrast to the *arhats* of Theravāda Buddhism, who follow the dying Budddha's last words, "Seek *your own* salvation with diligence." The basic altruistic concept of Mahāyāna then is that of the helping *bodhisattva*. Everyone should strive for this ideal in order to save as many fellowmen as possible as a *bodhisattva* and to bring them into the "Greater Vehicle" (Mahāyāna). Hence, the idea of faith in benevolent saints gains prominence in Mahāyāna Buddhism as a theistic religion of salvation. In Japanese Mahāyāna there are patron saints, such as Shōtoku Taishi, the regent who supported the introduction and development of Buddhism in his country in about AD 600, after it had been introduced in AD 552.

Vajrayāna Buddhism, embodying, among other views, Tantrism (a system of magical and esoteric practices), is mainly represented by Tibetan Buddhism. In addition to the innumerable saints of Mahāyāna Buddhism, Tibetan Buddhism also accepts as living saints those who are regarded as incarnations (*tulkus*) of saints, scholars of the past, deities, or demons. The Dalai Lamas, heads of the Tibetan hierarchy, are viewed as reincarnations of Chenre-zi (the *bodhisattva* of mercy, Avalokiteśvara).

Jainism. According to Jain teaching, there were 23 Tīrthaṅkaras (saintly prophets or proclaimers of salvation) before Mahāvīra Vardhamāna, the 6th-century-BC Indian religious leader after whom Jainism was named. Today they are venerated as saints in temples containing their images. Veneration of the Holy Tīrthaṅkaras is viewed in terms of purifying the devotee morally, as these saints are but examples for the Jainas and not actually objects of a cult.

Hinduism. Hinduism in a wider sense encompasses Brahmanism, a belief in the Universal Soul, Brahman; in a narrower sense it comprises the post-Buddhist, caste-ordered religious and cultural world of India. The Indian religions are by and large mystical in character; hence, even in early Hinduism ascetics were highly honoured. Mysticism generally starts with ascetic practices as a means of eliminating a desire for worldly existence.

Significance of asceticism in the Hindu concept of saint

In later Hinduism, when the ascetics continued to be revered by the masses as *sādhus* (saints, or "good ones") and *yogis* (ascetic practitioners), the concept of the *avatāra* (the idea of the incarnation of a divine being in human form) served to interpret the existence of holy men. By means of this concept it was, and still is, possible to consider living and dead saints as incarnations of a deity and also to incorporate saints of other religions into the Hindu world of belief. Thus Jesus Christ, for instance, is regarded as an *avatāra* of the god Vishnu (Viṣṇu), and the Hindu saint Rāmakrishna is considered to be an *avatāra* of the god Śiva.

SAINTS IN WESTERN RELIGIONS

Ancient Greek religion. The ancient heroes of Greek religion may be regarded as saints. One basis for belief in heroes and the hero cult was the idea that the mighty dead continued to live and to be active as spiritual powers from the sites of their graves. Another source of the cult of heroes was the conception that gods were often lowered to the status of heroes. One of the best known heroes is Heracles, who became famous through his mighty deeds. In Greek religion the numinous (spiritual) qualities of a person lay in such heroic deeds.

Zoroastrianism and Parsiism. Zoroastrianism includes the veneration of Fravashis—*i.e.*, preexistent souls that are good by nature, gods and goddesses of individual families and clans, and physical elements. According to Zoroastrian belief, humans are caught up in a great cosmic struggle between the forces of good, led by Ahura Mazdā (Wise Lord), and the forces of evil, led by Angra Mainyu, or Ahriman, the Evil Spirit. In the battle between Asha (Truth) and Druj (Lie) the Fravashis may correspond to the saints of Roman Catholicism, who can be called upon for aid in times of trouble.

Judaism. The cult of saints in terms of veneration was not a part of the monotheistic religion of Israel. Saintliness,

however, was an ideal that many hoped to exhibit. The model of a pious person is depicted in the righteous one of Psalm 5, "his delight is in the law of the Lord, and on his law he meditates day and night." In the Hellenistic period (*c.* 300 BC—*c.* AD 300), when many Jews were susceptible to foreign religious influences, the Ḥasidim (the "pious" ones) segregated themselves from the others, holding fast to the faith of their fathers.

The Ḥasidim

The concept of the Ḥasidim gained new significance in the 18th century when Israel ben Eliezer, called Baʿal Shem Ṭov, or "Master of the Good Name," started the modern movement called Ḥasidism. As opposed to the Orthodox Israelite religion with its emphasis on rationalism, cultic piety, and legalism, Baʿal Shem Ṭov stood for a more mystically oriented form of Judaism.

Christianity. Jesus and his disciples did not speak of saints; but during the period (1st to early 4th century) in which they were persecuted, Christians began to venerate the martyrs as saints. They believed that the martyrs, being sufferers "unto death" for Christ, were received directly into heaven and could therefore be effective as intercessors for the living. By the 3rd century the veneration of martyr saints was already common.

In the Nicene Creed (AD 325) the early church called itself the "communion of saints." Here, however, the word "saint" has the broader meaning of "believer" rather than being applied strictly to a holy person or numinous personality worthy of veneration. In the 10th century a procedure of canonization (official recognition of a public cult of a saint) was initiated by Pope John XV. Gradually, a fixed process was developed for canonization by the pope, requiring that the person must have led a life of heroic sanctity and performed at least two miracles.

Saints in the Roman Catholic Church are venerated—but not worshipped—because of their spiritual and religious significance and are believed to be the bearers of special powers. Because of a belief in the powers of the saints, their relics are regarded as efficacious. In the Eastern Orthodox Church saints also are venerated, but the process of canonization is less juridical and not always ecumenical. In some Protestant churches (Lutheran and Anglican) saints are recognized, but not venerated as in the Roman Catholic and Orthodox.

Islām. Islām is a rigorously monotheistic religion, strictly prohibiting any kind of "conjunction" (*i.e.*, affiliation, or consortship) to Allāh. Thus the concept of sainthood was rejected. Yet even here a variegated belief in holy men arose because of the demands of popular religion. Over against the one distant God, whose almighty power and whose role as a strict judge was emphasized repeatedly, there emerged a desire for intercessors. These were found in saintly men who were believed to be endowed with charismatic powers (*karāmāt*), allowing them to go miraculously from one place to another far away; to wield authority over animals, plants, and clouds; and to bridge the gap between life and death. The Prophet Muḥammad (died AD 632) had negated the existence of saints, but the piety of the masses "canonized" holy men while they were still living. After they died, cults of devotion arose at the sites of their graves, and pilgrimages to such sites were believed to aid the believer in acquiring help and blessing.

Saintly powers of Muslim holy men

MODES OF RECOGNITION

The bases of recognition. The basic motive for the belief in and veneration of saints is, primarily, the recognition by people of religious persons whom they view as holy. In order for a religious personage (*e.g.*, prophet) to be recognized as a saint, it is necessary that other people see in him the aura of holiness. The holiness recognized in him may be an impersonal sacred or spiritual power—which is often perceived in quite insignificant persons—and is believed to be present even in the bones and other material relics of a recognized holy person after his death. Religious personalities also are believed to possess a personal holiness, either bestowed upon them by divine grace or acquired through ascetism and moral discipline. Such sanctity reveals itself in the power to perform miracles.

Recognition of forms of holiness

The highest form of holiness in a holy person is reflected in the interpretation of that person as an incarnation of divine reality or as the possessor of godly nature. Divine qualities are perceived in such a person, and through him, such as the Logos (divine Word, or Reason) in Jesus.

Popular recognition. Popular recognition of saints arises out of a predilection of the religious masses (those who maintain popular belief, or folk belief, along with beliefs officially promulgated) to grasp the supernatural in that which is believed to be unusual and uncommon—*i.e.*, in the miraculous event. Thus, the religious masses long for those who can perform wonders that are awe awakening and satisfy their desire for the miraculous and mysterious.

Besides the desire for miracles, there is another basic requirement of the masses, especially within monotheistic religions: the yearning for a superhuman being in human form. The one abstract God who is believed to be present everywhere and capable of helping everybody and everything is too unperceptual and remote for the average religious person. There is a tendency among the religious masses to split up the deity into many numinous beings that fulfill the desires of the people. The religious masses often have polytheistic tendencies. The term "dear saints," as the holy ones are called in Roman Catholicism, expresses an emotional relationship to those near, benevolent, heavenly, or spiritual powers that are the heirs to the ancient ethnic and patron deities of pre-Christian times.

In the course of their histories, and as they expand, the great universal religions (*e.g.*, Christianity, Buddhism, and others) incorporate ever more people with their particular folk beliefs. As their numbers grow and their influence increases in the religious communities, the indigenous peoples retaining many earlier folk beliefs form the majority and their inclinations prevail. Because their behaviour patterns generally remain constant, their religious forms are preserved. Occasionally, religious reform movements arise within the organized mass religions. Such movements attempt to restore what is believed to be the original form of the respective religions and often turn against a belief in and veneration of saints, regarding such forms of religiosity as degenerate. This was the case in the 16th-century Protestant Reformation and also in the Wahhābiyah movement, an 18th-century reform movement in Islām.

Theological interpretations of popular recognition. In monotheistic religions the belief in saints in its popular form generally contradicts orthodox teaching. Such religiosity is usually opposed and rejected or else reinterpreted in view of its ineradicability. If the latter is the case, the orthodox interpretation given the cult of saints in order to justify it is a theological construction. In Roman Catholicism, for instance, church doctrine makes a distinction between veneration (*veneratio, douleia*) and adoration (*adoratio, latreia*). Veneration is defined as a proper attitude toward saints, whereas adoration is applicable only in connection with God. The veneration of images as practiced especially in the Eastern Orthodox Church is explained similarly. The Roman Catholic Church also teaches that the saints are representatives of God's grace on earth and that they are completely subject to his will. The vestigial remains of polytheistic beliefs and practices connected with the veneration of saints are thus theologically, though not popularly, eliminated.

Theological distinctions of forms of veneration

Similar interpretations of the belief in saints in a monotheistic religion serve to justify an existing cult. The people themselves are hardly influenced by such interpretations, however. According to many scholars, the differentiation between *douleia* (veneration) and *latreia* (worship), or between *veneratio* (veneration) and *adoratio* (adoration), has little meaning for the masses. In practice, they observe their cult of saints quite in accordance with polytheistic devotion toward gods. The supplications actually directed to the saints in the various religions can hardly be distinguished from prayers to deities, even though the saints are theologically regarded as mere intercessors having special access to God, and the answer to prayer is considered as coming from God alone. From the perspective of scholars of comparative religion, however, beings to whom prayers are dedicated are gods.

Forms of cults. The form of a cult of saints can be categorized as either *indirect* or *direct*. An indirect cult form

Indirect and direct cultic forms

involves the veneration of objects that stand in a magical relationship with the respective saint. In this connection there can be a veneration of the saint's relics. Such religious practices are to be understood in terms of spiritual power. Numinous power is viewed as issuing from the saint; and it is believed to be acquired by veneration or, in practice, mainly by touching (or kissing) the object itself. Another indirect cult form is the veneration of the image of the saint. According to primitive belief, there is a magical connection between the image and the original, which is itself holy. A common and widespread custom is the depositing of votive offerings, dedicated to certain saints, at holy places—temples, churches, shrines, or chapels where the supplicant can be certain of their direct presence and aid. This custom is of ancient origin—*e.g.*, the votive offerings dedicated to the healing god Asclepius in the museum of Epidaurus (Greece). This practice is still to be found in present-day popular belief in Greece or at Roman Catholic places of pilgrimage.

In these forms of indirect cult, then, saints are venerated through the medium of concrete objects. In direct veneration, on the other hand, the saint himself is addressed in invocation and praise. According to popular belief, such direct worship is most effective at the place of the predominant presence of the respective saint. The idea of pilgrimage is always based upon such a belief in the localized presence of numinous power.

TYPES AND FUNCTIONS OF SAINTS

Saints as moral examples. A classical illustration of the saint who is distinguished by his virtue is St. Francis of Assisi. Giving up a life of extravagance, he began in 1209, together with several friends, to actualize his ideal of the imitation of Christ by leading a life of poverty. For St. Francis, three virtues constituted the preconditions of true divine vision: poverty, ascetic chastity, and humility.

An example of a similar kind of saintliness is reflected in the person of the Indian leader and reformer Mahatma Gandhi (1869–1948). In his life, devoted to the acquiring of freedom for India, he also lived according to three ideals. The first was *satyāgraha,* holding fast to the truth with all the powers of the spirit. Gandhi's second basic principle was *ahiṃsā,* which is to be understood not only in the negative sense of "not killing" but also positively as a renunciation of the self and an indulgence in "kind actions" toward all beings. His third ideal was *brahmacarya,* which often is rendered too narrowly as chastity; it is the ascetic way of life that Gandhi followed as a saint and as a statesman, hence receiving boundless veneration by the masses.

Saints as prophets and reformers. Many prophets and prophetic reformers form a second group of saints. One prophet in early Christianity was Paul, who is honoured as a saint by Roman Catholics, Eastern Orthodox, and Protestants. He was a most powerful spiritual personality, decisively and significantly involved in the development of Christianity from a Jewish sect to a world religion.

The Tibetan reformer Tsong-kha-pa belonged to a completely different world from that of St. Paul. Originally, he did not want to be an innovator but only a renewer of old religious patterns. He was mainly concerned with the restoration of the discipline and the development of the Lamaistic cult. His fame grew, and owing to his activity many monasteries were founded. The "Yellow Hat" sect was established by him. According to legend, Tsong-kha-pa was taken up to heaven before the eyes of the people. This accounts for the veneration he received, and still receives, by the Tibetan people.

Theological teachers as saints. Often numbered among the saints are certain religious personalities whose significance lies in their work as illuminating interpreters of religious tradition or as proponents of a new view of the divine or the eternal. An example from Indian religions is the great teacher (*ācārya*) Śaṅkara, the representative of Advaita (the teaching of the nonduality of divine reality). When he died at the age of 32, a short and outwardly uneventful life lay behind him. Yet even today the personality and work of Śaṅkara continue to determine the intellectual and religious life of India. Equally significant in the Christian West, and specifically in the Roman Catholic Church, is Thomas Aquinas, a Dominican scholar. Although first disputed, his work finally received general recognition, and he became recognized as the *doctor communis* ("general teacher") of the Roman Catholic Church. His significance lies in his encompassing and methodically clear theological and philosophical system, in which he reconciled the views of the ancient Greek philosopher Plato with those of his student Aristotle, antiquity with Christianity, knowledge with faith, and nature with grace. He was proclaimed a saint in 1323. (G.Me./Ed.)

BIBLIOGRAPHY

General. HEINRICH EMIL BRUNNER, *Dogmatik,* vol. 1 (1946; Eng. trans., *Dogmatics,* vol. 1, *The Christian Doctrine of God,* 1949), advocates the primacy of Scripture over tradition; OWEN CHADWICK, *From Bossuet to Newman: The Idea of Doctrinal Development* (1957), an excellent survey of the gradual shift from "the classical consciousness" of identity in doctrine (Bossuet) to a "historical consciousness" of growth and continuity (Newman); ADOLF VON HARNACK, *Lehrbuch der Dogmengeschichte,* 3rd ed., 3 vol. (1893; Eng. trans., *History of Dogma,* 7 vol., 1900, reprinted 1961), a massive exposition of the thesis that Christian dogma represents the process of Hellenization of the original Gospel, hence a deviation; JOHN HENRY NEWMAN, *An Essay on the Development of Christian Doctrine,* new ed. (1878), a classical statement of the emergence of the historical consciousness within the Catholic tradition; J. PELIKAN, *Development of Christian Doctrine: Some Historical Prolegomena* (1969), an important statement of the interaction of Scripture and tradition in the formation of Christian doctrines and dogmas; FREDERICK J. STRENG, *Understanding Religious Man* (1969), an excellent summary of the common elements in religious experience, including those relating to doctrine and dogma; R.C. ZAEHNER, *Concordant Discord: The Interdependence of Faiths* (1970), helpful insights as to the various ideas of authority in the major religions of the world.

Creation. *Cosmogonic myths:* CHARLES H. LONG, *Alpha: The Myths of Creation* (1963), gives examples of various types of cosmogonic myths from different cultures. For ancient Near Eastern myths, see *Ancient Near Eastern Texts Relating to the Old Testament,* ed. by JAMES B. PRITCHARD, 3rd ed. with suppl. (1969). JOHANNES PEDERSEN, *Israel,* 4 vol. (Eng. trans. 1926–40), is a cultural-religious study that shows the relationship between creation myth, land, and kinship system. For the nature and structure of myths and symbols, see ERNST CASSIRER, *Philosophie der symbolischen Formen,* 4 vol. (1953–56; Eng. trans., *The Philosophy of Symbolic Forms,* 3 vol., 1953–55); and JOAN O'BRIEN and WILFRED MAJOR, *In the Beginning: Creation Myths from Ancient Mesopotamia, Israel, and Greece* (1982).

The development and structure of Greek myths: JOHN BURNET, *Early Greek Philosophy,* 4th ed. (1930, reprinted 1963), is a well-written interpretation of the pre-Socratic myths of creation. ARNOLD EHRHARDT, *The Beginning* (1968), shows the common structure of the cosmologies of the Gospel According to John and pre-Socratic thinkers.

Christian doctrine: For a theological history of the Christian doctrine of creation in its variety and continuity, see JAROSLAV PELIKAN, *Development of Christian Doctrine* (1969), *The Christian Tradition* (1971), and *Historical Theology: Continuity and Change in Christian Doctrine* (1971). JOHN MACQUARRIE, *Principles of Christian Theology* (1966), presents a structural and systematic analysis of the elements of Christian theology, showing how the doctrine of creation fits into theological systems.

Islām: DE LACY O'LEARY, *Arabic Thought and Its Place in History,* rev. ed. (1939, reprinted 1963), deals with the internal and external sources of Arabic philosophy and cosmology. SEYYED HOSSEIN NASR, *An Introduction to Islamic Cosmological Doctrines* (1964), explicates a tradition in Arabic thought that expresses creation in symbolic and cosmological images.

Zoroastrianism: Several Zoroastrian myths and doctrines of creation are found in R.C. ZAEHNER, *The Dawn and Twilight of Zoroastrianism* (1961).

Chinese philosophy: ARTHUR F. WRIGHT (ed.), *Studies in Chinese Thought* (1953), brings together 10 essays on various aspects of Chinese thought; most valuable is DERK BODDE, "Harmony and Conflict in Chinese Philosophy," pp. 19–80. For a history of Chinese philosophical speculation as it relates to cosmogony and cosmology, see FUNG YU-LAN, *A History of Chinese Philosophy,* 2nd ed., 2 vol. (1952–53).

Indian philosophy: Speculations about creation in the various schools of Indian philosophy can be found in SURENDRANATH DAS GUPTA, *A History of Indian Philosophy,* 5 vol. (1922–55). ALAIN DANIELOU, *Le Polythéisme hindou* (1960; Eng. trans., *Hindu Polytheism,* 1964), is a description and interpretation of the gods of Hinduism in relationship to their philosophical

meaning. T.R.V. MURTI, *The Central Philosophy of Buddhism* (1955), is an explication of the Mādhyamika system of Buddhist philosophy that denies creation.

Comparative works: HAJIME NAKAMURA, *Ways of Thinking of Eastern Peoples* (1964), is a comparative work showing the similarities and contrasts between Indian, Chinese, Tibetan, and Japanese modes of thought especially as they concern creation. C.F. VON WEIZSACKER, *The Relevance of Science: Creation and Cosmogony* (1964), deals with the evolution of thought about creation from myth to scientific theory. CHARLES HARTSHORNE and WILLIAM REESE (eds.), *Philosophers Speak of God* (1953), explores the rational bases for several conceptions of God and creation in Eastern and Western thought.

Eschatology. *General:* M. ELIADE, *Le Mythe de l'éternel retour* (1949; Eng. trans., *The Myth of the Eternal Return,* 1954), an internationally recognized standard work; T. ROSZAK, *The Making of a Counter Culture* (1969), a discussion of the formation of secular messianic movements in modern society; W.D. WALLIS, *Messiahs: Their Role in Civilization* (1943); GAYRAUD S. WILMORE, *Last Things First* (1982), a scholarly discussion of eschatology as it has existed in various cultures and religions.

Biblical: R.H. CHARLES, *Eschatology: The Doctrine of a Future Life in Israel, Judaism and Christianity* (1899, reprinted 1963), a comparison of ideas; O. CULLMANN, *Christus und die Zeit,* 3rd ed. (1962; Eng. trans., *Christ and Time,* 1962); R.K. BULTMANN, *History and Eschatology* (1957), an existentialist interpretation of eschatology; P.S. MINEAR, *The Christian Hope and the Second Coming* (1954), an integral biblical view; R.J. ZWI WERBLOWSKY, "Messianism in Jewish History," *Journal of World History,* 11:30–45 (1968), with a bibliography; and N.R.C. COHN, *The Pursuit of the Millennium,* 2nd ed. (1961; rev. paperback ed., 1970).

Theological and philosophical: M. SCHMAUS, *Von den letzten Dingen* (1948), the best Roman Catholic treatise on eschatology; N. BERDYAEV, *The Beginning and the End* (1957, orig. pub. in Russian, 1947), Russian Orthodox philosophy of religion; J.A.T. ROBINSON, *In the End, God* (1968), an introduction to this subject; P. TEILHARD DE CHARDIN, *Le Phénomene humain* (1956; Eng. trans., *The Phenomenon of Man,* 1959), a discussion combining eschatology with the theory of evolution; J. MOLTMANN, *Theologie der Hoffnung,* 8th ed. (1964; Eng. trans., *Theology of Hope,* 1967), on the beginning of the ecumenical theology-of-hope movement.

Angels and demons. C. JOUCO BLEEKER and GEO WIDENGREN (eds.), *Historia Religionum: Handbook for the History of Religions,* vol. 1, *Religions of the Past* (1969), and vol. 2, *Religions of the Present* (1971), contains helpful sections on the role of angels and demons in chapters on the various religions, as well as a very usable bibliography. J.B. NOSS, *Man's Religions,* 4th ed. (1969), contains useful sections on angels and demons. GUSTAV DAVIDSON, *A Dictionary of Angels, Including the Fallen Angels* (1967); and ROSSELL H. ROBBINS, *The Encyclopedia of Witchcraft and Demonology* (1959), are Western-oriented. R.C. ZAEHNER, *The Dawn and Twilight of Zoroastrianism* (1961), has excellent sections on the role of angels and demons in Zoroastrianism and their relationship to Hindu spiritual beings. ROBERT M. GRANT, *Gnosticism and Early Christianity,* 2nd ed. (1966), contains useful sections relating angelic and demonic figures of Judaism, Christianity, and Zoroastrianism to Gnostic speculation. See also JEFFREY B. RUSSELL, *Satan: the Early Christian Tradition* (1981).

Salvation. For recent and comprehensive studies of the subject, S.G.F. BRANDON, *Man and His Destiny in the Great Religions* (1962), provides extensive documentation and bibliographies; important aspects of salvation are specially dealt with in his *History, Time and Deity* (1965) and *The Judgment of the Dead* (1967). S.G.F. BRANDON (ed.), *The Saviour God* (1963), comprises 15 essays by specialists in the major religions. A valuable and well-documented study of the subject in Hebrew, Greco-Roman religions, and early Christianity may be found in T. KLAUSER (ed.), *Reallexikon für Antike und Christentum,* vol. 5, col. 54–219 (1964). ADOLF VON HARNACK's monumental *Lehrbuch der Dogmengeschichte,* 3rd ed., 3 vol. (1893; Eng. trans., *History of Dogma,* 7 vol., 1900, reprinted 1961), traces the development of Christian soteriology. L.W. GRENSTED, *A Short History of the Doctrine of the Atonement* (1920, reprinted 1962), is a reliable concise guide. Aspects of salvation in the religions concerned are treated in the following books: R.C. ZAEHNER, *Hinduism,* 2nd ed. (1966) and *The Dawn and Twilight of Zoroastrianism* (1961); E.J. THOMAS, *The History of Buddhist Thought,* 2nd ed. (1951); and A.J. WENSINCK, *The Muslim Creed* (1932).

Providence. No general introduction to the subject written from the point of view of the science of religion exists, but useful articles are found in some specialized encyclopaedias, such as *Hastings' Encyclopaedia of Religion and Ethics* (1919). Further information has to be gathered from monographs about specific problems related to Providence, *e.g.,* JOHN BOWKER, *Problems of Suffering in the Religions of the World* (1970).

Revelation. R.C. ZAEHNER, *At Sundry Times* (1958), a sympathetic approach by an accomplished scholar who finds anticipations of Christian revelation not only in Judaism but also in Hinduism, Buddhism, and Zoroastrianism; J.H. WALGRAVE, *Un salut aux dimensions du monde,* trans. from the Dutch (1970), an apologetically oriented work that attempts to bring out the distinctive qualities of the Christian view of revelation in comparison with Buddhism, Hinduism, and Islām.

Primitive religion: MIRCEA ELIADE, *Traité d'histoire des religions* (1948; Eng. trans., *Patterns in Comparative Religion,* 1958), a discussion of hierophanies, myths, and symbols as pertinent to the theme of revelation; G. VAN DER LEEUW, *Phänomenologie der Religion* (1933; Eng. trans., *Religion in Essence and Manifestation,* 2 vol., 1963), a phenomenological approach influenced by Rudolf Otto and others.

Christianity: A.R. DULLES, *Revelation Theology: A History* (1969), a survey of Catholic and Protestant views; J. BAILLIE, *The Idea of Revelation in Recent Thought* (1956), a sketch of trends in 20th-century Protestant theology; CARL F. HENRY, *God, Revelation and Authority,* 6 vol. (1976–83), an evangelical's argument for the infallibility of biblical revelation.

Islām: A.J. ARBERRY, *Revelation and Reason in Islam* (1957), a concise and learned treatment of the medieval controversies; K. CRAGG, *The Call of the Minaret,* pt. 2, pp. 33–171 (1956), a very objective presentation of Muslim faith and piety, including some discussion of the doctrine of revelation.

Hinduism: K.S. MURTY, *Revelation and Reason in Advaita Vedānta* (1959), an exposition and evaluation of Śaṅkara's position in the light of modern Western philosophy; R.C. ZAEHNER, *Hindu and Muslim Mysticism* (1960), on the love relationship to God in Bhakti and Ṣūfism.

Buddhism: W.L. KING, *Buddhism and Christianity: Some Bridges of Understanding* (1962), an objective comparison between Christianity and Theravāda Buddhism, with a good discussion of the revelatory role of the Buddha.

Judaism: A.J. HESCHEL, *God in Search of Man,* pt. 2, pp. 167–278 (1956), a presentation of modern Judaism by a prominent rabbinic scholar.

Covenant. W. BEYERLIN, *Herkunft und Geschichte der ältesten Sinai traditionen* (1961; Eng. trans., *Origins and History of the Oldest Sinaitic Traditions,* 1966); G.E. MENDENHALL, "Covenant," *Interpreter's Dictionary of the Bible,* vol. 1, pp. 714–723 (1962); R.C. DARNELL, *Idea of Divine Covenant in the Qur'an* (1970); D.J. MCCARTHY, *Treaty and Covenant* (1963); "Egyptian and Hittite Treaties" in J.B. PRITCHARD (ed.), *Ancient Near Eastern Texts Relating to the Old Testament,* 2nd ed., pp. 199–206 (1955); D.R. HILLERS, *Covenant: The History of a Biblical Idea* (1969); JONATHAN BISHOP, *The Covenant* (1982), a look at covenants in the Old and New Testaments and an attempt to apply the concept to today's world.

Prophecy. *General:* G. HOLSCHER, *Die Propheten* (1914), a classic; A.J. HESCHEL, *The Prophets* (1962), a theological comparison between Israelite and non-Israelite prophets; J. LINDBLOM, *Prophecy in Ancient Israel* (1962), a good introduction to the phenomenological, psychological, and theological problems of prophecy; R.B.Y. SCOTT, *The Relevance of the Prophets,* 2nd ed. (1968).

Prophecy in the ancient Middle East and Israel: A. GUILLAUME, *Prophecy and Divination Among the Hebrews and Other Semites* (1938), a standard work; D.R. HILLERS, *Treaty-Curses and Old Testament Prophets* (1964); A.L. OPPENHEIM, *Ancient Mesopotamia: Portrait of a Dead Civilization* (1964); R.E. CLEMENTS, *Prophecy and Covenant* (1965), a valuable study of the available prophetical texts from Mari thus far; N.K. GOTTWALD, *All the Kingdoms of the Earth* (1964), on prophets and politics; E. HAMMERSHAIMB, *Some Aspects of Old Testament Prophecy from Isaiah to Malachi* (1966), dealing with the Canaanite, cultic, and historical background; A.R. JOHNSON, *The Cultic Prophet in Ancient Israel,* 2nd ed. (1962); J. PEDERSEN, *Israel,* 4 vol. (1926–40), a classic on religious life and institutions; H. RINGGREN, *Israelite Religion* (1966).

Prophecy in Christianity: L. HARTMAN, *Prophecy Interpreted* (1966); H.A. GUY, *New Testament Prophecy* (1947); G. FRIEDRICH, "Prophets and Prophecies in the New Testament," *Theological Dictionary of the New Testament,* vol. 6, pp. 828–861 (1968); S. UMEN, *Pharisaism and Jesus* (1963).

Prophecy in Islām: T. ANDRAE, *Mohammed: The Man and His Faith* (Eng. trans. 1956); S. FUCHS, *Rebellious Prophets* (1965); A. GUILLAUME, *Islam,* new ed. (1963); P.K. HITTI, *Islam: A Way of Life* (1970); W. MONTGOMERY WATT, "Muḥammad," *The Cambridge History of Islam,* vol. 1, pp. 30–56 (1970).

Prophetic movements and figures in Eastern and primitive religions: I. HORI, *Folk Religion in Japan: Continuity and Change,* ed. by J.M. KITAGAWA and A.L. MILLER (1968); E.R.

and K. HUGHES, *Religion in China* (1950); B.G.M. SUNDKLER, *Bantu Prophets in South Africa*, 2nd ed. (1961); M. WEBER, *The Religion of China*, trans. by H.H. GERTH (1968).

Miracle. GUSTAV MENSCHING, *Das Wunder im Glauben und Aberglauben der Völker* (1957), the best and most complete treatment of the subject; ROBERT M. GRANT, *Miracle and Natural Law in Graeco-Roman and Early Christian Thought* (1952), a description of Hellenistic attitudes and beliefs. BENEDICTA WARD, *Miracles and the Medieval Mind: Theory, Record, and Events, 1000–1215* (1982), a study of the attitudes toward reports of miracles by the church and by other institutions.

Saint. H. RINGGREN and A.V. STROM, *Die Religionen der Völker* (1959; Eng. trans. from the 3rd Swedish ed., *Religions of Mankind Today and Yesterday*, 1967), gives information on the significance of saints. The cult of saints is dealt with in connection with the phenomenology of religion by G. MENSCHING, *Die Religion* (1959). See also W.J. BURGHARDT, *Saints and Sanctity* (1965). The characteristics and the actions of holy men in non-Christian religions are treated in R.A. NICHOLSON, *The Mystics of Islam* (1914, reprinted 1963); W.T. DE BARY *et al.* (comps.), *Sources of Chinese Tradition* (1960); and G. VON GRUNEBAUM, *Medieval Islam*, 2nd ed. (1953). In the realm of Christianity, P. MOLINARI, *I Santi e il loro culto* (1962; Eng. trans., *Saints: Their Place in the Church*, 1965), gives information concerning the veneration of saints in folk piety. The veneration of saints in the Eastern Church is canvassed by D. ATTWATER, *Saints of the East* (1963).

Dogs

The dog is one of the two most ubiquitous and popular domestic animals in the world (the cat is the other). For more than 12,000 years the dog has lived with humans as a hunting companion, protector, object of scorn or adoration, and friend. The dog has evolved from similar (that is, undifferentiated) fur-bearing animals into more than 400 distinct breeds. Human beings have played a major role in creating dogs that fulfill distinct societal needs. Through the most rudimentary form of genetic engineering, dogs were bred to accentuate instincts that were evident from their earliest encounters with humans. Although details about the evolution of dogs are uncertain, the first dogs were hunters with keen senses of sight and smell. Humans developed these instincts and created new breeds as need or desire arose.

Dogs are regarded differently in different parts of the world. Western civilization has given the relationship between human and dog great importance, but, in some of the developing nations and in many areas of Asia, dogs are not held in the same esteem. In some areas of the world, dogs are used as guards or beasts of burden or even for food, whereas, in the United States and Europe, dogs are protected and admired. In ancient Egypt during the days of the pharoahs, dogs were considered to be sacred.

Characteristics of loyalty, friendship, protectiveness, and affection have earned dogs an important position in Western society, and in the United States and Europe the care and feeding of dogs has become a multibillion-dollar business.

All dogs belong to the family Canidae, along with their relatives—wolves, jackals, and foxes. They are members of the mammalian order Carnivora, or "Flesh Eaters." Although there are more than 400 different dog breeds, all dogs belong to a single species, *Canis familiaris*.

Dogs have played an important role in the history of human civilization and were among the first domesticated animals. They were important in hunter-gatherer societies as hunting allies and bodyguards against predators. When livestock were domesticated about 7,000 to 9,000 years ago, dogs served as herders and guardians of sheep, goats, and cattle.

Although many still serve in these capacities, dogs are increasingly used for social purposes and companionship. Today, dogs are employed as guides for the blind and disabled or for police work. Dogs are even used in therapy in nursing homes and hospitals to encourage patients toward recovery. Humans have bred a wide range of different dogs adapted to serve a variety of functions. This has been enhanced by improvements in veterinary care and animal husbandry.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 313, and the *Index*. This article is divided into the following sections:

ORIGIN AND HISTORY OF DOGS

Ancestry. Paleontologists and archaeologists have determined that about 60 million years ago a small mammal, rather like a weasel, lived in the environs of what are now parts of Asia. It is called *Miacis*, the genus that became the ancestor of the animals known today as canids: dogs, jackals, wolves, and foxes. *Miacis* did not leave direct descendants, but doglike canids evolved from it. By about 30 to 40 million years ago *Miacis* had evolved into the first true dog—namely, *Cynodictis*. This was a medium-size animal, longer than it was tall, with a long tail and a fairly brushy coat. Over the millennia *Cynodictis* gave rise to two branches, one in Africa and the other in Eurasia. The Eurasian branch was called *Tomarctus* and is the progenitor of wolves, dogs, and foxes.

It is believed that the early dogs dating from about 12,000 to 14,000 years ago came from a small strain of gray wolf that inhabited what is now India. Thereafter, this wolf—known as *Canis lupus pallipes*—was widely distributed throughout Europe, Asia, and North America. It is also

possible that some of the dogs of today descended not from the wolf but rather from the jackal. These dogs, found in Africa, might have given rise to some of the present native African breeds.

No matter what their origins, all canids have certain common characteristics. They are mammals that bear live young. The females have mammary glands, and they suckle their offspring. The early breeds had erect ears and pointed or wedge-shaped muzzles, similar to the northern breeds common today. Most of the carnivores have similar dental structures, which is one way paleontologists have been able to identify them. They develop two sets of teeth, deciduous ("baby") teeth and permanent teeth.

Canids walk on their toes, in contrast to an animal like the bear, which is flat-footed and walks on its heels. Dogs, like most mammals, have body hair and are homeothermic—that is to say, they have an internal thermostat that permits them to maintain their body temperature at a constant level despite the outside temperature.

Fossil remains suggest that five distinct types of dogs existed by the beginning of the Bronze Age (about 4500 BC). They were the mastiffs, wolf-type dogs, sight hounds (such as the Saluki or greyhound), pointing dogs, and herding dogs.

First encounter with humans

Domestication. It is uncertain when the first dog became a companion of humans, but it is likely that wild canids were scavengers near tribal campsites at the same time that ancient humans discovered a hunting partner in the animals that ventured close by. In ancient Egypt, dogs were thought to possess godlike characteristics. They were pampered by their own servants, outfitted with jeweled collars, and fed the choicest diet. Only royalty was permitted to own purebred dogs, and upon the death of a ruler his favourite dog was often interred with him to protect him from harm in the afterlife.

Illustrations of dogs dating from the Bronze Age have been found on walls, tombs, and scrolls throughout Europe, the Middle East, and North America. Often the dogs are depicted hunting game with their human counterparts. Statues of dogs guard the entrances to burial crypts. In many cases these dogs clearly resemble modern canines. Such relics are indelible testimony to the importance that humans have given to the dog throughout the ages.

Origin of breeds. Once it became evident that dogs were faster and stronger and could see and hear better than humans, those specimens exhibiting these qualities were interbred to enhance such attributes. Fleet-footed sight hounds were revered by noblemen in the Middle East, while in Europe powerful dogs such as the mastiff were developed to protect home and traveler from harm.

As society changed and agriculture—in addition to hunting—became a means of sustaining life, other breeds of dogs were developed. Herding and guarding dogs were important to farmers for protecting their flocks. At the same time, small breeds became desirable as playthings and companions for noble families. The Pekingese in China and fragile breeds such as the Chihuahua were bred to be lapdogs. The terrier breeds were developed, mainly in England, to rid granaries and barns of rodents. Pointing and retrieving breeds were selected for special tasks related to aiding the hunter to find and capture game. Many breeds are extremely ancient, while others have been developed as recently as the 1800s.

PHYSICAL TRAITS AND FUNCTIONS

General characteristics. Dogs come in a wide range of shapes and sizes. It is difficult to imagine that a large Great Dane and a tiny poodle are of the same species, but they are genetically identical with the same anatomic features. All dogs have 78 chromosomes, or 39 pairs of chromosomes (humans have 23 pairs). One member of each pair comes from each parent.

Teeth. Dogs have two sets of teeth. Twenty-eight deciduous teeth erupt by six to eight weeks of age, and by the time puppies are six to seven months old these deciduous teeth are all replaced by 42 adult teeth. The permanent teeth include incisors, which are used to nip and bite; canines, which tear and shred flesh; and premolars and molars, which shear and crush. In short, a dog's teeth serve as weapons and as tools for cutting or tearing food. The canines are the upper and lower fangs for which the dog family was named. As in most carnivores, the teeth are high-crowned and pointed, unlike the broad, grinding teeth of many herbivorous animals.

The teething process can be difficult for puppies. Their gums hurt and become swollen, they may lose their appetites, and they may have mild intermittent diarrhea.

Digestive system. Dogs rarely chew their food. Once the food is taken into the mouth, it is gulped or swallowed and passed through the esophagus into the stomach, where digestive enzymes begin to break it down. Most of the digestion and absorption of food takes place in the small intestines with the aid of the pancreas and the liver. The pancreas secretes enzymes needed for regulating the digestive process. As in humans, the pancreas produces insulin and glucagon, both of which are necessary for the regulation of glucose. The liver is the largest internal organ in the body. It has six lobes (whereas the human liver has only two). The liver is responsible for many essential life-preserving functions. It helps digestion by producing bile, which aids in the absorption of fat. The liver also metabolizes protein and carbohydrates, and it excretes toxins from the bloodstream. In addition, it manufactures major blood-clotting agents. Because the liver performs all these vital functions, liver disease can be a major problem in dogs.

Skeletal structure. The skeletal frame of the dog consists of 319 bones. If a dog's tail is docked or absent at birth, there obviously are fewer bones in the skeleton. The muscles and tendons of a dog are similar to those of a human; however, a dog's upper body muscles bear half the weight of the entire body and are better developed than a human's. The weight distribution between the front and the rear of the dog are relatively equal.

Dogs are running animals, with the exception of those bred specifically for different purposes. For instance, the bulldog, with its large head and short, "bowed" legs, cannot be called a creature born to chase game. Most dogs, however, are well equipped to run or lope over long distances, provided that they are physically conditioned for such activities. The construction of the shoulder and pelvic bones and the way they articulate with the leg bones and the spine allow most breeds to trot, run, or gallop with ease. Certain breeds have distinct gaits that have been genetically selected by humans. The German shepherd dog is known for its "flying trot." The extreme extension of the front and rear legs causes the dog to appear as if it were soaring, although one foot always remains on the ground. Another unique gait is that of the greyhound. This dog was bred for great bursts of speed, and its most comfortable gait is the gallop. The spine is unusually flexible, allowing the dog to contract and extend its four legs in unison, whereby all four feet are off the ground at the same time.

Bone construction

Other breeds also have unique features. The Afghan hound was bred to chase game over long distances in rocky terrain. Its structure permits great flexibility through the hip joints and lower back, enabling the dog to turn quickly in a small area. The dachshund, by contrast, is long and low with short legs. This dog was bred to hunt badgers underground, and its shape allows it to enter subterranean tunnels in search of its prey.

Although most breeds no longer follow the pursuits for which they were originally bred, their instincts remain strong, and their structure still allows them to perform their specific tasks.

Senses. Dogs have the same five senses as humans. However, some are more highly developed, and others are deficient compared with those of humans. Dogs' sense of smell is by far the most acute and is immeasurably better than that of humans. Dogs are used for such tasks as tracking missing persons, digging underground, and tracing toxic substances, such as gases, that are undetectable by humans. Dogs can detect drugs, explosives, and the scents of their masters. Not all canine noses are the same, however. Some breeds, such as the German shepherd and the bloodhound, have much more keenly developed olfactory senses than others. One would not choose a short-nosed breed, such as the pug, to engage in tracking.

A dog's keen sense of smell helps a state trooper search for explosives at an airport.
Michael Grecco/Stock, Boston

Even in short-nosed breeds, however, the olfactory centre is relatively highly developed. It is arranged in folds in order to filter smells from the incoming air. Some rescue dogs are trained to follow a scent on the ground, and others are trained to scent the air. Both are able to distinguish one person from another even after a considerable passage of time. Hunting dogs—such as pointers, retrievers, and spaniels—are trained to scent birds and can distinguish one variety of bird from another.

The dog's sense of taste is poorly developed compared with that of humans. If forced to live on their own, dogs will eat almost anything without much discrimination.

Dogs possess an acute sense of hearing. Aboriginal breeds had large, erect and very mobile ears that enabled them to hear sounds from a great distance in any direction. Some modern breeds have better hearing than others, but they all can detect noises well beyond the range of the human ear. Dogs are able to register sounds of 35,000 vibrations per second (compared with 20,000 per second in humans), and they also can shut off their inner ear in order to filter out distracting sounds.

The eyesight of a dog is not as keen as its sense of smell, and it is generally thought that dogs have poor colour perception. Some breeds, such as the Saluki and the Afghan hound, were developed to chase game by sight over long distances, and these dogs can see well enough to detect any movement far on the horizon. Dogs can generally see better in poor light than humans but not as well in bright light. They have a wider field of vision than humans because their eyes are set further toward the sides of their heads, but they are not as adept at focusing on objects at close range or at judging distances. Dogs have a third eyelid, a membrane that protects the eyeball from irritants and is sometimes visible in front of the eye.

Dogs are sensitive to touch, the fifth sense, and use this sense to communicate with one another and with their human counterparts. Learning where to touch a dog is an important part in either stimulating or relaxing it and is useful in training a puppy or bonding with an adult dog.

Coats. There are three basic types of hair: short (as on a pointer or Doberman pinscher), medium (as on an Irish setter or Siberian husky), and long (as on a chow chow or Maltese). Within these categories there are also coarse and fine types of hair. Dogs come in a wide variety of colours, but in many breeds colour selection is an important consideration, as is the colour distribution on the dog.

Most dogs shed their coats seasonally. This is a natural occurrence that depends in large measure on the amount of available daylight. In the fall as days become shorter, a dog's coat will grow thicker and longer. In the spring the dog will begin to shed its coat, and it will take longer for the coat to grow in over the summer. Temperature influences the amount of body coat a dog grows. Dogs living in warm climates all year long rarely grow hair coats as thick as those living in colder areas, although this will affect the body coat and the amount of protective undercoat more than the topcoat or the length of furnishings on the belly, ears, and tail.

Grooming is an important part of touch to a dog and can be a pleasurable and relaxing means of relating to it. The dog's coat forms a barrier between the environment and the skin. Grooming the coat enhances the dog's beauty and well-being and gives the owner the chance to evaluate the general health of the dog.

Reproduction. *Sexual maturity.* There is some variation in the age at which dogs reach sexual maturity. Small breeds appear to mature faster than large ones, which usually cycle later. It is not uncommon for large-breed females to come into heat for the first time at more than 1 year of age, although 8 to 9 months is the norm. Dogs are sexually mature between 6 months and 1 year but are not socially mature until they are about 2 years of age. Females first cycle anywhere from 6 to 18 months of age and approximately twice a year thereafter. The only exception is the African basenji, which cycles annually, bearing one litter a year.

Female reproductive cycle

Reproductive cycle. The heat cycle of the female lasts from 18 to 21 days. The first stage is called proestrus. It begins with mild swelling of the vulva and a bloody discharge. This lasts for about 9 days, although it may vary by 2 or 3 days. During this phase the bitch may attract males, but she is not ready to be bred and will reject all advances. The next phase is the estrus. Usually the discharge decreases and becomes lighter, almost pink, in colour. The vulva becomes very enlarged and soft, and the bitch will be receptive to the male. This stage may last 3 or 4 days or as long as 7 to 11 days. The female may be receptive a day or two past the time when she would still be fertile. In order to be sure that the breeding is taking place at the optimum time, vaginal smears and blood tests can be done by a veterinarian beginning before estrus and through the estral phase.

At about the 14th day, or whenever estrus ends, the final, or luteal, stage of the cycle begins; this stage is called diestrus. The discharge becomes redder, the vulva returns to its normal size, and the bitch will no longer accept the male for mating. When all signs of discharge and swelling are absent, the heat is complete. The diestrus stage lasts 60 to 90 days (if no pregnancy has occurred) or until the bitch gives birth. She then enters anestrus, which is the time frame between the end of the last cycle and the beginning of the next proestrus.

Canine males are always fertile from the onset of their sexual adolescence, usually after six months of age. Larger-breed males may take a few months longer to become sexually mature. Males are usually promiscuous and are willing to mate with any available female.

Males produce far more sperm than is needed to impregnate the ova that are released during estrus. Small-breed bitches usually produce small litters. Two or 3 puppies in a breed such as a Yorkshire terrier is considered the norm. Large-breed litters can have as many as 10 or 12 puppies, although the normal bitch can suckle up to 8 at a time.

Gestation and whelping. The normal gestation period is 63 days from the time of conception. This may vary if the bitch has been bred two or three times or if the eggs are fertilized a day or two after the mating has taken place. Eggs remain fertile for about 48 hours. Sperm can live in the vaginal tract for several days. In order to determine if a bitch is pregnant, a veterinarian can manually palpate her abdomen at about 25 days after breeding. Ultrasound also can be done at that time. At about 40 days X rays will confirm pregnancy.

Most bitches whelp normally. However, the large-headed, short-bodied breeds and the toy breeds often must undergo cesarean sections in order to deliver live puppies.

Reproductive capacity. Both males and females are fertile well into their advanced age. It is generally considered best for the bitch to be bred for the first time upon maturity but not before her second or third heat cycle, depending on her age at the first. Because small breeds mature more quickly, they can be bred at an earlier age

than large breeds. A bitch will have less difficulty in conceiving and carrying a litter if she is bred before the age of five. As she becomes older, litter size generally decreases. After the age of seven, bitches are likely to have small litters and experience problems in delivering the puppies. Veterinarians feel that bitches generally should not be bred after that age.

Males can be bred as long as they are fertile, although with age the motility and quantity of sperm decrease.

BEHAVIOUR

The dog is a social creature. It prefers the company of people and of other dogs to living alone. It is, therefore, considered by animal behaviourists to be a pack animal. In this respect it is similar to its distant relative the wolf. As a result of millennia of selective breeding, the dog has been adapted to live with people. Seminal studies of dog behaviour conducted in the 1950s and '60s showed, however, that dogs raised without human contact at an early age retain their inherent instincts and prefer relationships with other dogs over associations with people.

Territory and range. Both dogs and wolves are territorial animals. Wolf packs, because of their need to hunt game, claim large territories as their own, whereas dogs claim their territories based on the limitations of their owners. Male wolves and dogs mark their territorial boundaries by urinating and rubbing their scent on the ground or on trees to warn other animals of their presence.

When on neutral ground, that which is not considered by either dogs or wolves to be their home territory, strangers greeting each other will go through formal rituals of sniffing, marking, tail wagging, and posturing. Unless they are claiming the same prey or are engaged in courting the same female, such interactions are usually terminated by each going its own way. Females will attack strangers in neutral territory to protect their young, however.

Types of barks

Barking. Both dogs and wolves have a repertoire of barks, growls, and howls that are identifiable among themselves and to humans who have studied their vocabulary. Dog owners can determine by certain sounds whether their pet is playful, warning of a stranger nearby, fearful, or hurt. One of the earliest signs that puppies are becoming social and independent creatures within the litter are the yips and barks that they make while playing with one another. Dogs, unlike wolves, will growl if cornered or fearful. Certain breeds of dogs, notably hounds, have been bred to enhance the howling instinct when they are on the trail of game. Some of the northern breeds, such as the Siberian husky, howl rather than bark. At the other end of the spectrum, the basenji does not bark but rather emits a yodeling sound when it is happy.

Behavioral development. Canine behaviour is a combination of instinct and environment. Dogs are born with certain innate characteristics that are evident from birth.

Puppy development

Puppies are born blind and deaf, totally dependent on the dam for warmth and nourishment. The dam will instinctively suckle and protect her young, often keeping other dogs and all but the most trusted people away from the whelping box. Between 10 and 14 days after birth, the eyes and ear canals open, and the puppies begin to move actively around their nest. As they grow, they become more curious and start to investigate their surroundings independently. The dam will begin to leave them alone briefly. During this phase they relate most intensely to their littermates and dam and may become unhappy at being removed from their familiar surroundings. This stage of development lasts about 20 days and is the first of four critical periods.

Beginning at three weeks of age, the most adventurous puppies will seek ways to get out of the whelping box and will start to investigate the larger world. At this age puppies are receptive to human contact, which is essential if they are to bond with people when they become adults. Dogs left alone from four weeks on will never reach their full potential as pets and will often become independent and more difficult to train than those accustomed to close human contact from an early age. At the same time, during the period between three and seven weeks, it is important that puppies socialize with their littermates and dam. This is when the dam weans her puppies, first by regurgitating some of her own food and then by not allowing her puppies to nurse as often as they would like. At about four weeks of age, puppies can be offered solid food in the form of a soft gruel.

Individual socialization of each puppy in a litter can begin at six weeks of age. This is when puppies begin to be more receptive to handling and attention.

The third critical period in a puppy's development is from 7 to 12 weeks. It has been shown in studies undertaken at various breeding kennels that this is the best age to form human-dog relationships. Attachments formed during this period will affect the attitude of the dog toward humans and toward its acceptance of direction and learning. During this period the pack instinct, which has played such an important role in the puppy's early development, can be transferred to humans. At this time environment becomes a vital part of the dog's education and training. This is when a human can most easily establish dominance over the dog, becoming the "leader of the pack." At this age a dog will accept a submissive role more readily than at any other time in its life. Learning comes most readily at this age. Puppies taught basic commands, even if they are not reinforced for several months, will remember them and respond if they are taught during this critical age.

The fourth critical stage in a puppy's development is between 12 and 16 weeks. At this age the puppy will declare its independence from its mother and will become increasingly daring in its forays from the familiar. Puppy training can begin during this period, and it is a time of rapid physical and mental growth. The permanent teeth begin to emerge at this time, which is often a painful and distractive process. Puppies need to chew during this period, and, if they are not provided with appropriate teething toys, they will use any available hard object, such as furniture. Puppies at this age may be less willing to cooperate or respond to new commands.

A dog's personality continues to develop during its entire maturing process and will undergo radical changes while the dog matures sexually and physically. Dogs mature sexually earlier than they do emotionally. Their personalities develop more slowly than their bodies, much like humans but unlike wolves, whose personalities and sexuality develop more harmoniously.

At about seven or eight months many puppies tend to go through a period of anxiety. They are insecure, frightened of strangers, and will appear timid. If this is not an inherited trait, it will disappear within a few months. If it is inherited, that condition will remain and may become accentuated with time.

Breed-specific behaviour. There are distinctive breed-typical personalities that have been developed through generations of selection for certain traits. By roughly grouping dogs according to the work they were bred to do, it is possible to determine the type of temperament a dog might have at maturity. Differences in breed personalities can be seen at an early age. Sporting dogs will generally be adventurous, following their noses wherever scents lead them, but will respond enthusiastically to calls from familiar humans. Hounds generally tend to be more aloof and independent, inclined to scout the territory on their own and follow a scent or a movement; they are not as interested in human interaction as the bird dogs are.

Working and herding dogs have more business-like dispositions. They tend to evaluate situations and set about their tasks. Collie puppies have been known to herd children, ducklings, or each other in an instinctive manifestation of their birthright. Guarding dogs tend to be protective of their territories, even at an early age. Such dogs as the Maremma or the kuvasz, which are bred to guard flocks, are placed with the sheep from the time they are puppies in order to reinforce their basic protective instincts. Collies and Akitas are known for their strong sense of loyalty. Terriers, bred to chase and catch rodents, have a tendency to be extremely active, lively, and feisty as puppies, traits that continue into adulthood. Newfoundlands are renowned for lifesaving instincts.

Breed specificity also affects how well dogs adapt to new surroundings or to new owners. Such things cannot be

taught to dogs. They are innate—part of a dog's instinctive behaviour—and are often breed-specific, although mixed breeds have been known for unique instincts as well.

DOGS AS PETS

The companionship between humans and dogs is not a new phenomenon. However, in modern society most dogs are owned as pets, not because of the work they were bred to do. Many breeds, such as the toy dogs, were developed precisely to be pets. All of the diverse breeds and mixed breeds have unique traits and appeal to different kinds of people.

Acquiring a dog is a major decision, because the dog becomes totally dependent on its owner for its care and welfare. This responsibility continues throughout the life of the dog. Thus, the initial decision should be based on a serious consideration of whether one's lifestyle truly lends itself to owning a dog—that is, whether a dog would be an asset rather than a liability.

Selecting a breed

Selection. The next consideration is the selection of a particular type of dog. Many people want a purebred dog because they like the appearance or the personality, and they are assured that the puppy they buy will grow up to look like the breed it represents. Others find that a mixed breed will do just as well, and there are many shelters, humane societies, and rescue groups that harbour dogs in need of homes.

No matter what kind of dog a person chooses, it is essential that it be a healthy animal. When evaluating a puppy or an adult dog, several features will help determine the physical condition of the animal. The dog should appear friendly and outgoing. Puppies in particular should exhibit curiosity and a tail-wagging enthusiasm. They should not hang back or appear timid or frightened. Eyes should be bright and shiny with no discharge, and the inner eyelids ought to be smooth and pink. Ears should be clean-smelling and free of debris. Gums must be pink and firm, except in the case of chow chows and shar-peis, whose gums and tongue are black. The skin should feel warm and dry to the touch. Clammy skin or the presence of reddened patches, crusts, scales, or parasites are indicative of problems that could be both external and internal. The hair coat ought to be clean and sweet-smelling. The dog should be in good form and build, but not obese or so thin that the ribs and hipbones show.

People buying purebred dogs should know the distinctive characteristics of the breed they have chosen, so that they can ask the breeder proper questions and have some means of evaluating the quality of the dog they are purchasing. Many purebred dogs have hidden genetic problems of which good breeders are aware. Many of these problems can be controlled by careful breeding, but the purchaser must know—through reading about the breed and talking to fanciers—what questions to ask. Mixed-breed dogs also can have hidden genetic problems, but there is no way to determine what they might be or whether they will eventually affect the dog in an adverse manner.

Great strides are being made in veterinary research to identify genetic defects and thereby assist breeders to select the best breeding stock. By eliminating from their gene pool those dogs with genetic abnormalities, breeders can help ensure that the breed remains healthy and viable.

Nutritional requirements

Nutrition and growth. Puppies need three basic things in order to thrive: good nutrition, warmth, and companionship. Puppies need to eat three or four times a day from the time they are weaned until they are about six months old. Thereafter they can be fed twice a day until maturity and once daily after that. However, many dog owners, especially those with large breeds, feed twice a day throughout the dog's life (this does not mean feeding more than the required daily amount, but it is a more balanced method of feeding).

Puppies need twice an adult dog's maintenance requirements of energy and nutrients for proper growth from the time they are weaned until they reach about half of their expected mature weight. There should be steady growth on a weekly basis, but there should be no excess fat around the abdomen. Puppies grow best if they remain at a suitable weight without becoming obese. Overweight puppies are candidates for crippling bone diseases if they are too heavy during the critical growing months. On the other hand, feeding too little will result in poor growth and lack of energy.

Adult dogs burn fewer calories than do puppies or young and active adults. Therefore, they need to eat less in order to maintain optimum weight and activity.

Dogs that work require extra nutrients. For instance, sled dogs need to be fed a diet that is much higher in calories, one with a ratio of fat, protein, and carbohydrates very different from the diet of more sedentary dogs. Owners may have to experiment with different types of food to determine which are best suited to their dogs.

There are three basic types of commercially produced dog foods: canned, dry, and semimoist. Predominant ingredients of most of these include corn, wheat, barley, rice, or soy meal, in combination or alone. Commercial dog foods also include a meat such as beef, lamb, chicken, or liver, or meat by-products. It is important to read the labels to determine the proportions of each and the amounts of proteins, carbohydrates, fats, and vitamins and minerals contained.

Sleep is almost as important as nutrition for puppies. A warm, quiet place for them to rest is essential for normal growth. Puppies will usually play vigorously and then suddenly fall asleep. Their need for sleep decreases as they grow into adulthood, but dogs spend a great deal of their time sleeping when they are not stimulated to activity.

Exercise requirements

All dogs need exercise, some more than others. Achieving good health and sound temperament demands that dogs be given the opportunity for regular stimulating exercise. Puppies should be allowed to run at will without restraint and without being pushed beyond their limits. As dogs mature, jogging or walking on a lead can be introduced, but any forced exercise should be withheld until the dog is fully grown. The most common cause of a dog's destructive behaviour in the house is lack of exercise. Behavioral problems such as tail chasing, chewing, and excessive barking and whining can in most cases be traced to confinement for long periods of time without respite. The ability to provide adequate exercise is one of the most important considerations that prospective dog owners must face before acquiring a puppy. Exercise, however, does not mean allowing the dog to run at large. Dogs ought to be supervised at all times when outside: they either should be accompanied by owners using a lead or have a securely fenced area in which to play.

The term companion animal means that dogs need company. They are happiest when allowed to be an integral part of the household. Puppies thrive and learn when they are included in the household routine at an early age. Training becomes easier when the unique bond between human and dog is strengthened from the beginning.

Training. Puppies learn by watching, but their instincts guide how readily they will learn certain basic requirements. A dog bred to guard the home will be less likely to run off following a scent than a bird dog bred to hunt game. On the other hand, a guarding breed will need direction concerning who is "acceptable" and who is not, whereas a retriever will befriend everyone. Knowledge of what a dog was bred to do is useful when trying to train it to be an acceptable companion.

There are many theories about how to train a dog to be a happy and willing companion, but certain principles apply to all methods. The dog must understand what is expected. It has to be praised for doing well. Punishment for an infraction should be immediate and appropriate to the act. The dog must be able to associate the punishment with the crime. Consistency and kindness bring the best results in training. Most dogs will accept domination readily, but there are some, usually males, who will challenge that authority. This is dangerous behaviour and must be stopped at an early age. Good training must be sensible, and commands should be enforceable.

Other maintenance concerns. Dogs need regular care from the time they are born. In addition to a balanced diet, grooming is an important part of maintaining good health. Care of the ears, coat, and nails on a weekly basis gives owners an opportunity to examine their pets and to

spot any potential illness. Ears should be cleaned regularly and nails kept trimmed. Brushing should be part of a dog's weekly or even daily routine. Dogs with long or thick coats will need more frequent brushing than shorthaired varieties in order to loosen dead hair and prevent skin irritations or infection.

Regular veterinary care is important to a dog's health. Puppies usually are vaccinated against the most virulent diseases, starting at six weeks of age. A series of three or four vaccinations against distemper, hepatitis, parainfluenza, leptospirosis, and parvovirus are given three weeks apart. At three months of age puppies can be inoculated against rabies. Booster vaccinations are given annually thereafter, except for rabies shots, which may be administered every two or three years, depending on the region. Routine vaccination procedures have succeeded in reducing, and in some areas eliminating, diseases that formerly killed half of all puppies born.

In many areas veterinarians recommend that dogs be tested annually for heartworm disease and be given a preventative. This should be administered throughout the dog's life as long as it resides in a region where and when this parasite is prevalent.

Ailments. Fleas and ticks are sources of irritation and disease in every climate of the world (with the possible exception of the Arctic). Regular bathing and grooming helps to keep these and other external parasites under control. Treatment of the animal and its environment are essential to eliminate these pests. In some areas this is a yearlong process, whereas in other climates it is a seasonal problem.

Common ailments

Internal parasites are a common cause of sickness, especially in puppies. There are many kinds of worms that invade the intestinal tract, resulting in listlessness, loss of blood and subsequent anemia, poor hair coat, and occasionally death. Many of these parasites are found in dirt and are ingested or get into the bloodstream through the skin of the dog. Effective veterinary remedies are available for the animal, but it is important to determine through fecal examination or blood tests exactly what type of parasite is present. Puppies should be examined about every three months, and adults need to be examined annually.

Dogs are susceptible to many of the same illnesses that afflict humans. Cancer, respiratory ailments, allergies, arthritis, and certain forms of heart disease are all found in dogs. Some illnesses have a breed predilection, whereas others occur in all pure and mixed breeds. Large- and giant-breed dogs, such as Irish setters, St. Bernards, bloodhounds, and Great Danes, are prone to a condition known as gastric dilatation volvulus (GDV). This disease causes the stomach to twist in the abdominal cavity, cutting off the blood supply and filling the stomach with gas. GDV is always a medical emergency and must be treated as soon as the first symptoms appear. Early warnings may be restlessness, unsuccessful attempts to vomit or defecate, swelling of the abdomen, or distention of the rib cage.

Large breeds also are at risk for an orthopedic problem in which the hip joint does not develop properly. This is called hip dysplasia and is considered to be a polygenetic condition. It is a progressive disease in which the malformation of the hipbones causes arthritic changes, lameness, and pain. Some breeds are also at risk of developing elbow dysplasia and other problems of the bones and joints. Dogs built with long, low bodies, such as dachshunds, often develop spinal injuries or malformations of the spinal column.

Heart problems

Dogs do not suffer from high cholesterol or from the life-threatening circulatory illnesses that afflict humans, but certain breeds are predisposed to malformations of the heart muscle and valves. Some of these are surgically correctable, while others are not. In addition, heartworm and other parasites may affect the heart and circulatory system.

Dogs are as much at risk of contracting cancers as people are. The treatment is often the same. Cancers most often seen in dogs involve osteosarcomas, mammary tumours, and lymphomas. Veterinary research is at the forefront of the development of new treatments for cancers in the hope that new methods for combating them in humans will be found in the process.

Eye diseases, many of which are hereditary, also are found in dogs. Dogs are subject to cataracts, glaucoma, and retinal diseases, all of which can cause blindness. Treatments in dogs are not as successful as in humans, but dogs appear to adjust to vision loss very well as long as they are kept in familiar surroundings. Their keen sense of smell helps them to get around, although they must be protected from sudden falls and unforeseen dangers. Many canine ocular problems of a hereditary origin are difficult to eradicate because they do not appear in some breeds until the dogs are five or six years old. Nonetheless, genetic research to identify dogs that are carriers or that will develop eye problems has made significant strides since it began in the 1970s.

Breeds with large, protruding eyes, such as the Pekingese or the pug, are susceptible to eye irritations and corneal lacerations. These must be attended to promptly to avoid serious damage to the eye.

Dogs with dropped ears—the basset hound is an extreme example—are prone to diseases of the ear canal. Moisture becomes trapped in the ear, producing yeast infections. Such parasites as ear mites thrive in the ear canal, causing a dark, malodorous exudate. Frequently, the dog is uncomfortable and scratches the ears or rubs the ears along the ground or on the furniture. Most ear problems can be cured with proper medication. If problems are left unattended, the ear canal will develop ulcerations that are painful and difficult to treat.

THE BREEDS

There are approximately 400 separate breeds of purebred dogs worldwide. A purebred dog is considered to be one whose genealogy is traceable for three generations within the same breed. National registries, such as the American Kennel Club (AKC) in the United States, the Canadian Kennel Club, the Kennel Club of England, and the Australian National Kennel Council, maintain pedigrees and stud books on every dog in every breed registered in their respective countries. The Foxhound Kennel Stud Book, published in England in 1844, was one of the earliest registries. Other countries also have systems for registering purebred dogs. The AKC represents an enrollment of more than 36 million since its inception in 1884, and it registers approximately 1.25 million new dogs each year.

In the 1800s those interested in the sport of dogs developed a system for classifying breeds according to their functions. The British classification, established in 1873 and revised periodically by the Kennel Club of England, set the standard that other countries have followed, with some modifications. British, Canadian, and American classifications are basically the same, although some of the terminology is different. For example, Sporting dogs in the United States are Gundogs in England. Utility dogs in England are Non-Sporting dogs in the United States and Canada. Not all countries recognize every breed.

Early classification systems

The United States recognizes seven classifications, called groups (encompassing more than 130 breeds), whereas the English and Canadians have six groups (the American system divides the Working group into two groups: Working dogs and Herding dogs). The groups recognized by the AKC are:

Sporting dogs. These are dogs that scent and either point, flush, or retrieve birds on land and in water. They are the pointers, retrievers, setters, spaniels, and others, such as the vizsla and the Weimaraner.

Hounds. These also are hunting dogs but much more various than the Sporting dogs. There are scent hounds and sight hounds. They are a diverse group, ranging from the low-slung dachshund to the fleet-footed greyhound. However, they all are dedicated to the tasks for which they were bred, whether coursing over rough terrain in search of gazelles, such as the Afghan hound or the Saluki, or going to ground after badgers, like the dachshund. Hounds such as beagles, basset hounds, harriers, foxhounds, and coonhounds run in packs, while others, such as Afghan hounds, borzois, pharaoh hounds, and Salukis, course alone. The Hound group also includes the Petit Basset Griffon Vendéen, the otterhound, the Rhodesian ridgeback, which was bred to hunt lions in Africa, and

the bloodhound, best known for its remarkable ability to track. The Irish wolfhound, Scottish deerhound, basenji, whippet, and Norwegian elkhound are also in this group. In Canada, drevers belong to the Hound group as well, and in England the Grand Basset Griffon Vendéen is included.

Terriers. The Terrier group consists of both big and small dogs, but members of this group more than any other share a common ancestry and similar behavioral traits. Terriers were bred to rid barns and stables of vermin, to dig out unwanted burrowing rodents, and to make themselves generally useful around the stable. Terriers were used in the "poor man's recreation" of rat killing, especially in England where most of these breeds originated. Upper classes used terriers in foxhunting. They also were bred to fight each other in pits—hence the name pit bulls. During the late 1900s, dogfighting was outlawed in most states and countries of the Western world, and these dogs were thereafter bred for a friendly temperament rather than for aggressiveness.

Terrier characteristics

Terriers, because they had to fit in burrows and dig underground, were bred to stay relatively small, although large breeds are not uncommon. Their coats are usu-

*All breeds are recognized by the American Kennel Club unless otherwise noted. Height and weight measurements in boldface represent official standards of the AKC. All other measurements are average ranges for both dogs and bitches. Countries listed are those most closely associated with the breed. †Only recognized by the Canadian Kennel Club. ‡Only recognized by the Kennel Club of England.

ally rough and wiry for protection and require minimum maintenance. Unlike hounds or sporting dogs, which only found or chased their quarry, terriers were often required to make the actual kill as well, giving them a more pugnacious temperament than their size might suggest. They are usually lean with long heads, square jaws, and deep-set eyes. However, as with most breeds, form follows function: terriers that work underground have shorter legs, while terriers bred to work aboveground have squarer proportions. Terriers are active and vocal, naturally inclined to chase and confront.

The small terriers, which were often carried on horseback during foxhunts, were bred to be put to the ground. These dogs have very specific origins. In general, their names reflect the locale where the breed first took shape under the guidance of a small group of dedicated breeders. They are the Australian, Bedlington, border, cairn, Dandie Dinmont, Lakeland, Manchester, miniature schnauzer (of German origin), Norwich, Norfolk, Scottish, Sealyham, Skye, Welsh, and West Highland white. The larger terriers include the Airedale, Irish, Kerry blue, and soft-coated wheaten. In Canada, Lhasa apsos are part of this group. Britain claims the Parson Jack Russell and the Glen of Imaal terriers, both of which are found in the United States, although the Glen of Imaal is not recognized by the AKC.

Working dogs. This group of dogs was bred to serve humans in very practical and specific ways. They are the dogs most often associated with guarding, leading, guiding, protecting, pulling, or saving lives. Working dogs range in size from medium to large, but all are robust with sturdy and muscular builds. Working dogs are characterized by strength and alertness, intelligence and loyalty.

Among the breeds most often associated with guarding home, person, or property are the Akita, boxer, bullmastiff, Doberman pinscher, giant schnauzer, Great Dane, mastiff, Rottweiler, and standard schnauzer. Dogs bred to guard livestock are the Great Pyrenees, komondor, and kuvasz. In England, Pyrenean mountain dogs are recognized in this group, as are all the herding dogs, and, in Canada, Eskimo dogs are included. Also in the Working group are those dogs bred to pull, haul, and rescue. These include the Alaskan Malamute and Siberian husky, the Samoyed, the Bernese mountain dog, the Portuguese water dog, the Newfoundland, and the St. Bernard. Poodles of the three varieties (standard, miniature, and toy) are part of this group in England, as are several other breeds found in the Non-Sporting group in the United States.

Herding dogs. The Herding breeds are livestock-oriented, although they are versatile in protecting and serving humans in other ways. Herding breeds are intelligent and lively, making fine family pets or obedience competitors. Dogs were first used to assist sheepherders in the 1570s, but other varieties were bred for different herding tasks. Herding breeds are quick and agile, able to work on any terrain, and well-suited for short bursts of high speed. These dogs, even the compact breeds, are strong and muscular, possessing proud carriage of head and neck. Herding dogs perceive even the slightest hand signals and whistle commands to move a flock or seek out strays.

Some Herding breeds drive the flock by barking, or circling. Others, such as the Welsh Corgi, nip at the heels of the flock to drove them. The Border Collie confronts the flock with a silent stare, a form of intimidation which also proves effective.

Uses for herding dogs

Herding dogs serve other functions. These breeds are excellent guards, used in the military and law enforcement, or for personal protection. Herding dogs are among those with the closest relationship to humans.

Toys. The Toy group is composed of those canines that were bred specifically to be companion animals. They were developed to be small, portable, and good-natured, the sort of dog that ladies of the court could carry with them. These dogs were largely pampered and treasured by aristocracy around the world. Several of these breeds come from ancient lineage. The Pekingese and the Japanese Chin were owned by royalty. No one else was permitted to own one of these breeds. They were carefully bred and nurtured, and until the mid-20th century they were not allowed to be exported out of their countries of origin. In England the cavalier King Charles spaniel, a bred-down version of a sporting spaniel, was the favourite pet of many royal families. Toy poodles also belong to this group.

The miniature pinscher resembles the Doberman pinscher but in fact is of quite different legacy. This perky little dog has a particularly distinctive gait, found in no

(Left) A Labrador retriever fetches game from the water; (top right) an Australian shepherd maneuvers a flock of sheep; (bottom right) Siberian huskies and Eskimo dogs pull an Inuit sled.

other breed. Its standard calls for a hackney gait, such as that found in carriage horses. Other members of the Toy group are equally individual in their looks and personalities, making this the most diverse group. They make ideal apartment or small-house pets and are found ranging from hairless (the Chinese crested) to the profusely coated Pekingese or Shih tzu. In general, however, Toy breeds are alert and vigorous dogs. They are fine-boned and well-balanced, often considered graceful animals.

Non-Sporting dogs. The Non-Sporting group is a catchall category for those breeds that do not strictly fit into any other group. (Arguments could be made for assigning some of these breeds to other groups. The Dalmatian, for instance, could be a Working dog, as it is in England.) This group includes the appealing bichon frise, the bulldog, the poodles (standard and miniature), and the Chinese shar-pei. All have unique histories, many quite ancient. Other Asian representatives are the Tibetan spaniel and the Tibetan terrier—neither of which are true spaniels or terriers—the chow chow, and the Lhasa apso. Non-Sporting is also the category for the Finnish spitz, the Keeshond, the French bulldog, and the schipperke. All the Non-Sporting breeds are of small to medium build with sturdy and balanced frames, often squarelike. The chow chow, French bulldog, and the Dalmatian are among the more muscular breeds in this group. In general, Non-Sporting dogs are alert and lively.

There is no comparable classification in Britain, although all these breeds, except for the Boston terrier, are found in other groups. The Boston terrier (not a true terrier although it once contained terrier blood) is one of the few native American dogs. (The others are the Alaskan Malamute, the beagle, the American foxhound, the Chesapeake Bay retriever, and the American cocker spaniel, all found in other groups.)

Breed standards. Purebred dogs are distinguished from mixed-breed animals because their genetic structure allows them to reproduce themselves generation after generation. Every breed that is registered with a national registry, such as the American Kennel Club or the Kennel Club of England, must have a "standard" for that breed. The standard is the blueprint by which a breed is evaluated. It describes the characteristics that make a particular breed unique. Standards were developed by fanciers who wanted to perpetuate a particular line or strain and who formed associations to foster certain breeds. It is the goal of most purebred-dog fanciers to breed dogs that best represent the ideal qualities for the breed as described by the standard. Standards outline requirements for physical traits and behavioral or "personality" traits.

Breed evaluation standards

RELATED CANIDS

The evolutionary process that brought about the domestication of the wild canid also created many other types of canids that have remained similar to dogs in genetic structure but with marked differences.

Wolves. The modern dog appears to be closely related to its most common ancestor, the wolf. The *Canis lupus* species includes more than 30 subspecies found in different parts of the world, some of which are now extinct. The subspecies vary greatly in size and colour, with the largest (averaging 95 to 100 pounds [43 to 45 kilograms]) found in the Arctic regions and the smallest (averaging 30 to 35 pounds) being the Texas red wolf.

The most striking similarities between the dog and the wolf are their instinctive behaviours of play, dominance and submission, scent marking, and the females' care for their young. Wolves are much more like dogs than like either coyotes or foxes in temperament and manners. Wolves appear to be instinctively more social than any of the other wild canids, thus lending themselves to interaction with humans in relationships beneficial to both. Wolves and dogs will mate willingly, as will dogs and coyotes. There are differences, however. The wolf matures more slowly than the dog. It reaches sexual maturity at about the age of two or three, at the same time that it achieves social maturity. A male wolf will not challenge the leaders of the pack until it is both physically and behaviorally mature. The female wolf cycles annually.

Coyotes. The coyote, *Canis latrans*, is a wide-ranging animal similar to wolves in some ways but different in others. Coyotes are light-boned, rangier in body with longer, narrower jaws and smaller ears and feet. They are thought to be the most intelligent of the wild canids because they have been able to survive and thrive despite human efforts to exterminate them for hundreds of years. Coyotes can weigh between 25 and 60 pounds and are usually gray to light tan in colour, depending on the region. There are more than a dozen subspecies of coyotes ranging throughout North and Central America. Coyotes tend to live in smaller groups than wolves, sometimes leading solitary lives until they reach sexual maturity at about two years, and they mate for life.

Foxes. Perhaps the most distinctive feature of the fox family, as compared with wolves and coyotes, is the eyes. They are yellow with elliptical pupils. All other canids, including dogs, have round pupils. Foxes are monogamous and do not live in packs. They are among the smaller species of canids, ranging from only 10 to 15 pounds. The more common foxes include the red fox, the gray fox, and the Arctic fox, which is valued for its fur.

There are several varieties of large-eared foxes, most of which are native to Africa and all of which are in danger of extinction because they are widely hunted and their habitat is being overbuilt by human settlements.

The smallest canid is the fennec. It weighs about three pounds, and its ears are about one-fourth of its body size. This endangered species is native to the desert areas of North Africa and the Arabian and Sinai peninsulas.

Jackals. There has been some disagreement over the years about whether the jackal is a true canid, but the four known varieties are now thought to be part of the same genus. Jackals are native from southeastern Europe into southern Asia, India, and Africa. The best-known variety is the golden jackal, which is a shimmery rust-gold in colour. Jackals are fleet-footed hunters, but they also eat insects and are best known as scavengers after larger animals, such as lions. The other varieties are the crafty black-backed jackal, the shy side-striped jackal, and the rare Abyssinian jackal.

Other wild canids. There are several different species of wild canids in South America. They fall somewhere between the fox and the wolf but are neither. One of the most interesting is the maned wolf, found in southern South America. The maned wolf is a fairly large animal, weighing about 50 pounds. It is very long-legged for its body length and is reddish brown in colour with a black ruff of hair around the neck. Its muzzle and feet are dark, and it has a white patch on the throat and a white plume on its tail.

In contrast to the maned wolf is the lowly Guiana bush dog. This short-legged, furry creature looks like a beaver but has longer legs and is an excellent swimmer and diver. It lives in packs of about 12 in the jungles of South America and is rarely seen by humans.

The most primitive member of the canid family is the Japanese raccoon dog. It is the only one that hibernates, moves into winter and summer ranges, and looks like a cross between a raccoon—because of its colour and markings—and a fuzzy fox. It has a heavy body (weighing a maximum of about 15 pounds) and is bred domestically for its fur, which is called tanuki.

The raccoon dog

One of the most important wild dogs is the dingo. It is believed that the dingo arrived in Australia between 9,000 and 15,000 years ago, but how it got there remains uncertain. Some scientists believe that the dingo is a small wolf, but others believe it is a true dog, much closer in behaviour to the domesticated dog than to the wolf. It has all the characteristics of a canine, with the exception that females cycle annually, like most of the other wild canids. Dingoes hunt in packs but may be found either alone or in a social group. Because dingoes are feared as livestock killers, considerable effort has been made to eliminate them, as with coyotes, although the latter have a higher survival rate. Dingoes are rarely seen in Australia now outside of zoos, and preservation efforts are being made to protect them in the wild.

Finally, the dhole, also called the Asiatic red dog, has

the widest range of any of the wild canids. It is found throughout most of the Asian mainland as high as the Himalayas and as low as the tropical islands of Borneo. It is reddish brown in colour, and on certain parts of the body the hair is gray or dark-tinged. The dhole is short-haired with a sturdy body and a pointed, felinelike face. Other varieties of the dhole family resemble short-coated wolves or Siberian-type dogs. Dholes hunt in packs; they do not bark or growl but may howl or whimper as a means of communication. Several of the canid species do not bark, but all are capable of sounding alarms or signaling to each other through vocalization.

Many of the wild dog species can be found only in captivity now. Through the efforts of zoologists, humans can maintain the link between these animals and the domestic dog that has thrived under human protection.

A distinction must be made between wild dogs and feral dogs. Feral dogs are domesticated dogs that have escaped to the wild, either through accident or neglect, and have reverted in the natural state to some of the characteristics inherent in all canids. They hunt or scavenge, run in packs, and become difficult to manage and train. They may become predators without the innate fear of humans that most wild canids have. Feral dogs may be found in cities or in the country and may be a reservoir of disease and a danger to domestic animals and people. (C.B.V.)

BIBLIOGRAPHY. THE AMERICAN KENNEL CLUB, *The Complete Dog Book*, 18th ed. (1992), comprehensively illustrates every breed that is registerable in the AKC stud book and includes a chapter on health care and puppy management. DAVID TAYLOR and CONNIE VANACORE, *The Ultimate Dog Book* (1990), is an illustrated overview of most of the breeds registered in the United States and Great Britain, with brief histories and descriptions of each.

FERNAND MÉRY, *The Life, History, and Magic of the Dog* (1970; originally published in French, 1968), traces the beginnings of the domestication of the dog and recites legends concerning the dog and its ancestors throughout the world. STANLEY J. OLSEN, *Origins of the Domestic Dog* (1985), is an anthropological study of fossils, primarily in the United States. MAXWELL RIDDLE, *The Wild Dogs in Life and Legend* (1979), describes many wild canids that exist in different parts of the world and relates the stories natives tell about them.

A vastly important contribution to the understanding of canine behaviour is JOHN PAUL SCOTT and JOHN L. FULLER, *Genetics and the Social Behavior of the Dog* (1965, reissued as *Dog Behavior: The Genetic Basis*, 1974), describing the genetic structure of personality based on original research by the authors. The foundational work describing the development of personality in puppies is CLARENCE J. PFAFFENBERGER, *The New Knowledge of Dog Behavior* (1963), based on research done by Scott and Fuller in the 1950s. JACK VOLHARD and MELISSA BARTLETT, *What All Good Dogs Should Know* (1991), is a basic primer for obedience training. CAROL LEA BENJAMIN, *Mother Knows Best: The Natural Way to Train Your Dog* (1985), uses a commonsense approach to teaching basic manners and solving problems.

WILLIAM J. KAY and ELIZABETH RANDOLPH, *The Complete Book of Dog Health* (1985), gives detailed descriptions of the major organ systems of the dog and describes common ailments and symptoms that dog owners can identify. HAROLD R. SPIRA, *Canine Terminology* (1982), definitively describes canine anatomy, illustrated from nose to tail. TERRI MCGINNIS, *The Well Dog Book* (1991), is a basic veterinary manual for dog owners. Also helpful is MALCOLM B. WILLIS, *Practical Genetics for Dog Breeders* (1992), which studies the genetic structure of the dog, including anatomy, coat colour, and breed differentiation. (C.B.V.)

Dostoyevsky

Fyodor Mikhaylovich Dostoyevsky, usually regarded as one of the finest novelists who ever lived, exercised an immense influence on 20th-century fiction and thought. Literary modernism, existentialism, and various schools of psychology, theology, and literary criticism have been profoundly shaped by Dostoyevsky's ideas. His works are often called prophetic because he so accurately predicted how Russia's revolutionaries would behave if they came to power. In his time he was also renowned for his activity as a journalist.

Major works and their characteristics. Dostoyevsky is best known for his novella *Notes from the Underground* and for four long novels, *Crime and Punishment, The Idiot, The Possessed* (also and more accurately known as *The Demons* and *The Devils*), and *The Brothers Karamazov*. Each of these works is famous for its psychological profundity, and, indeed, Dostoyevsky is commonly regarded as one of the greatest psychologists in the history of literature. He specialized in the analysis of pathological states of mind that lead to insanity, murder, and suicide and in the exploration of the emotions of humiliation, self-destruction, tyrannical domination, and murderous rage. These major works are also renowned as great "novels of ideas" that treat timeless and timely issues in philosophy and politics. Psychology and philosophy are closely linked in Dostoyevsky's portrayals of intellectuals, who "feel ideas" in the depths of their souls. Finally, these novels broke new ground with their experiments in literary form.

Dostoyevsky, 1880.

Family background

Early life. Dostoyevsky was born in Moscow on Oct. 30 (Nov. 11, New Style), 1821. His father, a retired military surgeon, served as a doctor at the Mariinsky Hospital for the Poor. Though a devoted parent, Dostoyevsky's father was a stern, suspicious, and rigid man. By contrast, his mother, a cultured woman from a merchant family, was kindly and indulgent. Dostoyevsky's lifelong attachment to religion began with the old-fashioned piety of his family, so different from the fashionable skepticism of the gentry.

Dostoyevsky's father bought an estate in 1831, and so young Fyodor spent the summer months in the country. Until 1833 Dostoyevsky was educated at home, before being sent to a day school and then to a boarding school. Dostoyevsky's mother died in 1837, and his father's death came suddenly in 1839. At the time, Dostoyevsky was a student in the Academy of Military Engineering in St. Petersburg, a career as a military engineer having been marked out for him by his father.

Dostoyevsky was evidently unsuited for such an occupation. Entranced with literature from an early age, he was drawn to Romantic and Gothic fiction, especially the works of Sir Walter Scott, Ann Radcliffe, Nikolay Karamzin, Friedrich Schiller, and Aleksandr Pushkin. Not long after completing his degree (1843) and becoming a sublieutenant, Dostoyevsky resigned his commission to commence a hazardous career as a writer living off his pen.

Early works. Dostoyevsky did not have to toil long in obscurity. No sooner had he written his first novella, *Bednyye lyudi* (1846; *Poor Folk*), than he was hailed as the great new talent of Russian literature by the most influential critic of his day, the "furious" Vissarion Belinsky.

Poor Folk

Poor Folk is cast in the then already anachronistic form of an epistolary novel. Makar Devushkin, a poor copying clerk who can afford to live only in a corner of a dirty kitchen, exchanges letters with a young and poor girl, Varvara Dobrosyolova. Her letters reveal that she has already been procured once for a wealthy and worthless man, whom, at the end of the novel, she agrees to marry. The novel is remarkable for its descriptions of the psychological (rather than just material) effects of poverty. Dostoyevsky transformed the techniques Nikolay Gogol used in "The Overcoat," the celebrated story of a poor copying clerk. Whereas Gogol's thoroughly comic hero utterly lacks self-awareness, Dostoyevsky's self-conscious hero suffers agonies of humiliation. In one famous scene, Devushkin reads Gogol's story and is offended by it.

In the next few years Dostoyevsky published a number of stories, including "Belyye nochi" ("White Nights"), which depicts the mentality of a dreamer, and a novella, *Dvoynik* (1846; *The Double*), a study in schizophrenia. The hero of this novella, Golyadkin, begets a double of himself, who mocks him and usurps his place. Dostoyevsky boldly narrates the story through one of the voices that sounds within Golyadkin's psyche so that the story reads as if it were a taunt addressed directly to its unfortunate hero.

Although Dostoyevsky was at first lionized, his excruciating shyness and touchy vanity provoked hostility among the members of Belinsky's circle. Nekrasov and Turgenev circulated a satiric poem in which the young writer was called, like Don Quixote, "The Knight of the Doleful Countenance"; years later, Dostoyevsky paid Turgenev back with a devastating parody of him in his novel *The Possessed.* Belinsky himself gradually became disappointed with Dostoyevsky's preference for psychology over social issues.

Political activity and arrest. In 1847 Dostoyevsky began to participate in the Petrashevsky Circle, a group of intellectuals who discussed utopian socialism. He eventually joined a related, secret group devoted to revolution and illegal propaganda. It appears that Dostoyevsky did not sympathize (as others did) with egalitarian communism and terrorism but was motivated by his strong disapproval of serfdom. On April 23, 1849, he and the other members of the Petrashevsky Circle were arrested. Dostoyevsky spent eight months in prison until, on December 22, the prisoners were led without warning to the Semyonovsky Square. There a sentence of death by firing squad was pronounced, last rites were offered, and three prisoners were led out to be shot first. At the last possible moment, the guns were lowered and a messenger arrived with the information that the tsar had deigned to spare their lives. The mock-execution ceremony was in fact part of the punishment.

Mock-execution ceremony

Dostoyevsky passed several minutes in the full conviction that he was about to die, and in his novels characters repeatedly imagine the state of mind of a man approaching execution. The hero of *The Idiot,* Prince Myshkin, offers several extended descriptions of this sort, which

readers knew carried special authority because the author of the novel had gone through the terrible experience. The mock execution led Dostoyevsky to appreciate the very process of life as an incomparable gift and, in contrast to the prevailing determinist and materialist thinking of the intelligentsia, to value freedom, integrity, and individual responsibility all the more strongly.

Instead of being executed, Dostoyevsky was sentenced to four years in a Siberian prison labour camp, to be followed by an indefinite term as a soldier. After his return to Russia 10 years later, he wrote a novel based on his prison camp experiences, *Zapiski iz myortvogo doma* (1861–62; *The House of the Dead*). Gone was the tinge of Romanticism present in his early fiction. The novel, which was to initiate the Russian tradition of prison camp literature, describes the horrors that Dostoyevsky actually witnessed: the brutality of the guards who enjoyed cruelty for its own sake, the evil of criminals who could enjoy murdering children, and the existence of decent souls amid filth and degradation. Tolstoy considered it Dostoyevsky's masterpiece. Above all, *The House of the Dead* illustrates that, more than anything else, it is the need for individual freedom that makes us human. This conviction was to bring Dostoyevsky into direct conflict with the radical determinists and socialists of the intelligentsia.

In Siberia Dostoyevsky experienced what he called the "regeneration" of his convictions. He rejected the condescending attitude of intellectuals, who wanted to impose their political ideas on society, and came to believe in the dignity and fundamental goodness of common people. He describes this change in his sketch "The Peasant Marey" (which appears in *The Diary of a Writer*). Dostoyevsky also became deeply attached to Russian Orthodoxy, as the religion of the common people, although his faith was always at war with his skepticism. In one famous letter he describes how he thirsts for faith "like parched grass" and concludes: "if someone proved to me that Christ is outside the truth, and that *in reality* the truth were outside of Christ, then I should prefer to remain with Christ rather than with the truth."

Epilepsy

Dostoyevsky suffered his first attacks of epilepsy while in prison. No less than his accounts of being led to execution, his descriptions of epileptic seizures (especially in *The Idiot*) reveal the heights and depths of the human soul. As Dostoyevsky and his hero Myshkin experience it, the moment just before an attack grants the sufferer a strong sensation of perfect harmony and of overcoming time. In 1857 Dostoyevsky married a consumptive widow, Mariya Dmitriyevna Isayeva (she died seven years later); the unhappy marriage began with her witnessing one of his seizures on their honeymoon.

Works of the 1860s. Upon his return to Russia, Dostoyevsky plunged into literary activity. With his brother Mikhail, he edited two influential journals, first *Vremya* ("Time"; 1861–63), which was closed by the government on account of an objectionable article, and then *Epokha* ("Epoch"; 1864–65), which collapsed after the death of Mikhail. After first trying to maintain a middle-of-the-road position, Dostoyevsky began to attack the radicals, who virtually defined the Russian intelligentsia. Dostoyevsky was repulsed by their materialism, their utilitarian morality, their reduction of art to propaganda, and, above all, their denial of individual freedom and responsibility. For the remainder of his life, he maintained a deep sense of the danger of radical ideas, and so his post-Siberian works came to be held in suspicion by the Soviet regime.

Notes from the Underground. In the first part of *Zapiski iz podpolya* (1864; *Notes from the Underground*) an unnamed first-person narrator delivers a brilliant attack on a set of beliefs shared by liberals and radicals: that it is possible to discover the laws of individual psychology, that human beings consequently have no free choice, that history is governed by laws, and that it is possible to design a utopian society based on the laws of society and human nature. Even if such a society could be built, the underground man argues, people would hate it just because it denied them caprice and defined them as utterly predictable. In the novella's second part the underground man recalls incidents from his past, which show him behaving, in answer to determinism, according to sheer spite. Dostoyevsky thus makes clear that the underground man's irrationalist solution is no better than the rationalists' systems. *Notes from the Underground* also parodied the bible of the radicals, Nikolay Chernyshevsky's utopian fiction *What Is to Be Done?* (1863).

Stay in western Europe. For several reasons, Dostoyevsky spent much of the 1860s in western Europe: he wanted to see the society that he both admired for its culture and deplored for its materialism, he was hoping to resume an affair with the minor author Appolinariya Suslova, he was escaping his creditors in Russia, and he was disastrously attracted to gambling. An unscrupulous publisher offered him a desperately needed advance on the condition that he deliver a novel by a certain date; the publisher was counting on the forfeit provisions, which would allow him nine years to publish all of Dostoyevsky's works for free. With less than a month remaining, Dostoyevsky hired a stenographer and dictated his novel *Igrok* (1866; *The Gambler*)—based on his relations with Suslova and the psychology of compulsive gambling—which he finished just on time. A few months later (1867) he married the stenographer, Anna Grigoryevna Snitkina. She at last put his life and finances in order and created stable conditions for his work and new family. They had four children, of whom two survived to adulthood.

The Gambler

Crime and Punishment. Written at the same time as *The Gambler, Prestupleniye i nakazaniye* (1866; *Crime and Punishment*) describes a young intellectual, Raskolnikov, willing to gamble on ideas. He decides to solve all his problems at a stroke by murdering an old pawnbroker woman. Contradictory motives and theories all draw him to the crime. Utilitarian morality suggests that killing her is a positive good because her money could be used to help many others. On the other hand, Raskolnikov reasons that belief in good and evil is itself sheer prejudice, a mere relic of religion, and that, morally speaking, there is no such thing as crime. Nevertheless, Raskolnikov, despite his denial of morality, sympathizes with the unfortunate and so wants to kill the pawnbroker just because she is an oppressor of the weak. His most famous theory justifying murder divides the world into extraordinary people, such as Solon, Caesar, and Napoleon, and ordinary people, who simply serve to propagate the species. Extraordinary people, he theorizes, must have "the right to transgress," or progress would be impossible. Nothing could be further from Dostoyevsky's own morality, based on the infinite worth of each human soul, than this Napoleonic theory, which Dostoyevsky viewed as the real content of the intelligentsia's belief in its superior wisdom.

Raskolnikov's Napoleonic theory

After committing the crime, Raskolnikov unaccountably finds himself gripped by "mystic terror" and a horrible sense of isolation. The detective Porfiry Petrovich, who guesses Raskolnikov's guilt but cannot prove it, plays psychological games with him until the murderer at last confesses. Meanwhile, Raskolnikov tries to discover the real motive for his crime but never arrives at a single answer. In a famous commentary, Tolstoy argued that there was no single motive but rather a series of "tiny, tiny alterations" of mood and mental habits. Dostoyevsky's brilliance in part lies in his complex rethinking of such concepts as motive and intention.

Crime and Punishment also offers remarkable psychological portraits of a drunkard, Marmeladov, and of a vicious amoralist haunted by hallucinations, Svidrigailov. Raskolnikov's friend Razumikhin voices the author's distaste for an ideological approach to life; Razumikhin's own life exemplifies how one can solve problems neither by grand ideas nor by dramatic gambles but by slow, steady, hard work.

Quite deliberately, Dostoyevsky made the heroine of the story, Sonya Marmeladova, an unrealistic symbol of pure Christian goodness. Having become a prostitute to support her family, she later persuades Raskolnikov to confess and then follows him to Siberia. In the novel's epilogue, the prisoner Raskolnikov, who has confessed not out of remorse but out of emotional stress, at first continues to maintain his amoral theories but at last is brought to true repentance by a revelatory dream and by Sonya's good-

ness. Critical opinion is divided over whether the epilogue is artistically successful.

The Idiot. Dostoyevsky's next major novel, *Idiot* (1868–69; *The Idiot*), represents his attempt to describe a perfectly good man in a way that is still psychologically convincing—seemingly an impossible artistic task. If he could succeed, Dostoyevsky believed, he would show that Christ-like goodness is indeed possible; and so the very writing of the work became an attempt at what might be called a novelistic proof of Christianity.

The work's hero, Prince Myshkin, is indeed perfectly generous and so innocent as to be regarded as an idiot; however, he is also gifted with profound psychological insight. Unfortunately, his very goodness seems to bring disaster to all he meets, even to the novel's heroine, Nastasya Filippovna, whom he wishes to save. With a remarkably complex psychology, she both accepts and bitterly defies the world's judgment of her as a fallen woman. Ippolit, a spiteful young man dying of consumption, offers brilliant meditations on art, on death, on the meaninglessness of dumb brutish nature, and on happiness, which, to him, is a matter of the very process of living.

Dostoyevsky's last decade. *The Possessed.* Dostoyevsky's next novel, *Besy* (1872; *The Possessed*), earned him the permanent hatred of the radicals. Often regarded as the most brilliant political novel ever written, it interweaves two plots. One concerns Nikolay Stavrogin, a man with a void at the centre of his being. In his younger years Stavrogin, in a futile quest for meaning, had embraced and cast off a string of ideologies, each of which has been adopted by different intellectuals mesmerized by Stavrogin's personality. Shatov has become a Slavophile who, like Dostoyevsky himself, believes in the "God-bearing" Russian people. Existentialist critics (especially Albert Camus) became fascinated with Kirillov, who adopts a series of contradictory philosophical justifications for suicide. Most famously, Kirillov argues that only an utterly gratuitous act of self-destruction can prove that a person is free because such an act cannot be explained by any kind of self-interest and therefore violates all psychological laws. By killing himself without reason, Kirillov hopes to become the "man-god" and so provide an example for human freedom in a world that has denied Christ (the God-man).

It is the novel's other plot that has earned Dostoyevsky the reputation of a political prophet. It describes a cell of revolutionary conspirators led by Pyotr Stepanovich Verkhovensky, who binds the group together by involving them in murdering Shatov. (This incident was based on the scheme of a real revolutionary of the time, Sergey Nechayev.) In lines that anticipate Soviet and Maoist cultural policy, Pyotr Stepanovich predicts that, when the revolution comes, "Cicero will have his tongue cut out, Copernicus will have his eyes put out, Shakespeare will be stoned," all in the name of "equality."

Pyotr is the son and Stavrogin the former student of the novel's weak but endearing liberal, Stepan Trofimovich Verkhovensky. Dostoyevsky suggests that the madness of the radical sons derives from their fathers' liberal skepticism, mockery of traditional morals, and, above all, neglect of the family.

A Writer's Diary and other works. In 1873 Dostoyevsky assumed the editorship of the conservative journal *Grazhdanin* ("The Citizen"), where he published an irregular column entitled "Dnevnik pisatelya" ("The Diary of a Writer"). He left *Grazhdanin* to write *Podrostok* (1875; *A Raw Youth*, also known as *The Adolescent*), a relatively unsuccessful and diffuse novel describing a young man's relations with his natural father.

A Raw Youth

In 1876–77 Dostoyevsky devoted his energies to *Dnevnik pisatelya*, which he was now able to bring out in the form he had originally intended. A one-man journal, for which Dostoyevsky served as editor, publisher, and sole contributor, the *Diary* represented an attempt to initiate a new literary genre. Issue by monthly issue, the *Diary* created complex thematic resonances among diverse kinds of material: short stories, plans for possible stories, autobiographical essays, sketches that seem to lie on the boundary between fiction and journalism, psychological analyses of sensational crimes, literary criticism, and political commentary. The *Diary* proved immensely popular and financially rewarding, but as an aesthetic experiment it was less successful, probably because Dostoyevsky, after a few intricate issues, seemed unable to maintain his complex design. Instead, he was drawn into expressing his political views, which, during these two years, became increasingly extreme. Specifically, Dostoyevsky came to believe that western Europe was about to collapse, after which Russia and the Russian Orthodox church would create the kingdom of God on earth and so fulfill the promise of the Book of Revelation. In a series of anti-Catholic articles, he equated the Roman Catholic church with the socialists because both are concerned with earthly rule and maintain (Dostoyevsky believed) an essentially materialist view of human nature. He reached his moral nadir with a number of anti-Semitic articles.

The *Diary's* most famous sections are usually known from anthologies and so are separated from the context in which they were designed to fit. These sections include four of his best short stories—"Krotkaya" ("The Meek One"), "Son smeshnogo cheloveka" ("The Dream of a Ridiculous Man"), "Malchik u Khrista na elke" ("The Heavenly Christmas Tree"), and "Bobok"—as well as a number of autobiographical and semifictional sketches, including "Muzhik Marey" ("The Peasant Marey"), "Stoletnaya" ("A Hundred-Year-Old Woman"), and a satire, "Spiritizm. Nechto o chertyakh Chrezychaynaya khitrost chertey, esli tolko eto cherti" ("Spiritualism. Something about Devils. The Extraordinary Cleverness of Devils, If Only These Are Devils").

The Brothers Karamazov. Dostoyevsky's last and probably greatest novel, *Bratya Karamazovy* (1879–80; *The Brothers Karamazov*), focuses on his favourite theological and philosophical themes: the origin of evil, the nature of freedom, and the craving for faith. A profligate and vicious father, Fyodor Pavlovich Karamazov, mocks everything noble and engages in unseemly buffoonery at every opportunity. When his sons were infants, he neglected them not out of malice but simply because he "forgot" them. The eldest, Dmitry, a passionate man capable of sincerely loving both "Sodom" and "the Madonna" at the same time, wrangles with his father over money and competes with him for the favours of a "demonic" woman, Grushenka. When the old man is murdered, circumstantial evidence leads to Dmitry's arrest for the crime, which actually has been committed by the fourth, and illegitimate, son, the malicious epileptic Smerdyakov.

The youngest legitimate son, Alyosha, is another of Dostoyevsky's attempts to create a realistic Christ figure. Following the wise monk Zosima, Alyosha tries to put Christian love into practice. The narrator proclaims him the work's real hero, but readers are usually most interested in the middle brother, the intellectual Ivan.

Alyosha

Like Raskolnikov, Ivan argues that, if there is no God and no immortality, then "all is permitted." And, even if all is not permitted, he tells Alyosha, one is responsible only for one's actions but not for one's wishes. Of course, the Sermon on the Mount says we are responsible for our wishes, and, when old Karamazov is murdered, Ivan, in spite of all his theories, comes to feel guilty for having desired his father's death. In tracing the dynamics of Ivan's guilt, Dostoyevsky in effect provides a psychological justification for Christian teaching. Evil happens not just because of a few criminals but because of a moral climate in which all people participate by harbouring evil wishes. Therefore, as Father Zosima teaches, "everyone is responsible for everyone and for everything."

The novel is most famous for three chapters that may be ranked among the greatest pages of Western literature. In "Rebellion," Ivan indicts God the Father for creating a world in which children suffer. Ivan has also written a "poem," "The Grand Inquisitor," which represents his response to God the Son. It tells the story of Christ's brief return to earth during the Spanish Inquisition. Recognizing him, the Inquisitor arrests him as "the worst of heretics" because, the Inquisitor explains, the church has rejected Christ. For Christ came to make people free, but, the Inquisitor insists, people do not want to be free, no matter what they say. They want security and certainty

"The Grand Inquisitor"

rather than free choice, which leads them to error and guilt. And so, to ensure happiness, the church has created a society based on "miracle, mystery, and authority." The Inquisitor is evidently meant to stand not only for medieval Roman Catholicism but also for contemporary socialism. "Rebellion" and "The Grand Inquisitor" contain what many have considered the strongest arguments ever formulated against God, which Dostoyevsky includes so that, in refuting them, he can truly defend Christianity. It is one of the greatest paradoxes of Dostoyevsky's work that his deeply Christian novel more than gives the Devil his due.

In the work's other most famous chapter, Ivan, now going mad, is visited by the Devil, who talks philosophy with him. Quite strikingly, this Devil is neither grand nor satanic but petty and vulgar, as if to symbolize the ordinariness and banality of evil. He also keeps up with all the latest beliefs of the intelligentsia on earth, which leads, in remarkably humorous passages, to the Devil's defense of materialism and agnosticism. The image of the "petty demon" has had immense influence on 20th-century thought and literature.

In 1880 Dostoyevsky delivered an electrifying speech about the poet Pushkin, which he published in a separate issue of *The Diary of a Writer* (August 1880). After finishing *Karamazov,* he resumed the monthly *Diary* but lived to publish only a single issue (January 1881) before dying of a hemorrhage on Jan. 28 (Feb. 9, New Style), 1881, in St. Petersburg.

MAJOR WORKS

NOVELS AND NOVELLAS: *Bednyye lyudi* (1846; *Poor Folk,* 1894); *Dvoynik* (1846; *The Double,* 1917); *Netochka Nezvanova* (1849; *Nyetochka Nyezvanov,* 1920); *Dyadyushkin Son* (1859; *Uncle's Dream,* 1888); *Selo Stepanchikovo i yego obitateli* (1859; *The Friend of the Family,* 1887); *Zapiski iz myortvogo doma* (1861–62; *Buried Alive; or, Ten Years of Penal Servitude in Siberia,* 1881, better known as *The House of the Dead*); *Unizhennyye i oskorblyonnyye* (1861; *Injury and Insult,* 1886, better known as *The Insulted and Injured*); *Zimniye zametki o letnikh vpechatleniyakh* (1863; *Winter Notes on Summer Impressions,* 1955); *Zapiski iz podpolya* (1864; *Letters from the Underworld,* 1913, better known as *Notes from the Underground*); *Prestupleniye i nakazaniye* (1866; *Crime and Punishment,* 1886); *Igrok* (1866; *The Gambler,* 1887); *Idiot* (1868–69; *The Idiot,* 1887); *Vechny muzh* (1870; *The Permanent Husband,* 1888, better known as *The Eternal Husband*); *Besy* (1872; *The Possessed,* 1913); *Dnevnik pisatelya* (1873–74, 1876–77, 1880, 1881; *The Diary of a Writer,* 1949); *Podrostok* (1875; *A Raw Youth,* 1916); *Bratya Karamazovy* (1879–80; *The Brothers Karamazov,* 1912).

SHORT STORIES: "Krotkaya" (1876; "The Gentle Maiden," 1913, also known as "The Meek One"); "Son smeshnogo cheloveka" (1877; "The Dream of a Queer Fellow," 1916, better known as "The Dream of a Ridiculous Man").

EDITIONS IN RUSSIAN AND IN ENGLISH TRANSLATION: The authoritative edition of Dostoyevsky's complete works is *Polnoe sobranie sochineniĭ F.M. Dostoevskogo,* 30 vol. (1972–90). As a rule, the best translations for capturing the artistic power of the fiction are still the ones in *The Novels of Fyodor Dostoevsky,* trans. by CONSTANCE GARNETT, 12 vol. (1912–20), available in many later editions, including in the *Modern Library* series. Since Garnett translated *The Possessed,* the missing chapter "At Tihon's," which his publisher had not allowed Dostoyevsky to publish, has come to light; the 1936 edition includes it in a rendition by Avrahm Yarmolinsky. Garnett's translation of *Notes from the Underground* was revised by RALPH E. MATLAW, *Notes from Underground, and The Grand Inquisitor* (1960), which also contains extracts from Chernyshevsky's work *What Is to Be Done?.*

Garnett has often been faulted for smoothing out the low and colloquial passages in Dostoyevsky. They are, however, admirably captured in *The Brothers Karamazov* (1990) and *Crime and Punishment* (1992), both trans. by RICHARD PEVEAR and LARISSA VOLOKHONSKY; unfortunately, these versions are not as successful as Garnett's in capturing other passages, especially lyrical prose. Another good rendition is *Notes from Underground,* trans. and ed. by MICHAEL R. KATZ (1989). *The Gambler, with Polina Suslova's Diary,* trans. by VICTOR TERRAS and ed. by EDWARD WASIOLEK (1972), is also of interest. *Netochka Nezvanova,* trans. by ANN DUNNIGAN (1970), is a fine version of this unfinished work.

For a long time, *The Diary of a Writer,* trans. by BORIS BRASOL, 2 vol. (1949, reprinted 1985), was the only, and extremely poor, translation. The superior version, *A Writer's Diary,* trans. by KENNETH LANTZ, 2 vol. (1993–94), is accompanied by helpful annotations explaining topical references. A selection of Dostoyevsky's journalism is *Dostoevsky's Occasional Writings,* trans. by DAVID MAGARSHACK (1963). His quasi-journalistic account of his first trip abroad is *Winter Notes on Summer Impressions,* trans. by DAVID PATTERSON (1988). Dostoyevsky's letters are available in *Complete Letters,* ed. and trans. by DAVID LOWE and RONALD MEYER, 5 vol. (1988–91).

The notebooks for Dostoyevsky's five long novels are available in editions that not only translate but also helpfully organize the Russian material; they are all edited by EDWARD WASIOLEK: *The Notebooks for Crime and Punishment* (1967), *The Notebooks for The Idiot* (1967), *The Notebooks for The Possessed* (1968), *The Notebooks for A Raw Youth* (1969), and *The Notebooks for The Brothers Karamazov* (1971). Additional notebooks are translated in *The Unpublished Dostoevsky: Diaries and Notebooks (1860–1881),* ed. by CARL R. PROFFER, 3 vol. (1973–76).

BIBLIOGRAPHY

Biography. The superior biography of Dostoyevsky (in any language) is the still incomplete multivolume study by JOSEPH FRANK, *Dostoevsky: The Seeds of Revolt, 1821–1849* (1976), *Dostoevsky: The Years of Ordeal, 1850–1859* (1983), *Dostoevsky: The Stir of Liberation, 1860–1865* (1986), and *Dostoevsky: The Miraculous Years, 1865–1871* (1995); these volumes also offer excellent portraits of the Russian intellectual milieu and illuminating readings of Dostoyevsky's works. Another good biography is LEONID GROSSMAN, *Dostoevsky* (1974; originally published in Russian, 2nd ed., 1965). One may also consult the diary of Dostoyevsky's mistress, Suslova, mentioned above; and the reminiscences of his second wife, ANNA DOSTOEVSKY, *Dostoevsky: Reminiscences* (1975; originally published in Russian, 2nd ed., 1971).

Criticism. Several studies survey Dostoyevsky's career with a chapter on each major work. The one to read first is KONSTANTIN MOCHULSKY, *Dostoevsky: His Life and Work* (1967; originally published in Russian, 1947). Others of note are EDWARD WASIOLEK, *Dostoevsky: The Major Fiction* (1964); MICHAEL HOLQUIST, *Dostoevsky and the Novel* (1977, reissued 1986); and RICHARD PEACE, *Dostoevsky: An Examination of the Major Novels* (1971, reissued 1992).

The most brilliant and most controversial book on Dostoyevsky is MIKHAIL BAKHTIN, *Problems of Dostoevsky's Poetics,* ed. and trans. by CARYL EMERSON (1984; originally published in Russian, 2nd ed., rev. and enlarged, 1963). Other classics of Russian criticism in English include a study by a prominent existentialist theologian, NICHOLAS BERDYAEV, *Dostoievsky,* trans. by DONALD ATTWATER (1934, reissued 1974; originally published in Russian, 1923). Also available is an essay originally published in Russian in 1903 by the Russian existentialist and Nietzschean LEV SHESTOV, "Dostoevsky and Nietzsche: The Philosophy of Tragedy," in his *Dostoevsky, Tolstoy, and Nietzsche* (1969), pp. 141–332.

DONALD FANGER, *Dostoevsky and Romantic Realism: A Study of Dostoevsky in Relation to Balzac, Dickens, and Gogol* (1965, reissued 1974), places Dostoyevsky in the context of European literature. On Dostoyevsky's obsessions and creative process, an outstanding, if diffuse, work is JACQUES CATTEAU, *Dostoyevsky and the Process of Literary Creation* (1989). The best study of Dostoyevsky's aesthetics is ROBERT LOUIS JACKSON, *Dostoevsky's Quest for Form: A Study of His Philosophy of Art,* 2nd ed. (1978), while his *The Art of Dostoevsky: Deliriums and Nocturnes* (1981), is especially good on *The House of the Dead.* ROBERT LOUIS JACKSON (ed.), *Dostoevsky: New Perspectives* (1984), is a fine critical anthology. Dostoyevsky's anti-Semitism is treated in DAVID I. GOLDSTEIN, *Dostoyevsky and the Jews,* trans. from French (1981); and in GARY SAUL MORSON, "Dostoevsky's Anti-Semitism and the Critics," *Slavic and East European Journal,* 27(8):302–317 (Fall 1983).

The outstanding study of *The Idiot* is ROBIN FEUER MILLER, *Dostoevsky and The Idiot: Author, Narrator, and Reader* (1981). On *Crime and Punishment,* ROBERT LOUIS JACKSON (ed.), *Twentieth Century Interpretations of Crime and Punishment* (1974), is a superb anthology of pithy extracts. Two divergent interpretations of *A Writer's Diary* by the same author are GARY SAUL MORSON, *The Boundaries of Genre: Dostoevsky's Diary of a Writer and the Traditions of Literary Utopia* (1981), and "Dostoevsky's Great Experiment," an introductory study to the Lantz translation of the *Diary* mentioned above. There are three outstanding books on *The Brothers Karamazov:* the reader should begin with ROBIN FEUER MILLER, *The Brothers Karamazov: Worlds of the Novel* (1992); and then turn to ROBERT L. BELKNAP, *The Structure of The Brothers Karamazov* (1967, reprinted 1989), and *The Genesis of The Brothers Karamazov: The Aesthetics, Ideology, and Psychology of Text Making* (1990).

(G.S.M.)

Drafting

Drafting provides graphic communication for the design and fabrication of machines, structures, systems, or various products. At the design stage, both freehand and mechanical drawings serve the functions of inspiring and guiding the designer and of communicating among the designer, collaborators, production department, and marketing or management personnel. Sometimes drafting is taken to mean only exact mechanical drawing procedures; at the design stage exact mechanical drawings can clarify, confirm, or disqualify a scheme that looked promising in a freehand sketch. Actually, both the sketch and the exact mechanical drawing are essential parts of the process of designing, and both belong to the field of drafting. After the basic design has been established, drafting skills aid in the development and transmission of the wealth of data necessary for the production and assembly of the parts. For an automobile, a skyscraper, or a spacecraft, tens of thousands of drawings may be needed to convey all of the requirements of the finished product from the designers to the fabricators.

The completion of the set of drawings necessary for the manufacture of a product or the construction of a project involves three important factors: (1) itemization of every detail and requirement of the final product or project; (2) application of good judgment and knowledge of standard drafting procedures to select the combination of drawings and specifications that will convey the information identified in stage (1) in the clearest possible manner; and (3) deployment of skilled personnel and suitable equipment to produce the documents specified in stage (2).

Drafting is based on the concept of orthographic projection, which in turn is the principal concern of the branch of mathematics called descriptive geometry. Although preceded by the publication of related material and followed by an extensive development, the book *Géométrie descriptive* (1798) by Gaspard Monge, an 18th-century French mathematician, is regarded as the first exposition of descriptive geometry and the formalization of orthographic projection. The growth and development of the drafting profession were favoured by the application of the concepts published by Monge, the need to manufacture interchangeable parts, the introduction of the blueprinting process, and the economy offered by a set of drawings that in most cases made the building of a working model unnecessary.

Persons with a variety of skills and specialties are essential to the design and implementation of engineering and architectural projects. Drafting provides communication among them and coordination of their activities. The designer has primary responsibility for the basic conception and final solution but depends upon the support of several levels of drafters who prepare graphic studies of details; determine fits, clearances, and manufacturing feasibility; and prepare the working drawings. The delineator, or technical illustrator, converts preliminary or final drawings into pictorial representations, usually perspective constructions in full colour to help others visualize the product, to inform the public, to attract investment, or to promote sales. Before undertaking their own drawings, persons entering the profession of drafting may trace drawings to revise or repair them, then advance to the preparation of detail drawings, tables of materials, schedules of subassemblies (such as doors and windows), and the dimensioning of drawings initiated by more experienced colleagues. The wide spectrum of activities demanded of a design team requires that its members combine experience and creativity with skills in visualization, analysis, and delineation and with knowledge of materials, fabrication processes, and standards.

It is the responsibility of the manufacturing, fabricating, or construction workers to follow a set of drawings and specifications exactly; there should be no need for them to ask questions or make decisions regarding particulars of the design. All such particulars are the responsibility of the design team; the drawings must clearly convey all necessary information so that the functional requirements of and regulatory restrictions on the completed product or project are satisfied, the mechanical properties of the materials are appropriate, and the machining operations and assembly or erection procedures are possible.

The strictly utilitarian objectives of drafting and its emphasis on clarity and accuracy clearly differentiate it from the allied art form covered in the article DRAWING. Cartographic drafting is treated in the article MAPPING AND SURVEYING. Some specific applications of drafting are dealt with in the articles BUILDING CONSTRUCTION: *Modern building practices;* DECORATIVE ARTS AND FURNISHINGS: *Interior design;* and INDUSTRIES, MANUFACTURING: *Clothing and footwear industry.*

This article is divided into the following sections:

TYPES OF DRAWINGS

Varying according to the product or project, the set of drawings generally contains detail drawings (also called working drawings), assembly drawings, section drawings, plans (top views), and elevations (front views). For manufacturing a machine, the shape and size of each individual part, except standard fasteners, are described in a detail drawing, and at least one assembly drawing indicates how the parts fit together. To clarify interior details or the fitting together of parts, it may be necessary to prepare a section drawing, showing a part or assembly as though it had been cut by a plane, with a portion of the object removed. For constructing a building, plans, elevations, section drawings, and detail drawings are necessary to convey the information needed to estimate costs and then erect the structure. In this case the detail drawings contain exact information about such features as elevators, stairways, cabinetwork, and the framing of windows, doors, and spandrels. Different information appears in the set of drawings for a bridge, a dam, or a highway, but in each case the differences are related to the best manner of conveying the needed information.

DIMENSIONS AND TOLERANCES

The sizes of parts and overall sizes of assemblies are conveyed by dimensions placed on the drawing. The basic objective in dimensioning a drawing is to give the manufacturing or construction personnel the dimensions they need to do their work without requiring them to add, subtract, or estimate distances. If mass production is to be undertaken, special attention must be given to the dimensions of interchangeable parts that fit together. To dimension a distance as, say, two inches cannot require

that it be exactly two (2.000 . . .) inches, because no one can machine material with such precision. Particularly for parts of machinery, the designer must specify the acceptable range for the size of a hole, a shaft, or other feature requiring proper fit—perhaps 1.995 to 2.005 inches. The difference between the acceptable maximum and minimum dimensions given for a hole, shaft, or other feature is known as the tolerance. In the example above the tolerance is 0.010 (that is, 2.005 − 1.995) inch. Unsatisfactory tolerancy of mating parts ordinarily results in a machine with improper function or greatly reduced useful life. On the other hand, the cost of production increases greatly as tolerances are made stricter. It is an important design decision to require the correct level of tolerance for the functioning of any particular product. Additional information on a set of drawings indicates the materials to be used and the types of finish required on the surfaces.

SYSTEMS OF REPRESENTATION

Perspective. The shapes of all the parts and their interrelation are exactly described by the representation of that information in the set of drawings. Such description can be a lesser or greater challenge, depending on the complexity of the design. In the 15th century some of the leading artists and architects developed geometric schemes of perspective. Geometric perspective is a drawing method by which it is possible to depict a three-dimensional form as a two-dimensional image that closely resembles the scene as visualized by the human eye. The camera produces photographs with such resemblance. Images produced by the eye, the camera, and systems of perspective can all be interpreted in terms of what is known as central projection. Lines of sight may be thought of as extending from the points of the object under observation to a central point of convergence—the lens of the eye or the camera, or the reference point of the perspective construction. In the case of the eye these lines of sight are focused by the lens into an image on the curved retina. In the camera they pass through the lens to form an image on a flat piece of film. In systems of geometric perspective the converging lines of sight form an image on an imaginary picture plane located between the object and the central point of the construction.

The eye, the camera, and geometric perspective

Perspective drawings and photographs are easily interpreted because they closely resemble visual images. This resemblance includes the diminution of the relative size of the representations of portions of the object that recede from the viewer and the distortion of the angular relations of the lines of the object. The object shown in perspective in Figure 1A may be interpreted as a cube. The same object is represented in Figure 1B according to the projectional system ordinarily used for engineering and architectural drawings; there it is evident that the object is not a cube. Such projections are used because they convey accurate information about the shape of the object.

Orthographic projection. The projection used for engineering and architectural drawings is called orthogonal ("right-angled") or orthographic because the lines of sight from points on the object to the picture plane of the image are perpendicular to that plane. Thus, the lines of sight, called projectors, are parallel rather than convergent (as they are in the central projection of the eye, the camera, and geometric perspective).

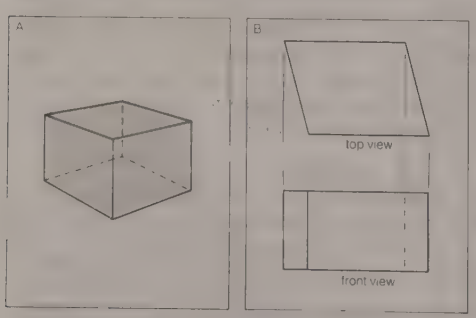

Figure 1: *Two techniques of representing an object.* (A) Perspective drawing, suggesting that the object is cubical. (B) Orthographic top and front views, revealing that the object is not cubical.

Descriptive geometry. Monge's reference system consisted of a vertical plane (V in Figure 2A) and a horizontal plane (H) that intersected in a ground line. As in Figure 2A, Monge numbered the four quadrants formed by V and H I, II, III, and IV. Figure 2A also shows two arrows, D_1 perpendicular to H and D_2 perpendicular to V. Each arrow represents the direction of projection from points on any object under study to one of the reference planes. Such an object is the L-shaped block located in the first quadrant. Monge introduced the concepts of the reference system, the formation of views by projectors perpendicular to the reference planes, the revolving of the H plane into coincidence with the V plane about the ground line as indicated by the curved arrows, and the retention of the images on the planes after the object had been removed and the H plane revolved. Figure 2B illustrates the final result: the projection on V is regarded as the front view, and the projection on H as the top view.

Monge's system

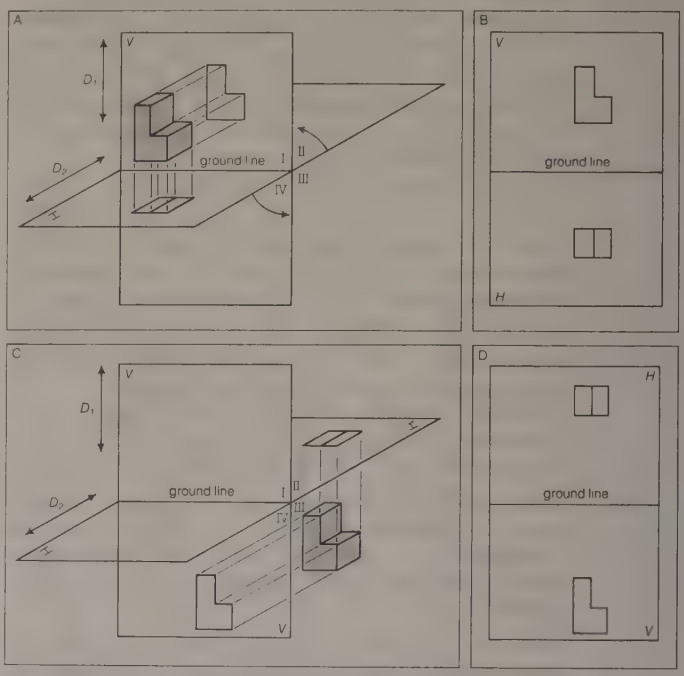

Figure 2: *Orthographic projections of a three-dimensional object onto vertical and horizontal planes.* (A) Object located in the first of four quadrants defined by intersecting planes. (B) Result of rotating the horizontal plane into coincidence with the vertical plane. (C) The same object located in the third quadrant. (D) Result of rotating the horizontal plane as in (B), showing exchanged positions of top and front views.

If the object were placed in the third quadrant (see Figures 2C and 2D), the projections would be exactly the same, but their relative locations on the paper would be reversed. If the object were located in the second quadrant, the two projections would have the same shape and size as in Figures 2B and 2D. Depending on the location of the object in the second quadrant, however, now either projection might be located above the other or one projection might overlap the other. The same is the case if the object were located in the fourth quadrant. This uncertainty is the reason that commercial use is limited to first- or third-quadrant projection. First-quadrant projection is often referred to as first-angle projection, and third-quadrant projection as third-angle projection.

Regardless of the quadrant (or angle) used, the views or projections are formed by the intersection of the projectors and the reference planes. Established conventions determine which points of the object are projected. If projectors were extended from every point on the object to the reference planes, the views would be silhouettes and would fail in their purpose of defining the object. The accepted rule is to project (1) all points on the edges between plane sur-

Choice of points to be projected

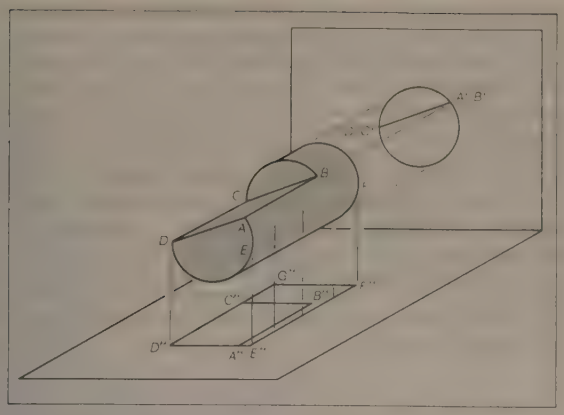

Figure 3: Selection of points to be projected in preparing orthographic views (see text).

faces that bound the object and (2) all points at which the projectors forming the view are tangent to curved surfaces of the object. Figure 3 illustrates these two sets of points. *AB* is the line of intersection of the cylindrical surface and plane surface *ABCD*. *CB* is the line of intersection of two plane surfaces. *EF* is not the line of intersection of two surfaces of the object, but projectors forming the top view are tangent to the cylindrical surface along the straight path from *E* to *F*, and thus E^HF^H properly appears in the top view. (The superscript *H* is used here to denote the projection on the *H* plane, and, similarly, *V* is used to denote the projection on the *V* plane.) *CD* is the line of intersection of the cylindrical surface and plane *ABCD*, but C^HG^H results from the tangency of projectors along the cylindrical surface. Every line projected in the identical front view of this object is a line of intersection of surfaces. *AD*, *BC*, and the plane *ABCD* all project as the same straight line in the front view because the plane *ABCD* is parallel to the projectors for that view.

Ambiguity. Ambiguity must be avoided in the views, dimensions, and notes of a set of drawings. Figure 4A shows pictorial representations of three different objects for which the identical front and top views in Figure 4B are correct. The ambiguity in the shape description provided by front and top views alone can be eliminated by adding a third, or side, view obtained by projecting the object onto a vertical plane perpendicular to *V*. In Figure 4B each set of three views describes only one of the objects without ambiguity.

In commercial or industrial practice, sets of drawings ordinarily provide at least three views of any part that is not a stamping, a gasket, a flat wrench, or other essentially two-dimensional form. Depending on the shape of the part, there may be a left-side view, a right-side view, or both. There may be reason for a back view, a bottom view, or both. Additional views are discussed below.

Hidden lines. It is standard practice to use dashes to represent any line of an object that is hidden from view.

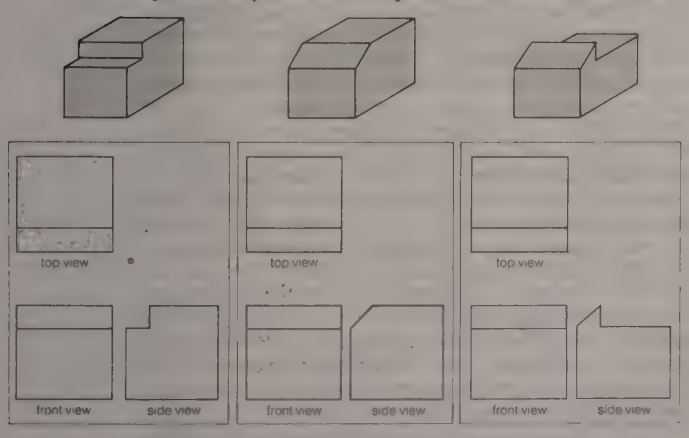

Figure 4: *Three objects with identical top and front views.* (Top row) Pictorial drawings. (Bottom row) Top, front, and side views, showing how the side views resolve the ambiguity.

A drafter—in deciding whether a line in a view should be represented as hidden or as visible—relies on the fact that in third-angle projection the near side of the object is near the adjacent view, but in first-angle projection the near side of the object is remote from the adjacent view. In Figure 4B (third-angle projection) the top of the front view is near the top view; the front of the top view is near the front view; and the front of the side view is near the front view. In first-angle projection, however, the top of the front view is remote from the top view; the front of the top view is remote from the front view, and the front of the side view is remote from the front view. In a third-angle projection, what is remote in an adjacent view cannot hide what is near in that view.

Advantages of third-angle projection

Figure 5 shows a pictorial representation of an object and the third-angle projections of that object. The arrangement of the three views gives intuitive reinforcement to the correct selection of the line shown as hidden in each view because it is blocked by portions of the object that are nearer in the adjacent views. The number of hidden lines in a view of a complicated object may be very great. For purposes of studying visibility, the direction of projection may be thought of as always vertically downward for a top view, always horizontally from front to back for a front view, and always horizontally right-to-left for a right-side view.

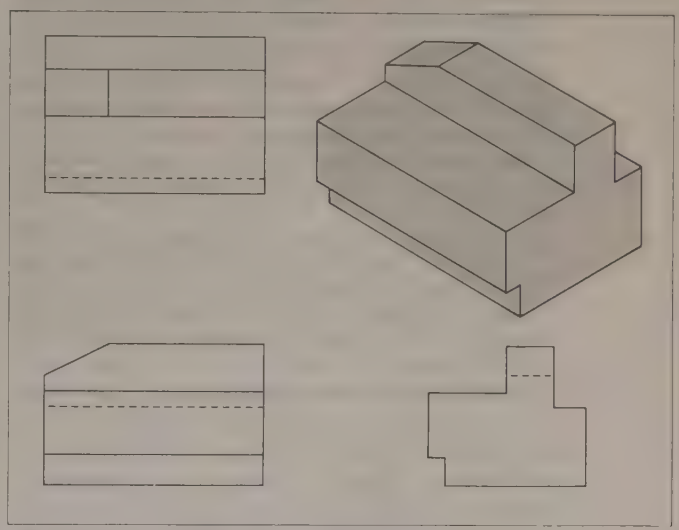

Figure 5: Use of dashed lines to represent edges hidden in views of a complicated object.

In Figure 5 the hidden lines in the views could be identified by visualizing the object, a process that can be quite difficult for complicated objects. The following basic principle of descriptive geometry is useful in analyzing such a problem:

I. If any point is projected orthogonally onto each of two perpendicular planes and the planes are rotated into coincidence about their line of intersection, then the projections of the point on the two planes will lie on a straight line perpendicular to the line of intersection.

Figure 6 demonstrates this statement. Although the ground line, or line of intersection of *H* and *V*, is seldom drawn in the representations of front and top or of front, top, and side views of objects, it is understood to be horizontal. Thus for any point *P*, P^H and P^V lie on a vertical line of the drawing.

A tetrahedron (triangular pyramid) with vertices *A*, *B*, *C*, and *D* is shown in third-angle projection in Figure 7. The edges *AC* and *BD* do not intersect, although their projections do. To determine which of these two edges is visible in the top view, the drafter considers location *M*, where the *H* projection of a point on *AC* and the *H* projection of a point on *BD* coincide. By principle I the *V* projections of these two points will lie on a vertical line from the crossing of A^HC^H and B^HD^H. A vertical construction line in Figure 7 indicates that the point on *BD*

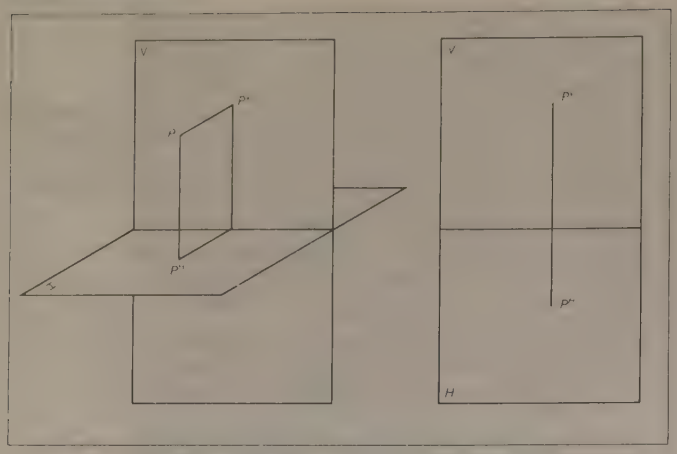

Figure 6: *Descriptive geometry, principle I (see text).* If a point is projected orthogonally onto two intersecting planes, which then are rotated into coincidence, the projections lie on a line perpendicular to the former line of intersection.

is nearer to the top of the tetrahedron than the point on *AC*. This means that *BD* crosses above *AC*, so that *BD* must be visible in the top view and *AC* hidden. Similarly, to study the visibility of these lines in the front view, the vertical construction line is drawn through *Q*, the crossing of $A^V C^V$ and $B^V D^V$; this procedure indicates that the point on *BD* is nearer to the front of the tetrahedron than the point on *AC*. Thus *BD* crosses in front of *AC*, so that *BD* is visible in the front view and *AC* is hidden.

Auxiliary views. Figure 8 illustrates another basic principle of descriptive geometry that facilitates the discussion of auxiliary views:

II. Given two planes (*A* and *C*) perpendicular to a third plane (*B*), a point *P* projected orthogonally onto the three planes, and the rotation of *A* and *C* into *B* about their respective lines of intersection with *B* (L_A and L_C), then P^A is the same distance from L_A as P^C is from L_C.

To convey complete and correct information many views may be necessary to show every plane surface bounding the object in its true size and shape at least once. In choosing the principal views, the drafter positions the object with reference to *H* and *V* so as to have the maximum number of its surfaces parallel to *H* or *V* or *R*, a third plane perpendicular to both *H* and *V*. Orthographic projection yields the true size and shape of every such surface in the front, the top, or the side view. A surface parallel to *H* or *V* or *R*, the three principal planes, is perpendicular to the other two. Additional or auxiliary views are necessary to represent the true size and shape of other plane surfaces. A plane perpendicular to only one of the three principal planes is said to be in an inclined position; a plane not perpendicular to any of the principal planes is said to be in an oblique position.

Inclined versus oblique planes

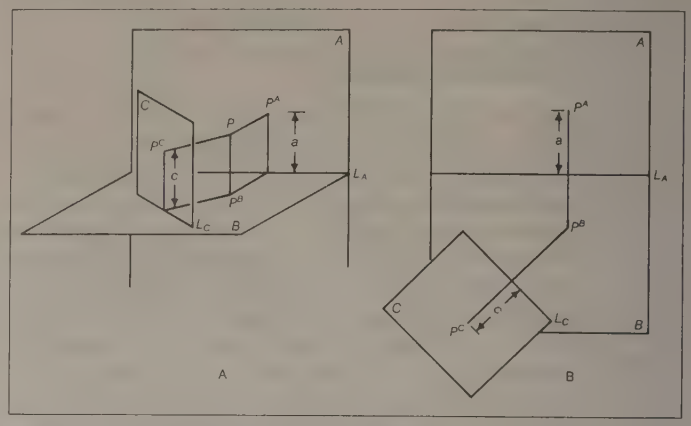

Figure 8: *Descriptive geometry, principle II (see text).* If a point is projected orthogonally onto three intersecting planes, of which two (*A* and *C*) are perpendicular to the third (*B*), and the three planes then are made to coincide, distances *a* and *c* must be equal. (A) Original arrangement of planes. (B) Planes rotated into coincidence.

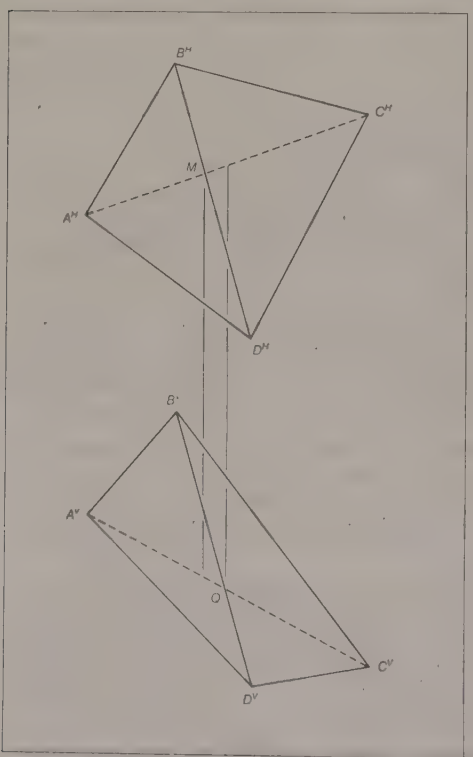

Figure 7: Identification of the hidden edge in third-angle projections of a tetrahedron (see text).

Figure 9 illustrates the application of principle II to represent the true size and shape of an inclined surface. The groove in surface *ABCD* makes an angle of 30° with a line (not shown) parallel to the edge *DC*. An auxiliary view in which *A*, *B*, *C*, and *D* are labeled with primes, obtained by projection onto a plane *P*, parallel to the surface *ABCD*, is the only one in which the true shape of *ABCD* and the true size of the 30° angle are correctly shown. The dimension indicated by the double-headed arrow is the same in the *H* (top) and auxiliary views, as required by principle II. The plane of the auxiliary view and the plane of the *H* view are perpendicular to the plane of the *V* view.

The true shape of an oblique surface can be shown correctly only on a second auxiliary view prepared by an extension of the procedure used for a first auxiliary view.

Automobile bodies, aircraft and ship hulls, and the irregular terrain of the natural site of a dam, bridge, or highway, are studied and detailed by means of contour lines on the surfaces. Three-dimensional modeling is necessary if design is highly competitive, as with automobiles, or if optimum streamlining is essential. Contour lines are projections of the intersections of the surface under study and imaginary planes at the reference locations.

Pictorial views. Although the emphasis on true descriptions of sizes and shapes requires orthographic projection for working and construction drawings, pictorial representations may be useful. In architecture, for example, the designer of the exterior of a building or the interior of an important space may be guided by perspective drawings and other pictorial representations. The construction of major projects may be preceded by the building of three-dimensional models, although these are expensive and seldom used in the early stages of design. Pictorial representations often are used for attracting investors or for advertising of new buildings and other products. Although a specialist in marketing might be intimidated by working drawings, he might grasp a pictorial representation easily enough to make useful suggestions about a design before production or construction was under way.

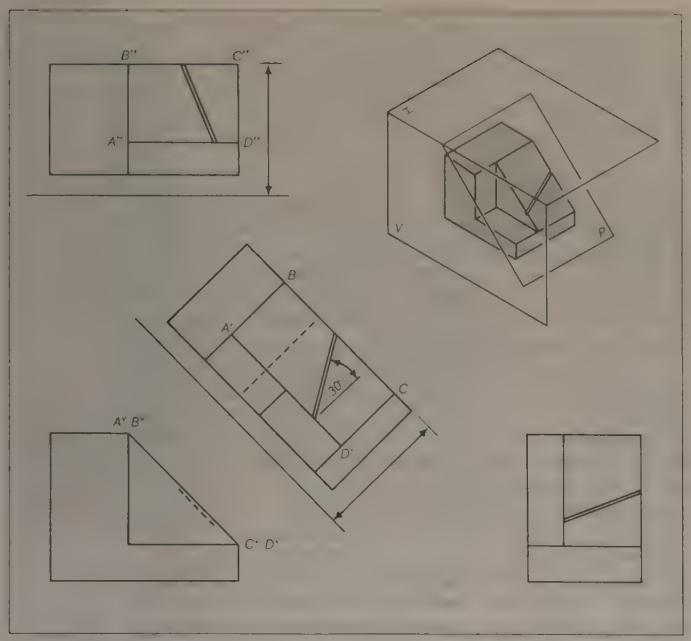

Figure 9: Use of auxiliary view to show true size and shape of an inclined surface (*ABCD*), which is not correctly represented in the front, top, or side view (see text).

The execution of a perspective drawing may require more time than is justified in the design of a small item. In many cases orthographic projection, coupled with the rotation of the object with respect to the reference planes, produces an adequate pictorial representation.

Oblique projection

Figures 2A, 2C, 3, 4A, and 5 illustrate the pictorial representation achieved by oblique projection, in which the principal surface of the object is considered to be in the plane of the paper and thus is represented in true size and shape. The angle the receding axis makes with the horizontal lines of the drawing is chosen arbitrarily but with care in terms of the clarity of the particular representation. True lengths are set off along the receding axis as an arbitrary choice. This is a convenient method for constructing a pictorial representation. Unacceptable distortion results when oblique projection is used to represent large objects or those with large dimensions or important details along the receding axis.

DRAFTING PRACTICE

Standards. The value of a set of drawings conveying the complete and correct information necessary for the execution of a project fostered the gradual standardization of practices. The widespread use of both first-angle and third-angle projection was long a major problem, but around the beginning of the 19th century a third-angle projection became the standard practice in the execution of industrial drawings in the United States. Australia followed this lead, but most industrial countries continued to follow Great Britain's use of first-angle projection. Architects in the United States and elsewhere generally use first-angle projection.

Drafting standards commonly evolve as a consensus develops among professional practitioners. Since 1917 in the United States the American National Standards Institute and its predecessors have encouraged this process and published standards for projections, various types of sections, dimensioning and tolerancing, representation of screw threads, all types of fasteners, graphic symbols for various specialties, and a great deal more. In other industrialized nations, analogous organizations—such as the British Standards Institution and the Deutsches Institut für Normung ("German Standards Institute")—function in the same way. In addition, many industrial groups and individual companies have established more detailed standards for their particular purposes.

The International Organization for Standardization, with headquarters in Geneva, coordinates global standards. International communication is hindered by the lack of agreement concerning first-angle versus third-angle projection and by the persistence in the United States of inches, feet, and other customary units for dimensioning. Economic pressures, however, are moving American industries to adopt the international metric system, SI units (Système Internationale d'Unités). The delay is related to the substantial costs of retooling and retraining. Because the strategy for correctly dimensioning a drawing is the same for all units, the rate of transition to SI units in the United States is not related to the drafting community, nor are SI units a special problem in drafting practice.

Equipment. Correct design information and projection are the imperatives of a set of engineering drawings. The skill and dexterity shown by some persons in drawing more accurately, more quickly, or more neatly have recognized value in the preparation of such drawings. Equipment has been invented to facilitate the performance of the manual tasks. Most widely known are the T square, triangle, protractor, and compass; the parallel straightedge is an alternative to the T square. The drafting machine, introduced about 1930, allows a straightedge to be moved while maintaining any desired angle between it and the edge of the drawing board. Combining the functions of the T square, triangle, protractor, and scale, it greatly increases the efficiency of producing a drawing.

Computers. A very important change in drafting procedure began in the early 1960s when programs were introduced to facilitate the composition of graphic images on the screen of a computer monitor, to retain the associated data in memory, and to retrieve the information to actuate plotting devices that produce not only the lines and arcs of an engineering drawing but also the symbols, dimension arrows, and strings of alphanumeric characters of notes and legends. Software can be prepared or purchased to perform the tasks involved in drafting: sketching of ideas to guide the design; calculation of the sizes of parts to satisfy codes, mechanical properties of materials, and machining requirements; preparation of working drawings; and production of pictorial representations. Computer-aided design (CAD) may be likened to word processing. Under direction, a word processor can correct misspellings, insert or delete words or sentences, rearrange sections of an article, or prepare accurately typed copies, but it cannot write an article. Similarly, knowledge, experience, and all but manual drawing skill are needed to produce a set of drawings with CAD, which has become increasingly important in industrial and architectural drafting.

DUPLICATION OF DRAWINGS

Blueprinting, the first economical method for duplicating drawings, was invented in 1842 and introduced in the United States in 1876. The diazo process, xerography, and computer-controlled drafting machines have more recently shared this function. The availability of numerous copies of drawings facilitated the division of labour among artisans, who formerly had worked out many details—such as exact sizes and shapes of parts, fits, and clearances—while custom building each item. The specification of these details became the duty of the designer-drafters, requiring them to refine their skills accordingly and leading to further development of the drafting profession.

BIBLIOGRAPHY. Aspects of drafting from basic instruction to industrial practices are treated in WALTER C. BROWN, *Drafting for Industry* (1974, reprinted 1984), a comprehensive treatment including coverage of CAD; PAUL WALLACH, *Metric Drafting* (1979), with emphasis on the use of the international metric system for dimensioning and tolerancing; and PAUL C. BARR *et al., CAD: Principles and Applications* (1985), which covers general-purpose CAD functions and applications to industrial practice and training. WILLIAM T. GOODBAN and JACK J. HAYSLETT, *Architectural Drawing and Planning*, 3rd ed. (1979), discusses architectural sketching and drafting, including design concepts. See also GEORGE E. ROWBOTHAM (ed.), *Engineering and Industrial Graphics Handbook* (1982).

Drawing

Drawing as formal artistic creation might be defined as the primarily linear rendition of objects in the visible world, as well as of concepts, thoughts, attitudes, emotions, and fantasies given visual form, of symbols and even of abstract forms. This definition, however, applies to all graphic arts and techniques that are characterized by an emphasis on form or shape rather than mass and colour, as in painting. Drawing as such differs from graphic printing processes in that a direct relationship exists between production and result. Drawing, in short, is the end product of a successive effort applied directly to the carrier, which is usually paper. Whereas a drawing may form the basis for reproduction or copying, it is nonetheless unique by its very nature.

Although not every artwork has been preceded by a drawing in the form of a preliminary sketch, drawing is in effect the basis of all visual arts. Often the drawing is absorbed by the completed work or destroyed in the course of completion. Thus, the usefulness of a ground plan drawing of a building that is to be erected decreases as the building goes up. Similarly, points and lines marked on a raw stone block represent auxiliary drawings for the sculpture that will be hewn out of the material. Essentially, every painting is built up of lines and pre-sketched in its main contours; only as the work proceeds is it consolidated into coloured surfaces. As shown by an increasing number of findings and investigations, drawings form the material basis of mural, panel, and book paintings. Such preliminary sketches may merely indicate the main contours or may predetermine the final execution down to exact details. They may also be mere probing sketches. Long before the appearance of actual small-scale drawing, this procedure was much used for monumental murals. With sinopia—the preliminary sketch found on a layer of its own on the wall underneath the fresco, or painting on freshly spread, moist plaster—one reaches the point at which a work that merely served as technical preparation becomes a formal drawing expressing an artistic intention.

Not until the late 14th century, however, did drawing come into its own—no longer necessarily subordinate, conceptually or materially, to another art form. Autonomous, or independent, drawings, as the name implies, are themselves the ultimate aim of an artistic effort; therefore, they are usually characterized by a pictorial structure and by precise execution down to details.

Formally, drawing offers the widest possible scope for the expression of artistic intentions. Bodies, space, depth, substantiality, and even motion can be made visible through drawing. Furthermore, because of the immediacy of its statement, drawing expresses the draftsman's personality spontaneously in the flow of the line; it is, in fact, the most personal of all artistic statements. It is thus plausible that the esteem in which drawing was held should have developed parallel to the value placed on individual artistic talent. Ever since the Renaissance, drawing has gradually been losing its anonymous and utilitarian status in the eyes of artists and the public, and its documents have been increasingly valued and collected.

This article will deal with the aesthetic characteristics, the mediums of expression, the subject matter, and the history of drawing.

This article is divided into the following sections:

General considerations

ELEMENTS AND PRINCIPLES OF DESIGN

The principal element of drawing is the line. Through practically the entire development of Western drawing, this figure, essentially abstract, not present in nature, and appearing only as a border setting of bodies, colours, or planes, has been the vehicle of a representational more or less illusionist rendition of objects. Only in very recent times has the line been conceived of as an autonomous element of form, independent of an object to be represented.

Conscious and purposeful drawing represents a considerable mental achievement, for the ability to reduce the spatial objects in the world around one to lines drawn on a plane presupposes a great gift for abstraction. The identification of the motif of a drawing by the viewer is no less an achievement, although it is mastered by practically all human beings. The visual interpretation of a line as a representation of a given object is made possible through certain forms of that line that call forth associations. The angular meeting of two lines, for example, may be considered as representing the borders of a plane; the addition of a third line can suggest the idea of a cubic body. Vaulting lines stand for arches, convergent lines for depth.

With the aid of this modest basic vocabulary, one can distill comprehensible images from a variety of linear phenomena. The simple outline sketch—Greek legend has it that the first "picture" originated from copying the shadows on the sand—represents one of the oldest and most popular possibilities of graphic rendition. After decisively characterizing the form of Egyptian drawing and the archaic art of Greece, the outline sketch became the chief vehicle of artistic communication in late antiquity and the Middle Ages. Used in a variety of ways in the early Renaissance, it became dominant once again in Neoclassicism, as it is, for that matter, in the classicist period of a given artist's total work.

The outline sketch

The outline sketch is elaborated into the detailed drawing by means of the line, which differentiates between the plastic and the spatial values of the object. Borders of individual objects, changes in the spatial plane, and varying intensities of colour applied within an outline sketch all tend to enrich and clarify the relationship between the whole and its component parts.

The free beginning, the disappearance, or the interruption of a line provides opportunities for gradually slurring an edge until it becomes a plane, for letting colour transitions fade away, for having the line vanish in the depth.

The thickening or thinning of a line can also be used to indicate, spatially or by means of colour, a change in

the object designated by that line. Even light-and-shadow values may be rendered by differences in stroke strength.

While the chopping up of a line into several brief segments, and, even more, the drawing of individual lines running parallel in one direction, makes the outlined form appear less corporeal and firm, it reproduces the visual impact of the form in a more pictorial manner. Slight shifts in the flow of the line are intended to represent smooth curves and transitions; they also reinforce the effect of light striking a surface and thus give the corporeal appearance. Finally, short, curving segments of a line that do not stand in a clearly angular relationship to one another but are arranged on the sheet in loose formation allow the pictorial and colour component to dominate, as in the work of the 16th-century Italian artist Jacopo Tintoretto. An extreme case is the complete dissolution of the linear stroke into dots and spots, as, for example, in the drawings of the 19th-century Pointillist painter Georges Seurat.

A mere combination of these varied shapes of the line, without reference to the mediums in which the lines are drawn, provides the artist with a plethora of subjective opportunities for the expression both of general stylistic traits and of personal characteristics. An arrangement of forceful, mainly straight strokes in accentuated, sharp angles lends the drawing an austere character emphasizing

Loose use of line emphasizing pictorial effect, study after Michelangelo's "Day," by Jacopo Tintoretto (c. 1518–94), black and white chalk on blue paper. In the Metropolitan Museum of Art, New York. 34.9 × 50.5 cm.

dramatic and expressive traits. This method of drawing, in fact, is characteristic of stylistic epochs and artistic regions (not to mention individual artists) that prefer these qualities: in the rather sober city of Florence, in German Expressionism, where it is used to convey mood, but also in the drawings of Rembrandt and Vincent van Gogh. Soft lines, on the other hand, running in drawn-out, smoothly rounded forms and stressing graphic regularity above any statement of content, constitute the formal equivalent to elegant, courtly, and lyric qualities of expression. Accordingly, they are often found in drawings of the Soft style; in the early Renaissance, particularly in the work of artists from the Italian province of Umbria and in young Raphael's sketches; in the work of Nazarenes, a 19th-century group of Romantic painters whose subjects were mainly religious; in the Jugendstil, a late-19th- and early-20th-century German decorative style parallel to Art Nouveau in its organic foliate forms, sinuous lines, and non-geometric curves; and in a very pure form in one of the classic draftsmen, the 19th-century French painter Jean-Auguste-Dominique Ingres. A markedly even-stroke texture, with waxing and waning strokes in regular proportions and evenly distributed within the page, brings drawing close to calligraphic writing and is found in all stylistic epochs that value ornamentation.

Hatching and cross-hatching

The technique of hatching gives the line an additional potential for the clarification of plastic relationships and of light phenomena. In hatching, parallel, short, equidistant, more or less straight lines create static and tectonic (structural) values by marking individual body planes. Gently curved hatching stresses the roundness of the body and can also accentuate, as tone value, shaded parts of the representation.

Cross-hatching, in which two layers of hatching intersect at right angles, reinforces the body-and-shadow effect. Known since the days of Michelangelo and Dürer in the 15th and 16th centuries, this artistic technique is often used with slanted or even curved hachures for the linear rendition of rounded parts. In rigorously monotone drawings, this method is the most suitable for the depiction of spherical bodies. The human body, with its highly articulated surface, can be modelled in this fashion very clearly and precisely. For 17th- and 18th-century engravers, this process became the most important means of drawing. All of these different possibilities of linear rendition can be achieved with pen and crayon as well as with the brush.

Plane techniques. Linear techniques of drawing are supplemented by plane methods, which can also be carried out with crayon. For example, evenly applied dotting, which is better done with soft mediums (see *Surfaces, mediums, and techniques* below), results in an areal effect in uniform tone. Various values of the chiaroscuro (pictorial representation in terms of light and shade without regard to colour) scale can also be rendered by means of dry or moist rubbing. Pulverized drawing materials that are rubbed into the drawing surface result in evenly toned areas that serve both as a closed foundation for linear drawing and as indication of colour values for individual sections.

More significant for plane phenomena, however, is brushwork, which, to be sure, can adopt all linear drawing methods but the particular strength of which lies in stroke width and tone intensity, a medium that allows for extensive differentiation in colour tone and value. Emphases created by the repeated application of the same tone provide illusionistic indentations that can be conceived of spatially and corporeally. Colour differences result from the use of various mediums. Brushwork also lends itself to spatial and plastic representation, just as it can constitute an autonomous value in nonrepresentational drawings.

All of these effects of monochrome drawing are accentuated with the use of varicoloured mediums of a basic material; for example, coloured chalks, drawing inks, or watercolour. While these mediums enrich the art of drawing, they do not widen its basic range.

The drawing surface. To these graphic elements must be added another phenomenon the formal significance of which is restricted to drawing: the effect of the unmarked drawing surface, usually paper. Almost all studies (draw-

Hard style, "View of Arles," by Vincent van Gogh, China ink with reed pen and wash, 1888. In the Museum of Art, Rhode Island School of Design, Providence. 43.3 × 54.9 cm.

By courtesy of the Museum of Art, Rhode Island School of Design, Providence

ings of details), many autonomous sheets, most portrait drawings, as well as figure compositions, still lifes, and even landscapes stand free on the sheet instead of being closed off with a frame-line. Thus, the empty surface, suggesting by itself a spatial background to the drawing on it, contributes actively to the artistic effect.

Details conveyed by empty space

Even within line composition, the surface left blank fulfills an essential role as a representational value defined by the drawn statements surrounding it as body of a given substantiality or space of a given expanse. Among the details conveyed by the empty space may be the planes of a face, the smooth width of a garment, the mass of a figure or object, the substance the borders and nuances of which are indicated by the drawing. Even the space around individual objects, the spatial distance between them and their environment, the width of a river and the depth of a landscape may be merely signalled by the drawing and filled by the void.

This void can itself become the dominant form enclosed by lines or contours—for example, in decorative sketches and in many ornamental drawings that make use of the negative form, an effect attainable also by tinting the blank planes.

Relationship between drawing and other art forms. The bond between drawing and other art forms is of course very close, because the preliminary sketch was for a long time the chief purpose of the drawing. A state of mutual dependence exists in particular between painting and drawing, above all, in the case of sketches and studies for the composition of a picture. The relationship is closest with preliminary sketches of the same size as the original, the so-called cartoons whose contours were pressed through or perforated for dyeing with charcoal dust. Once transferred to the painting surface, the sketch had served its purpose.

On autonomous sheets, too, the close connection between drawing and painting is evidenced by the stylistic features that are common to both. Drawing and painting agree in many details of content and form. Measurements; proportions of figures; relationship of figure to surrounding space; the distribution of the theme within the composition according to static order, symmetry, and equilibrium of the masses or according to dynamic contrasts, eccentric vanishing points, and overaccentuation of individual elements; rhythmic order in separate pictorial units in contrast to continuous flow of lines—all of these formal criteria apply to both art forms. The uniform stylistic character shared by drawing and painting is often less severely expressed in the former because of the spontaneous flow of the unfettered artist's stroke, or "handwriting," and of the struggle for form as recorded in the pentimenti (indications in the drawing that the artist had changed his mind and drawn over his original formulation). Furthermore drawing can stimulate certain aspects of movement more easily than painting can through the rhythmic repetition of a contour or the blended rubbing of a sharp borderline.

Still closer, perhaps, is the bond between drawing and engraving, which works with the same artistic means, with monochrome linearity as its main formal element and with various tone and plane methods closely related to those of drawing.

Drawing is more independent than sculpture because sculpture uses a three-dimensional model. As a result, sculptors' drawings can always claim a greater degree of autonomy. (For the special position of the architectural sketch, see *Subject matter of drawing* below.)

SURFACES, MEDIUMS, AND TECHNIQUES

Types of ground. One can draw on practically anything that has a plane surface (it does not have to be level); for example, papyrus and parchment, cloth, wood, metals, ceramics, and even walls, glass, and sand. (With some of these, to be sure, another dimension is introduced through indentations that give the visual effect of lines.) Ever since the 15th century, however, paper has been by far the most popular ground.

Paper manufacturing

The technique of paper manufacturing, introduced from East Asia by the Arabs, has remained virtually unchanged for the past 2,000 years. A fibrous pulp of mulberry bark, hemp, bast, and linen rags is drained, pressed, and dried in flat molds. The introduction of wood pulp in the mid-19th century, which enabled manufacturers to satisfy the enormously increased demand for bulk paper, did not affect art paper because paper of large wood content yellows quickly and is therefore ill-suited for art drawing. The essential preparation of the paper to give it a smooth and even surface for writing or drawing was once done by rubbing it with bone meal, gypsum chalk, or zinc and titanium white in a very thin solution of glue and gum arabic. The proper priming, achieved through repeated rubbing and polishing, was of the utmost importance, especially for metalpoint drawings. If such preparation is too weak, the paper accepts the stroke badly; if it is too strong, the coating cracks and chips under the pressure of the hand. Since the early 15th century, however, the sheets have been given the desired smooth and nonabsorbent consistency by dipping them in a glue or alum bath. The addition of glue also made it possible to impart to the pulp paper a quality that permitted pen drawings. Pigments, too, could of course be added to the pulp, and the so-called natu-

ral papers—chiefly blue and called Venetian papers after the centre of the retail trade in this commodity—became more and more popular. While the 17th century liked half tints of blue, gray, brown, and green, the 18th preferred warm colours such as ivory and beige, along with blue. Since the 18th century, paper has been manufactured in all conceivable colours and half tones.

The range of quality has also greatly increased since the end of the 18th century to give more painstakingly produced drawing papers. Even in earlier times, the absorbent Japan paper made of mulberry bark enjoyed great popularity. Handmade paper, stronger and free of wood, with an irregular edge, has remained to this day a favourite surface for drawings. Vellum, delicate and without veins, resembles parchment in its smooth surface. Modern watercolour paper is a pure linen paper glued in bulk and absolutely free of fat and alum; its two surfaces are of different grain. For pastel drawings, a firm, slightly rough surface is indicated, whereas pen drawings are best done on a very smooth paper.

Granulated and softer drawing tools, such as charcoal, chalk, and graphite are not as dependent on a particular type of paper; but, because of their slight adhesiveness, they often require a stronger bond with the foundation as well as some form of surface protection. This process of fixing was formerly done through repeated varnishing with gum-arabic solution and even with glue or egg-white emulsion. Modern siccatives (drying substances) inhibit discoloration but cannot prevent the living surface from appearing sealed, as it were, under a skin. In pastels especially, the manifold prismatic effects of finely powdered coloured crayons are thus lost, and the bright and airy surface is turned into an amorphous, heavy layer. Pastels, which brush off easily, are therefore best preserved under glass.

Tools and techniques. Such varied tools as slate pencils, charcoal, metal styli, and chalks may be used for drawing as well as all writing utensils, including pens, pencils, and brushes; indeed, even chisels and diamonds are used for drawing. Dry drawing tools differ in effectiveness from liquid ones because it is not irrelevant from the artistic point of view whether one uses a self-drawing medium that permits an evenly flowing line dependent only on hand pressure or a transferring tool that must be put down periodically and refilled, with resultant differences in the strength and concentration of the line. Modern drawing mediums that combine both possibilities, such as fountain pens, ball-point pens, and felt pencils, are recent inventions.

Dry and liquid drawing tools

No less varied than the nature and composition of these drawing mediums is their aesthetic effect. It would nevertheless be wrong to systematize the art of drawing on the basis of the techniques applied; not only does almost every technique have several applications but it can also be combined with other techniques, and the draftsman's temperament inevitably plays a role as well. Even if certain techniques predominate in certain periods, the selection of drawing mediums depends on the intended effect and not vice versa. Artists have always been able to attain the desired effect with a variety of techniques. Dry mediums, for example, are predestined for clear lines, liquid ones for plane application. Yet extremely fine strokes can also be made by brush, and broad fields can be marked in with pencil or crayon. Some mediums, including charcoal, one of the oldest, if not the oldest of all, allow both extremes.

Charcoal. In every hearth or fireplace, partially consumed pieces of wood remain that can be used as a convenient tool for drawing. Evidence of charcoal sketches for mural, panel, and even miniature paintings can still occasionally be seen under the pigment. Drawing charcoal produced from wood that is as homogeneous as possible gives a porous and not very adhesive stroke. The pointed charcoal pencil permits hair-thin lines; if used broadside on the surface, it creates evenly toned planes. Rubbing and pulverizing the charcoal line results in dimmed intermediate shades and delicate transitions. Because of its slight adhesiveness, charcoal is eminently suited to corrective sketching; but if the drawing is to be preserved, it must be protected by a fixative.

As a medium for quick, probing sketches and practice in studying models, charcoal was once much used in all academies and workshops. The rapid notation of difficult poses, such as Tintoretto demanded of his models, could be done quickly and easily with the adaptable charcoal pencil. While some of these sheets were deemed worthy of preservation, hundreds have surely been lost.

Charcoal used for portraits

Charcoal has often been used for portrait drawings to preserve for the eventual painting pictorial tints that were already present in the preliminary sketch. When destined to be autonomous portraits, charcoal drawings are executed in detail; with their sharp accents and delicate modelling, such portraits cover the whole range of the medium. In "Portrait of a Lady," by the 19th-century French painter Édouard Manet, the grain of the wood in the chair, the fur trimming on the dress, the compactness of the coiffure, and the softness of the flesh are all rendered in the same material: charcoal. Popular as that material was for studies and sketches, it has been used for independent drawings destined for preservation by only a few artists; for example, the 17th-century Dutch painter Paulus Potter. It is somewhat more frequent among the great draftsmen of the 19th and 20th centuries, such as Edgar Degas, Henri de Toulouse-Lautrec, Käthe Kollwitz, and Ernst Barlach.

Oiled charcoal, with the charcoal pencils dipped in linseed oil, provides better adhesion and a deeper black. Used in the 16th century by Tintoretto, this technique was applied above all by the Dutch draftsmen of the 17th century in order to set deep-black accents. The advantage of better adhesion in the indentations of the paper in contrast to dry charcoal, which sticks to the elevations, has to be paid for, however, by "incorrigibility"; *i.e.*, correction cannot be made. In addition, charcoal crayons that have been deeply dipped in oil show a brownish streak left by the oil alongside the lines.

Chalks. The chalks, which resemble charcoal pencils in outward appearance, are an equally important drawing medium. If charcoal was primarily a medium for quick sketching that could be corrected and for the search for artistic form, chalk drawing, which can also fulfill all of these functions, has steadily gained in importance as an autonomous vehicle of expression. Since the end of the 15th century, stone chalk, as found in nature, has become increasingly more significant in art drawing. As a basic material, alumina chalk has various degrees of hardness,

so that the stroke varies from slightly granular to homogeneously dense and smooth.

The attempt to produce a crayon or pencil of the greatest possible uniformity has led to the production of special chalks for drawing; that is, chalks, which, after being pulverized, washed, and molded into convenient sticks, allow a softer and more regular stroke and are also free of sandy particles. The admixture of pigments (carbons in the case of black chalks) creates various tints from a rich black to a brownish gray; compared to the much-used black chalk, the brown variety is of little significance. White chalk, also found in nature, is rarely employed as an independent medium for drawing, although it is frequently used in combination with other mediums in order to achieve reflections of light as individual accents of plastic modelling.

Beginning with the 15th century, chalk has been used increasingly for studies and sketches. Its suitability for drawing exact lines of any given width and also for laying on finely shaded tints makes it particularly appropriate for modelling studies. Accents that stress plastic phenomena are applied by varying the pressure of the hand. Characteristic details in portrait drawings in particular can be brought out in this manner. Pictorial values as well as light and shadow effects can be rendered with chalk without losing their firm, plastic form. For the same reason, chalk is also most valuable in sketching out paintings and indicating their values.

All of these qualities explain why chalk is such a good medium for autonomous drawings. Indeed, there is scarcely a draftsman who has not worked in chalk, often in combination with other mediums. Aside from portrait drawings done all over the world, landscapes have formed the main theme of chalk drawings, especially with the Dutch, in whose art landscape drawings have played a large role. Ever since the invention of artificial chalk made of lampblack (a fine, bulky, dull-black soot deposited in incomplete combustion of carbonaceous materials), which possesses a precisely measurable consistency—an invention ascribed to Leonardo da Vinci—the pictorial qualities of chalk drawing have been fully utilized. Chalks range from those that are dry and charcoal-like to the fatty ones used by lithographers.

Use of sanguine

Another very important drawing pencil is similarly a chalk product: the red pencil, or sanguine, which contains ferric oxide, which occurs in nature in shadings from dark brown to strong red and can also be manufactured from the same aluminum-oxide base with ferric oxide or rust added. Besides the stronger pictorial effect possible because of its chromatic value, sanguine also possesses a greater suppleness and solubility in water. Thus, a homogeneous plane can be created through moist rubbing, a compact stroke through liquid linear application, a very delicate tone through light wiping. Although this oxide was used for red tints in prehistoric painting, sanguine does not seem to have acquired artistic dignity until the 15th century, when it became customary to fix drawings by painting them over with a gum solution, for sanguine has no more adhesiveness than charcoal. In the 15th century, sanguine was a popular drawing medium because of its wealth of pictorial possibilities. Those inclined to be colorists—such as the portraitists Jean Clouet and Hans Holbein, the Flemish painters around Peter Paul Rubens, and, above all, the French artists of the 18th century—particularly favoured it. The possibilities of sanguine range from suggestive forms with markedly plastic values to a very pictorial, soft rendition of visual surface stimuli.

A combination of various chalks offers still richer coloristic possibilities. Black chalk and sanguine have been widely used since the 16th century to achieve colour differentiation between flesh tones, hair, and the material of garments. The combination of black and white chalk serves plastic modelling, as does that of the softer sanguine with white chalk; in the former case, the accentuation rests with the black, in the latter, with the more suggestive delineation in white.

A decidedly coloristic method lies in the combination of various chalk colours with one another and with tinted paper. Such pictorially executed sheets, called *à deux crayons* (with two colours) and *à trois crayons* (with three colours), respectively, were especially popular in 17th- and 18th-century France. Antoine Watteau reached a previously unheard of harmony of different chalks on natural paper. With the three colours, Nicolas Lancret, Jean-Étienne Liotard, Jacques-André Portail, François Boucher—to name but a few such artists—achieved sensitive drawings that are very appealing coloristically.

Pastel crayons

An additional colour refinement is made possible with pastel crayons. An ample selection of dry colour pigments in pastel crayons, prepared with a minimum of agglutinants and compounded with different shades of white for the articulation of tints, is commercially available. The colours can be laid on in linear technique directly with the crayons, but an area application made with a piece of soft suede or directly, with the fingers, is more frequent. Although this technique was known to the Accademia degli Incamminati (to the painter Guido Reni, for example) as early as the 17th century, it did not reach its flowering until the 18th century, especially in France (with Jean-Marc Nattier and Jean-Baptiste-Siméon Chardin) and in Venice (with Rosalba Carriera). Pastel chalks are particularly favoured for portraits; their effect approximates that of colour-and-area painting rather than line drawing.

In the 19th and 20th centuries, Degas reverted to a stronger accentuation of the delineatory aspects of drawing. With intermediate varnishes he achieved an overlay drawing with different colours and thus an increased emphasis on individual strokes. This technique, fundamentally different from the older one, was imitated with minor variations by Odilon Redon, Gustave Moreau, Jean-Édouard Vuillard, Pierre Bonnard, and others. It has also been borrowed by such Expressionist artists as Edvard Munch and Ernst Ludwig Kirchner.

Modern grease chalks offer a chromatic scale of similar range. Developed originally for such technical purposes as the lettering of very smooth surfaces, such as metal or glass, they can be applied in the same flat manner as pastels, although with the opposite aesthetic effect: that of compact colours. It was the 20th-century English sculptor Henry Moore who first and convincingly exploited the feasibility of continuing, with other mediums, such as pen or watercolour, work on the firm surface that had been led out with grease chalks.

Metalpoints. Metalpoints have been used for writing and delineation ever since the scriptoria of antiquity. It required little imagination to employ them also in drawing. The most frequently used material was soft lead, which on a smooth surface comes out pale gray, not very strong in colour, and easily erasable but very suitable for preliminary sketches. Aside from lead, tin and copper were also used, as well as sundry lead-and-pewter alloys. The 15th-century Venetian painter Jacopo Bellini's book of sketches in London with leadpoint drawings on tinted paper is a particularly valuable example of this technique, even if individual portions and, indeed, entire pages that had become effected were drawn over long ago. One can see little more than the traces left by the pencil because, as in many other metalpoint drawings, the sketches were redrawn in another medium. Botticelli, for example, sketched with a leadpoint the outline of his illustrations to Dante's *Divine Comedy*, retracing them afterward with the pen. Metalpoints were used into the 18th century for perspectivist constructions and auxiliary delineation, especially in architectural drawings.

Silverpoint drawing

More suited to permanent drawing is the silverpoint, which requires special preparation of the foundation and, once applied, cannot be corrected. Its stroke, also pale gray, oxidizes into brown and adheres unerasably. Silverpoint drawings accordingly require a clearer concept of form and a steady hand because corrections remain visible. Because too much pressure can bring about cracks in the foundation, the strokes must be even; emphases, modelling, and light phenomena must be rendered either by means of dense hachures, repetitions, and blanks or else supplemented by other mediums. Despite these difficulties, silverpoint was much used in the 15th and 16th centuries. Dürer's notebook on a journey to Holland shows landscapes, portraits, and various objects that interested him drawn in this demanding technique. Silverpoint was

much in demand for portrait drawings from the 15th into the 17th century; revived in the 18th-century Romantic era, it is still occasionally used by modern artists.

Graphite point. Toward the end of the 16th century, a new drawing medium was introduced and soon completely displaced metalpoint in sketching and preliminary drawing: the graphite point. Also called Spanish lead after its chief place of origin, this drawing medium was quickly and widely adopted; but because of its soft and smeary consistency it was used for autonomous drawings only by some Dutch painters, and even they employed it mostly in conjunction with other points. (It might be added that the graphite point was originally taken for a metal because its texture shines metallically in slanting light.) The lead pencil, or more properly *crayon Conté,* became established in art drawing after Nicolas-Jacques Conté invented, around 1790, a manufacturing process similar to that used in the production of artificial chalk. Purified and washed, graphite could henceforth be made with varying admixtures of clay and in any desired degree of hardness. The hard points, with their durable, clear, and thin stroke layers, were especially suited to the purposes of Neoclassicist and Romantic draftsmen. The Germans working in Rome, in particular, took advantage of the chance to sketch rapidly and to reproduce, in one and the same medium, subtle differentiations as well as clear proportions of plasticity and light. Among the most masterful pencil artists of all was Ingres, who presketched systematically in pencil the well-thought-out structure of his paintings.

The more pictorially inclined artists of the late 19th century, such as Ferdinand Delacroix, preferred softer pencils in order to throw into plastic relief certain areas within the drawing. Seurat, on the other hand, reached back to graphite in his drawings from the concert cafés, among them "Au concert européen" (Museum of Modern Art, New York) in which he translated the Pointillistic technique (applying dots of colour to a surface so that from a distance they blend together) into the monochrome element of drawing. Pencil frottage (rubbing made on paper laid over a rough surface), first executed by the Surrealist artist Max Ernst, represents a marginal kind of drawing, for here the artist's hand is no longer the sole creator of forms.

Pencil frottage

Coloured crayons. Coloured crayons, in circulation since the late 19th century, offer all the possibilities of black graphite points; and, in combinations, they attain a stronger colour value than chalks because they do not merge with one another. Every line preserves its original and characteristic colour, a form of independence that Gustav Klimt and Picasso exploited to the full.

Incised drawing. A role apart is that played by incised drawings. Their pronounced linearity gives them the visual appearance of other drawings; materially, however, they represent the opposite principle, that of subtracting from a surface rather than adding to it. Incised drawings are among the oldest documents of human activity. In primitive African cultures, the methods and forms of prehistoric bone and rock drawings have survived into the present. In a decorative and conceivably also symbolic form, incised decorations on pottery have existed for thousands of years; insofar as the comparison is valid, they correspond in every formal respect to applied drawings of the same period. A formal equivalent may also be observed in later times: in the decorative details of implements, especially metal—from the drawings on Greek mirrors, through the jewelry made at the end of the Roman Empire, to the scenes on medieval weapons and, above all, on Renaissance dress armour. More often than not these are drawings that follow certain models rather than free drawings in the sense of sketches.

Logically, one would also have to consider all niello work under the heading of drawing, because the picture in this case is cut out of the metal and filled with a deep black-coloured paste so that it appears to the eye as a linear projection on a plane. In like manner, work with the graver or burin (cutting tools) and with the etching needle on the engraving plate may be considered to parallel in its execution that gradual effort applied directly to the carrier that was defined earlier as the art of drawing. The difference lies in the fact that this work is not a goal in itself but the prerequisite for a printing process that is intended to be repetitive.

Brush, pen, and dyestuffs. Of the many possibilities of

transferring liquid dyestuffs onto a plane, two have become particularly significant for art drawing: brush and pen. To be sure, finger painting, as found in prehistoric cave paintings, has occasionally been practiced since the late Renaissance and increasingly so in more recent times. For drawing as such, however, the method is irrelevant. Similarly, the use of pieces of fur, frayed pieces of wood, bundles of straw, and the like is more significant as a first step toward the camel's-hair brush than as indication that these objects were ever drawing mediums in their own right. Although it is antedated by the brush, which in some cultures (East Asia, for example) has remained in continued use, the pen has been the favorite writing and drawing tool ever since classical antiquity.

The principle of transferring dyestuffs with the pen has remained virtually unchanged for thousands of years. The capillary effect of the split tip, cut at a slant, applies the drawing fluid to the surface (parchment, papyrus, and, since the late Middle Ages, almost exclusively paper) in amounts varying with the saturation of the pen and the pressure exerted by the drawing hand. The oldest form

The reed pen

is that of the reed pen; cut from papyrus plants, sedge, or bamboo, it stores a reservoir of fluid in its hollow interior. Its stroke—characteristically powerful, hard, and occasionally forked as a result of stronger pressure being applied to the split tip—became a popular medium of artistic expression only with the rise of a subjective view of the artist's personality during the Renaissance. Rembrandt made superb use of the strong, plastic accents of the reed pen, supplementing it as a rule with other pens or brushes. Beginning in the 19th century with the Dutch artist van Gogh, pure reed-pen drawings with a certain forcefulness of expression have been created by many artists. Expressionists such as George Grosz used the reed pen frequently.

If the selection of the reed pen already implies a formal statement of sorts, that of the quill pen opens up a far wider range of possibilities. Ever since the rise of drawing in Western art—that is, since the late Middle Ages—the quill has been the most frequently used instrument for applying liquid mediums to the drawing surface. The importance accorded to this tool is attested by the detailed instructions in painters' manuals about the fashioning of the pen from wing shafts of geese, swans, and even ravens. The supple tip of the quill, available in varying strengths,

permits a relatively wide scale of individual strokes—from soft, thin lines, such as those used in preliminary sketches for illustrations in illuminated books, through waxing and waning lines that allow differentiation within the stroke, to energetic, broad lines. It was only when metal pens began to be made of high-grade steel and in different strengths that they became a drawing implement able to satisfy the demands made by the individual artist's hand.

Although all dyestuffs of low viscosity lend themselves to pen drawing, the various inks are most often employed. The manufacture of gallnut ink had been known from the medieval scriptoria (copying rooms set apart for scribes in monasteries). An extract of gallnuts mixed with iron vitriol and thickened with gum-arabic solution produces a writing fluid that comes from the pen black, with a strong hint of purple violet, and dries almost black. In the course of time it turns a darkish brown, so that the writing fluid in old manuscripts and drawings cannot always be identified by the colour alone. In contrast to other brown writing fluids, the more strongly coloured parts of gallnut ink remain markedly darker; and because inks of especially great vitriol content decompose the paper, the drawing, particularly in its more coloured portions, tends to shine through on the reverse side of the sheet. Only industrially produced chemical inks possess the necessary ion balance to forestall this undesirable effect.

Another ink, one that seems to have found no favour as a writing fluid but has nonetheless had a certain popularity in drawing, is bistre, an easily dissolved, light-to-dark-brown transparent pigment obtained from the soot of the lampblack that coats wood-burning chimneys. Its shade depends both on the concentration and on the kind of wood from which it is derived, hardwoods (especially oaks) producing a darker shade than conifers, such as pine. During the pictorially oriented Baroque period, in the 17th and early 18th centuries, the warm tone that can be thinned at will made bistre a popular medium with which to supplement the planes of a pen drawing.

Chinese or India ink

Also derived from a carbon base is India ink, made from the soot of exceptionally hard woods, such as olive or grape vines, or from the fatty lampblack of the oil flame, with gum-arabic mixed in as a binding agent. This deep-black, thick fluid preserves its dark tone for a long time and can be thinned with water until it becomes a light gray. Pressed into sticks or bars, it was sold under the name of Chinese ink or India ink. This writing fluid, known already in Egypt and used to this day in China and India, has been manufactured in Europe since the 15th century. Favoured in particular by German and Dutch draftsmen because of its strong colour, it lent itself above all to drawing on tinted paper. Since the 19th century, India ink has been the most popular drawing ink for pen drawings, replacing all other dyestuffs in technical sketches. Only very recently have writing inks gained some significance in art drawing—in connection with the practical fountain pen.

For a relatively short time, a dyestuff of animal origin, sepia, obtained from the pigment of the cuttlefish, was used for drawing. Known since Roman times, it did not come into general use until the 18th century. Compared to yellowish bistre, it has a cooler and darker tone, and is brown with a trace of violet. Until the 18th century, it was employed by such amateur painters as the poet Goethe because of its effectiveness in depth; as a primary pigment, however, it has been completely replaced by industrially manufactured watercolours.

Other dyestuffs are of only minor importance compared with these inks, which are primarily used for pen drawings. Minium (red lead) was used in the medieval scriptoria for the decoration of initial letters and also in illustrated pen drawings. Chinese white is easier to apply with a pointed brush because of its thickness; other pigments, among them indigo and green copper sulphate, are rarely found in drawings. For them, too, the brush is a better tool than the pen. The systematically produced watercolours of various shades are almost wholly restricted to technical drawings.

In combination with written texts, pen drawings are among the oldest artistic documents. Already in classical times, texts were illustrated with firm contours and sparse interior details. During the Middle Ages, marginal

drawings and book illustrations were time and again presketched, if not definitively executed, with the pen. In book painting, decidedly delineatory styles developed in which the brush was also employed in the manner of a pen drawing: for example, in the Carolingian school of Reims, which produced the Utrecht Psalter in the 9th century, and also in southern Germany, where a separate illustrative form with line drawings was widespread with the *Biblia Pauperum* ("Poor People's Bibles," biblical picture books used to instruct large numbers of people in the Christian faith). The thin-lined outline sketch is also characteristic of the earliest individual drawings of the late Middle Ages and early Renaissance. Sketches after ancient sculptures or after nature as well as compositions dealing with familiar motifs form the main themes of these drawings. Such sheets were primarily used as models for paintings; gathered in sketchbooks, they were often handed on from one generation to the next. The practical usefulness of these drawings is attested by the supplements added to them by younger artists and by the fact that many metalpoint drawings that had become hard to decipher were redrawn with the pen, as shown by the sketchbooks of the 15th-century Italian artist Antonio Pisanello, now broken up and preserved in several different collections.

Use of sketchbooks

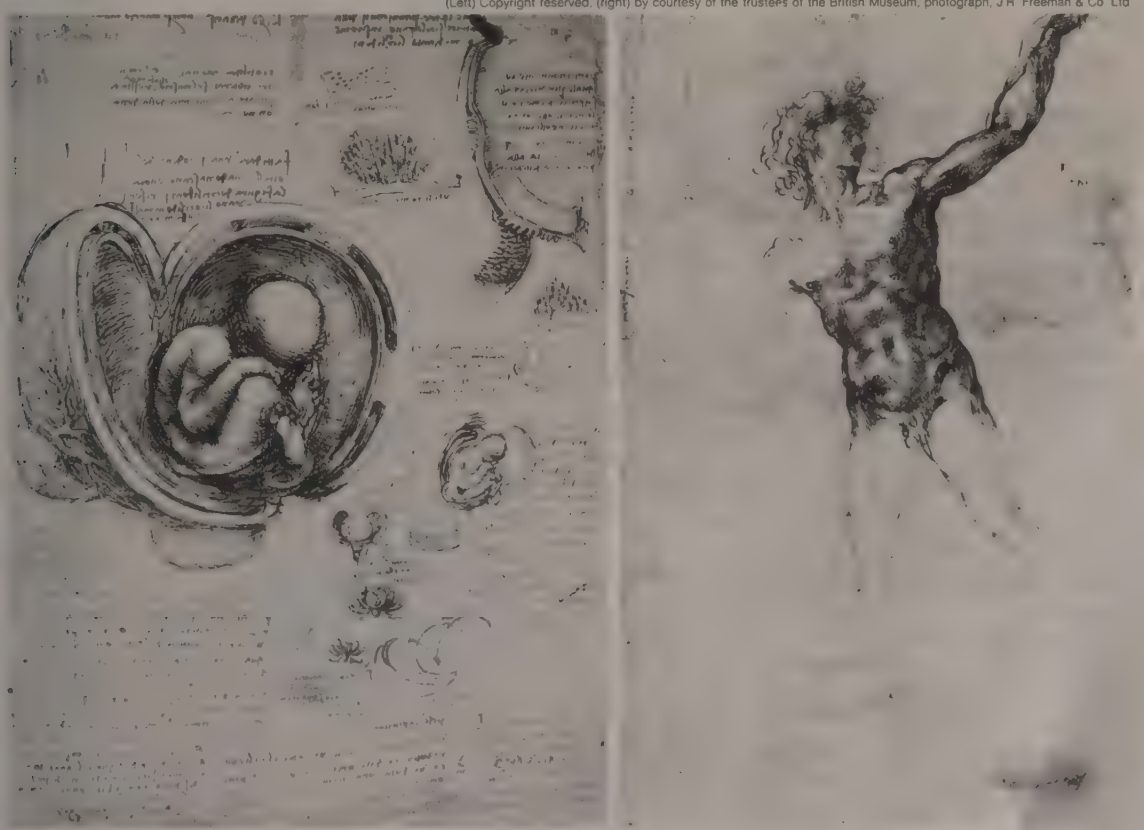
In the 16th century, the artistic range of the pen drawing reached an individual articulation that it hardly ever attained again. Every artist was free to exploit with the pen the formal possibilities that corresponded to his talents. Thus Leonardo used a precise stroke for his scientific drawings; Raphael produced relaxed sketches, in which he probed for forms and variations of form; Michelangelo drew with short strokes reminiscent of chisel work; Titian contrasted light and dark by means of hachures laid broadly over the completed figures. Among the Northerners, Dürer mastered all the possibilities of pen drawing, from quick notation to the painstakingly executed autonomous drawing, ranging from a purely graphic and delineatory technique to a spatial and plastic modelling one; it is no wonder that he stimulated so many other artists. The subjective attitude of the later 16th century is often expressed more clearly in Mannerist drawings—characterized by spatial incongruity and excessive elongation of the human figures, which are as revelatory of the artist's personality as handwriting—than it is in completed works of painting and sculpture. A special form of exact drawing is found in models for engravings; some of these were directly mounted on the wood block; some anticipate the style of the copperplate engraving in the pen-drawing stage, with waxing and waning lines, delicate stroke layers, and cross-hatching for spatial and plastic effects.

In the 17th century, the pen drawing took second place to combined techniques, especially wash, a sweep or splash of colour, applied with the brush. An open style of drawing that merely hints at contours, along with contrasting thin and powerful strokes, endowed the line itself with expressive qualities. In his numerous drawings, Rembrandt in particular achieved an exceedingly subtle plastic characterization and even light values through the differentiation of stroke layers and the combination of various pens and brushes.

Additional techniques came to the fore in the 18th century, with the pen sketch providing the scaffold for the drawing that was carried out in a pictorial style. Only decorative sketches and practical studies were laid out more often as linear drawings.

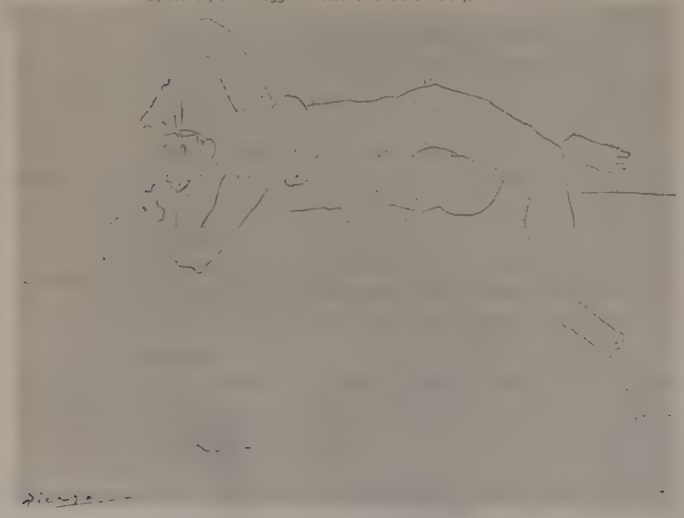
The closed, thin-contour drawing regained its importance with Neoclassicism at the end of the 18th century. The Nazarenes (the nickname of the Lucas Brotherhood—later Guild of St. Luke, who lived in monastic style) and Romantics consciously referred to the early Renaissance manner of drawing, modelling with thin lines. With closed contours, carefully set hair-and-shadow strokes, and precise parallel hachures, they attained plastic values by purely graphic means.

This technique was again followed by a more pictorially oriented phase, culminating in the late 19th century in



Individual expression in pen drawing of the Renaissance.
(Left) "Foetus in Utero," scientific drawing by Leonardo, pen and ink with red chalk, *c.* 1510–12. In the Royal Library, Windsor Castle. 30.1 × 21.4 cm. (Right) "Running Youth with Left Arm Extended," study for a sculpture by Michelangelo, pen and brown ink, *c.* 1504. In the British Museum. 37.5 × 22.9 cm.

the recognition of drawing as the most immediate and personal expression of the artist's hand. The pure pen drawing took its place by the side of other highly esteemed art forms. The English Art Nouveau artist Aubrey Beardsley at the end of the 19th century applied the direct black–white contrast to planes, while in the 20th century the French masters Henri Matisse and Picasso reduced the object to a mere line that makes no claim to corporeal illusion. A large number of illustrators, as well as the artists who draw the comic strips, prefer the clear pen stroke. In the Russian artist Wassily Kandinsky's nonrepresentational compositions, finally, the independence of the line as an autonomous formal value became a new theme in drawing. In the hair-thin automatist seismograms (so-called because of their resemblance to the records of earthquakes) of the 20th-century German artist Wols (Alfred Otto Wolfgang Schulze), which are sensitive to the slightest stirring of the hand, this theme leads to a new dimension transcending all traditional concepts of a representational art of drawing.



Pure line pen and ink drawing of the 20th century.
"Reclining Nude," by Pablo Picasso (1881–1973). In the Fogg Art Museum, Harvard University. 26 × 35 cm.

Although the brush is best suited to the flat application of pigments—in other words, to painting—its use in a clearly delineatory function, with the line dominating and (a crucial property of brush drawing) in monochrome fashion, can be traced back to prehistoric times.

All of the above-mentioned drawing inks have been used as dyes in brush drawings, often with one and the same pigment employed in combined pen-and-brush work. Still greater differentiation in tone is often obtained through concentrated or thinned mediums and with the addition of supplementary ones. To the latter belong chiefly distemper, a paint in which the pigments are mixed with an emulsion of egg or size or both, and watercolours, which can be used along with bistre and drawing ink. Even oils can sometimes be used for individual effects in drawing, as in the works of Jacob Jordaens.

Technique of sinopia

Sinopia, the preliminary sketch for a monumental wall painting, was done with the brush and has all the characteristics of a preparatory, form-probing drawing. The sketch was carried out directly on the appropriate spot and covered over with a thin layer of plaster, on which the pictorial representation was then painted.

The brush drawing differs from the pen drawing by its greater variation in stroke width, and by the stroke itself, which sets in more smoothly and is altogether less severely bordered. Early brush drawings nonetheless show a striking connection with the technique of the pen drawing. The early examples of the 15th century completely follow the flow of contemporaneous pen drawings. Leonardo's or Dürer's pen drawings, with their short, waxing and waning stroke layers, refine the system of pen drawing; many 16th-century artists used a comparable technique. The brush drawing for chiaroscuro sheets on tinted paper was popular because Chinese white, the main vehicle of delineation in this method, is more easily applied with the brush than the pen and because the intended pictorial effect is more easily attained, thanks to the possibility of changing abruptly to a plane representation.

Such representations are particularly distinctive as done by Vittore Carpaccio and Palma il Giovane in Venice and in a Mannerist spotting technique used by Parmigianino. In the 16th century, the brush nevertheless played a greater role as a supporting than as an independently form-giving instrument. Pure brush drawings were rare even in the 17th century, although the brush played a major role in landscapes, in which, by tinting of varying intensity, it ideally fulfilled the need to provide for all desired degrees of spatial depth and strength of lighting. Some Dutch artists, such as Adriaen Brouwer, Adriaen van Ostade, and Jan Steen, transcended the limits of drawing in the narrower meaning of the term by doing brushwork limited to a few tones within a monochrome scale, giving the impression of a pictorial watercolour.

Although the coloristically inclined 18th century was little interested in the restriction to a few shadings within one colour value, Jean-Honoré Fragonard raised this technique to perfection, with all its possibilities of sharply accented contours, soft delineation, delicate tones, and deep shadows. The brush drawings of the Spanish painter Francisco Goya must also be counted among the great achievements of this technique. In his strong plastic effects, the English painter George Romney made the most of the contrast between the white foundation and the broad brushstrokes tinted in varying intensities. Other English artists, among them Alexander Cozens, John Constable, and J.M.W. Turner, took advantage of the delicately graded pictorial possibilities for their landscape studies.

In the 19th century, the French artists Théodore Géricault, Eugène Delacroix, and Constantin Guys still followed the character of the brush drawing, even though it was already being replaced by the variegated watercolour and gouache painting, a method of painting with opaque colours that have been ground in water and mingled with a preparation of gum. In modern drawing, the brush has regained some importance as an effective medium for contrasting planes and as carrier of the theme; in this, the dry brush has proven itself a useful tool for the creation of a granular surface structure.

"Three Men Digging," by Francisco de Goya (1746–1828), brush drawing in sepia. In the Metropolitan Museum of Art, New York. 21 × 14 cm.

Pen and ink, chalk, silverpoint, and wash drawings

"Head of Girl" (study for "The Virgin of the Rocks," 1483), silverpoint on light brown paper by Leonardo da Vinci. In the Biblioteca Reale, Turin, Italy. 18.2 × 15.9 cm.

"An Island in the Lagoon," pen, brown ink, and carbon ink wash over ruled pencil lines by Canaletto (1697–1768). In the Ashmolean Museum, Oxford, England. 18.3 × 27.8 cm.

Study probably for "L'Indifférent," black, red, and white chalk on yellowish-gray paper by Jean-Antoine Watteau (1684–1721). In the Museum Boymans-van Beuningen, Rotterdam. 27.2 × 19 cm.

"Madonna with Many Animals," pen, ink, and watercolour by Albrecht Dürer, c. 1503. In the Albertina, Vienna. 32.1 × 24.3 cm.

Plate 1: By courtesy of (top left) Biblioteca Reale, Turin, Italy, (top right) the Ashmolean Museum, Oxford, England, (bottom left) the Albertina, Vienna, (bottom right) the Museum Boymans-van Beuningen, Rotterdam

"Le Château Noir," pencil and watercolour by Paul Cézanne, *c.* 1895–1900. In the Museum Boymans-van Beuningen, Rotterdam. 36 × 52.6 cm.

Crayon, pencil, sepia, and pastel drawings

"The Dancers," pastel on paper by Edgar Degas, 1899. In the Toledo Museum of Art, Ohio. 62 × 64.5 cm.

"Trees and a Stretch of Water on the Stour," pencil and sepia wash by John Constable (1776–1837). In the Victoria and Albert Museum, London. 16.2 × 20.3 cm.

"Two Women III," crayon on paper by Willem de Kooning, 1952. In the Allen Memorial Art Museum, Oberlin College, Ohio. 37.5 × 47 cm.

The combination of various techniques plays a greater role in drawing than in all other art forms. Yet it is necessary, in the numerous drawings in which two or more mediums are involved, to distinguish between those in which the mediums were changed in the course of artistic genesis and those in which an artistic effect based on a combination of mediums was intended from the beginning.

In the first case, one is confronted with a preliminary sketch, as it were, of the eventual drawing: the basic structure with some variations is tried out in charcoal, chalk, metalpoint, pencil, or some other (preferably dry and easily corrected) material and then carried out in a stronger and more durable medium. Most pen drawings are thus superimposed on a preliminary sketch. The different materials actually represent two separate stages of the same artistic process.

More relevant artistically is the planned combination of different techniques that are meant to complement each other. The most significant combination from the stylistic point of view is that of pen and brush, with the pen delineating the contours that denote the object and the brush providing spatial and plastic as well as pictorial—that is, colour—values. The simplest combined form is manuscript illumination, where the delineated close contours are filled in with colour. The drawing may actually be improved if this is done by a hand other than the draftsman's or at a later time.

Pen-and-brush combination

More important is brushwork that supplements linear drawing, in which entire segments may be given over to one technique or the other; for example, the considerable use of white (which is hard to apply with the pen) in drawings on tinted paper. In similar complementary fashion the brush may be used for plastic modelling as a way of highlighting, that is indicating the spots that receive the greatest illumination. The technique of combined pen-and-brush drawing was favoured by the draftsmen of Germany and the Netherlands, especially in the circle around Dürer and the south German Danube School. Shadows, too, can be inserted in a drawing with dark paint. The illusion of depth can also be achieved with white and dark colours in a pure chalk technique.

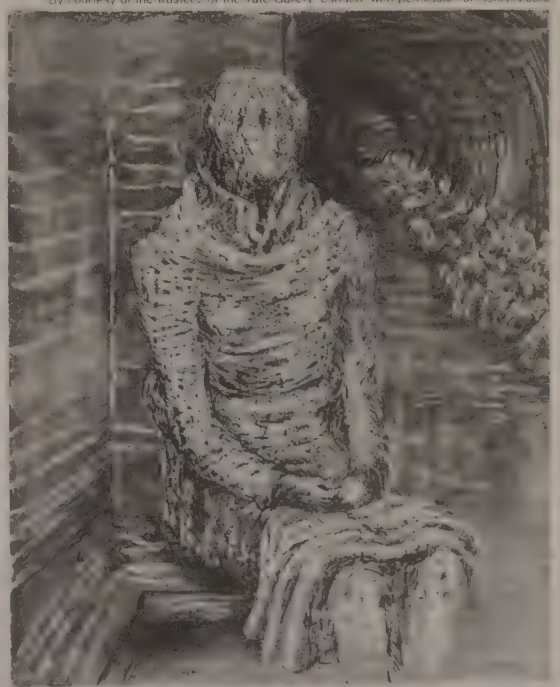
In contrast to these methods, which still belong to a linear system of drawing, is the flat differentiation of individual segments of a work in (usually) the same medium: wash. Various bodies and objects are evenly tinted with the brush within or along the drawn contours. Planes are thus contrasted with lines, enhancing the illusionary effect of plasticity, space, and light and shadow. This modelling wash has been used again and again since the 16th century, sometimes in combination with charcoal, chalk, or pencil drawings. A further refinement, used particularly in landscape drawings, is wash in varying intensities; additional shadings in the sense of atmospheric phenomena, such as striking light and haze merging into fog and cloud, can be rendered through thinning of the colour or repeated covering over a particular spot. A chromatic element entered drawing with the introduction of diluted indigo, known in the Netherlands from the East India trade; it is not tied to objects but used in spatial and illusionist fashion, by Paul Brill and Hans Bol in the 16th and 17th centuries, for example. The mutual supplementation and correlation of pen and brush in the wash technique was developed most broadly and consistently in the 17th century, in which the scaffold, so to speak, of the pen drawing became lighter and more open, and brushwork integrated corporeal and spatial zones. The transition from one technique to the other—from wash pen drawings to brush drawings with pen accents—took place without a break. Claude Lorrain and Nicolas Poussin in 16th- and 17th-century France are major representatives of the latter technique, and Rembrandt once again utilized all its possibilities to the full.

Whereas this method served—within the general stylistic intentions of the 17th century—primarily to elucidate spatial and corporeal proportions, the artists of the 18th century employed it to probe this situation visually with the aid of light. The unmarked area, the spot left empty, has as much representational meaning as the pen contours, the lighter or darker brush accent, and the tinted area.

The art of omission plays a still greater role, if possible, in the later 19th century and in the 20th. Paul Cézanne's late sheets, with their sparse use of the pencil and the carefully measured out colour nuances, may be considered the epitome of this technique. As the colouring becomes increasingly varied through the use of watercolours to supplement a pen or metalpoint drawing, one leaves the concept of drawing in the strict sense of the term. According to the quality and quantity of the mediums employed, one then speaks of "drawings with watercolour," "watercolourized drawings," and "watercolours on preliminary drawings." The predominant stroke character, rather than the fact that paper is the carrier, is the chief feature when deciding whether or not the work may legitimately be called a drawing.

Combination of dry and fluid drawing mediums

The combination of dry and fluid drawing mediums provides a genuine surface contrast that may be exploited for sensuous differentiation. Here again a distinction must be made between various ways of applying the identical medium—for example, charcoal and charcoal dust in a water solution or, more frequently, sanguine and sanguine rubbed in with a wet brush—and the stronger contrast brought about by the use of altogether different mediums. Chalk drawings are frequently washed with bistre or watercolour, after the principle of the washed pen drawing. Stronger contrasts, however, can be obtained if the differing techniques are employed graphically, as the Flemish draftsmen of the 17th century liked to do. The Chinese ink wash of chalk drawings also contributes to the illusion of spatial depth. Along with such Dutch painters as Jan van Goyen and members of the family van de Velde, Claude Lorrain achieved great mastery in this technique. The differentiated treatment of the foreground with pen and brush and the background with chalk renders spatial depth plausible and plastic. In modern art, the use of different mediums—whether for plastic differentiation, such as Henry Moore carried out with unequalled mastery in his "Shelter Drawings," or only for the purpose of contrasting varied surface stimuli of nonrepresentational compositions as well as the enrichment with colours and even with collage elements (the addition of paper, metal, or other actual objects) broadens the concept of the drawing so that it becomes an autonomous picture the mixed technique of which transcends the borderline between drawing and painting.



Use of different mediums to emphasize sculptural effects, "Women Seated in the Underground," crayon and wash drawing by Henry Moore, 1941. In the Tate Gallery, London. 48.3 × 38.1 cm.

Mechanical devices. Mechanical aids are far less important for art drawing than for any other art form. Many draftsmen reject them altogether as unartistic and inimical to the creative aspect of drawing.

Apart from the crucial importance that mechanical aids have had and continue to have for all kinds of construction diagrams, plans, and other applied drawings, some mechanical aids have been used in varying but significant measure for artistic drawings. The ruler, triangle, and compass as basic geometric instruments have played a major role, especially in periods in which artists created in a consciously constructionist and perspectivist manner. Marks for perspective constructions may be seen in many drawings of early and High Renaissance vintage.

For perspectively correct rendition, the graticulate frame, marked off in squares to facilitate proportionate enlargement or reduction, allowed the object to be drawn to be viewed in line with a screen on the drawing surface. Fixed points can be marked with relative ease on the resultant system of coordinates. For portrait drawings, the glass board used into the 19th century had contours and important interior reference points marked on it with grease crayons or soap sticks, so that they could be transferred onto paper by tracing or direct copying. Both processes are frequently used for preliminary sketches for engravings to be duplicated, as is the screened transmission of a preliminary sketch onto the engraving plate or, magnifying, the painting surface. In such cases the screen lies over the preparatory drawing.

Mirrors and mirror arrangements with reducing convex mirrors or concave lenses were likewise used (especially in the 17th and 18th centuries) as drawing aids in the preparation of reproductions. Even when it was a matter of the most exact rendition of topographical views, such apparatus, as well as the camera obscura (a darkened enclosure having an aperture usually provided with a lens through which light from external objects enters to form an image on the opposite surface), were frequently employed. In a darkened room the desired section is reflected through a lens onto a slanting mirror and from that inverse image is reflected again onto the horizontally positioned drawing surface. Lateral correction can be obtained by means of a second mirror.

Unless the proportions do not allow it, true-to-scale reducing or enlarging can also be carried out with the aid of the tracing instrument called the pantograph. When copying, the crayon or pencil inserted in the unequally long feet of the device reproduces the desired contours on the selected scale.

Most of these aids were thus used in normal studio practice and for the preparation of certain applied drawings. Equally practical, but useful only for closely circumscribed tasks, were elliptic compasses, curved rulers, and stencils, particularly for ornamental and decorative purposes. Only a few present-day artists use stencils or simple blocks with a given shape in larger scale composition, in order to obtain the effect of repetition, often in an arbitrary use, in "alienating" technique and colour.

Mechanically produced drawings

Mechanically produced drawings such as typewriter sketches, computer drawings, and oscillograms, all of which can bring forth unusual and attractive results, nevertheless do not belong to the topic because they lack the immediate creativity of the art drawing.

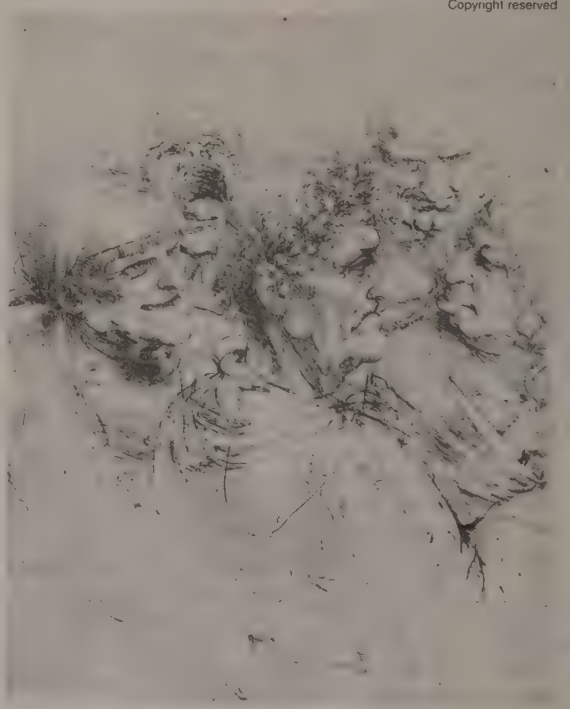
APPLIED DRAWINGS

Applied and technical drawings differ in principle from art drawings in that they record unequivocally an objective set of facts and on the whole disregard aesthetic considerations. The contrast to the art drawing is sharpest in the case of technical project drawings, the purpose of which is to convey not so much visual plausibility as to give exact information that makes possible the realization of an idea. Such plans for buildings, machines, and technical systems are not instantly readable because of the orthogonal (independent) projection, the division into separate planes of projection, and the use of symbols. Prepared as a rule with such technical aids as ruler and compass, they represent a specialized language of their own, which must be learned. For topographic (detailed delineation of the features of a place) and cartographic (map-making) drawings, too, a special terminology has developed that above all systematizes spatial representations, making them intelligible to the expert with the aid of emblems and symbols.

Equally far removed from any claim to artistic standing are most illustrations serving scientific purposes, the aim of which is to record as objectively as possible the characteristic and typical features of a given phenomenon. The systematic drawings, used especially in the natural sciences to explain a system or a function, resemble plans; descriptive and naturalistic illustrations, on the other hand, approach the illusionistic plausibility of visual experience and can attain an essentially artistic character. A good many artists have drawn scientific illustrations, and their works—the botanical and zoological drawings of the Swiss Merian family in the 17th and 18th centuries, for example—are today more esteemed for their artistic than for their documentary value.

Of a similarly ambivalent nature is the illustrative drawing that perhaps does not go beyond a simple pictorial rendition of a literary description but because of its specific formal execution may still satisfy the highest artistic demands. Great artists have again and again illustrated Bibles, prayerbooks, novels, and literature of all kinds. Some of the famous examples are Botticelli's illustrations for Dante's *Divine Comedy* and Dürer's marginal illustrations for the emperor Maximilian's prayer book. Some artists have distinguished themselves more as illustrators than as autonomous draftsmen, as for example the 18th-century German engraver Daniel Chodowiecki, the 19th-century caricaturist Honoré Daumier, the 19th-century satiric artist Wilhelm Busch, and the 20th-century Austrian illustrator Alfred Kubin.

Clearly connected with illustrative drawing is caricature, which, by formally overemphasizing the characteristic traits of a person or situation, creates a suggestive picture that—precisely because of its distortion—engraves itself on the viewer's mind. This special kind of drawing was done by such great artists as Leonardo, Dürer, and the 17th-century artist Gian Lorenzo Bernini and by draftsmen who, often for purposes of social criticism, have devoted themselves wholly to caricaturing, such as the 18th-century Italian Pier Leone Ghezzi, the 19th-century Frenchman Grandville (professional name of Jean-Ignace-Isidore Gérard), and Daumier.



"Five Grotesque Heads," pen and ink drawing by Leonardo (1452–1519). In the Royal Library, Windsor Castle. 26 × 20.5 cm.

Modern cartoons

From such overdrawn types developed continuous picture stories that could dispense to a considerable extent with the explanatory text. Modern cartoons are based on these picture stories. Through the formally identical treatment of peculiar types, these drawings acquire an element of consecutiveness that, by telling a continuing story, adds a temporal dimension to two-dimensional drawing. This element is strongest in trick drawings that fix on paper, in brief segments of movement, invented creatures and phenomena that lack all logical plausibility; a rapid sequence of images (leafing through the pages, seeing it projected on the screen) turns the whole into apparent motion, the fundamental process of animation. The artistic achievement, if any, lies in the original invention; its actual realization is predetermined and sometimes carried out by a large and specialized staff of collaborators, often with the aid of stencils and traced designs. Moreover, since the final result is partially determined by the mechanical multiplication, an essential criterion of drawing—the unity of work and result—does not apply.

SUBJECT MATTER OF DRAWING

Anything in the visible or imagined universe may be the theme of a drawing. In practice, however, by far the greatest number of art drawings in the Western world deal with the human figure. This situation springs from the close bond between drawing and painting: in sketches, studies, and compositions, drawing prepared the way for painting by providing preliminary clarification and some formal predetermination of the artist's concept of a given work. Many drawings now highly regarded as independent works were originally "bound," or "latent," in that they served the ends of painting or sculpture. Yet, so rounded, self-contained, and aesthetically satisfying are these drawings that their erstwhile role as handmaidens to the other pictorial arts can be reconstructed only from knowledge of the completed work, not from the drawing itself. This situation is especially true of a pictorial theme that acquired, at a relatively early stage, an autonomous rank in drawing itself: the portrait.

Portraits. Drawn 15th-century portraits—by Pisanello or Jan van Eyck, for example—may be considered completed pictorial works in their concentration, execution, and distribution of space. The clear, delicately delineated representation follows every detail of the surface, striving for realism. The profile, rich in detail, is preferred; resembling relief, it is akin to the medallion. Next in prominence to the pure profile, the three-quarter profile, with its more spatial effect, came to the fore, to remain for centuries the classic portrait stance.

The close relationship to painting applies to practically all portrait drawings of the 15th century. Even so forceful a work as Dürer's drawing of the emperor Maximilian originated as a portrait study for a painting. At the same time, however, some of Dürer's portrait drawings clearly embody the final stage of an artistic enterprise, an ambivalence that can also be observed in other 16th-century portraitists. The works of Jean and François Clouet in France and of the younger Hans Holbein in Switzerland and even more markedly in England in the same century bestowed an autonomy on portrait drawing, especially when a drawing was completed in chalk of various colours. The choice of the softer medium, the contouring, which for all its exactitude is less severely self-contained, and the more delicate interior drawing with plane elements gives these drawings a livelier, more personal character and accentuates once more their proximity to painting.

Chalk and pastel portraits

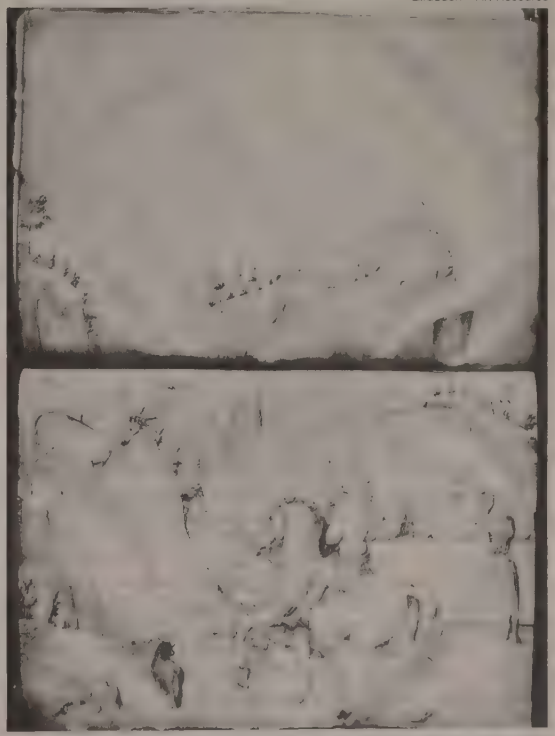
In polychromatic chalk technique and pastel, portrait drawing maintained its independence into the 19th century. In the 18th century, Quentin de La Tour, François Boucher, and Jean-Baptiste Chardin—all of these artists from France—were among its chief practitioners, and even Ingres, living in the 19th century, still used its technique. In pastel painting, the portrait outweighed all other subjects.

In the choice of pose, type, and execution, portrait painting, like other art forms, is influenced by the general stylistic features of an epoch. Thus, the extreme pictorial attitude of the late Baroque and Rococo was followed by a severer conception during Neoclassicism, which preferred monochrome techniques and cultivated as well the special form of the silhouette, a profile contour drawing with the area filled in in black. Unmistakably indebted to their 15th-century predecessors, the creators of portrait drawings of the early 19th century aimed once more at the exact rendition of detail and plastic effects gained through the most carefully chosen graphic mediums: the thin, hard pencil was their favourite instrument, and the silverpoint, too, was rediscovered by the Romantics.

More interested in the psychological aspects of portraiture, late 19th- and 20th-century draftsmen prefer the softer crayons that readily follow every artistic impulse.

"Portrait of Marguerite de Valois," chalk drawing by François Clouet, *c.* 1559. In the Musée Condé, Chantilly, France. 30.1 × 21.1 cm.
Giraudon—Art Resource

Giraudon—Art Resource



"St. Hubert," two pages from a sketchbook by Jacopo Bellini (*c.* 1400–*c.* 1470), pen and ink over chalk or lead point. In the British Museum. 67.2 × 41.5 cm.

The seizing of characteristic elements and an adequate plane rendition weigh more heavily with them than realistic detail. Mood elements, intellectual tension, and personal engagement are typical features of the modern portrait and thus also of modern portrait drawing, an art that continues to document the artist's personal craftsmanship beyond the characteristics of various techniques.

Landscapes. As early as the 15th century, landscape drawings, too, attained enough autonomy so that it is hard to distinguish between the finished study for the background of a particular painting and an independent, self-contained sketched landscape. Already in Jacopo Bellini's 15th-century sketchbooks (preserved in albums in the British Museum and the Louvre), there is an intimate connection between nature study and pictorial structure; in Titian's studio in the 16th century, landscape sketches must have been displayed as suggestions for pictorial backgrounds.

But it was Dürer who developed landscape as a recollected image and autonomous work of art, in short, as a theme of its own without reference to other works. His watercolours above all but also the drawings of his two Italian journeys, of the surroundings of Nürnberg, and of the journey to the Netherlands, represent the earliest pure landscape drawings. Centuries had to pass before such drawings occurred again in this absolute formulation.

Landscape elements were also very significant in 16th-century German and Dutch drawings and illustrations. The figurative representation, still extant in most cases, is formally quite integrated into the romantic forest-and-meadow landscape, particularly in the works of the Danube School—Albrecht Altdorfer and Wolf Huber, for example. More frequently than in other schools, one finds here carefully executed nature views. In the Netherlands, Pieter Bruegel drew topographical views as well as free landscape compositions, in both cases as autonomous works.

"The Sacrifice of Isaac," by Albrecht Altdorfer (1480?–1538), pen and ink, heightened with white, on gray-green paper. In the Albertina, Vienna. 20.8 × 17.5 cm.

17th-century landscape drawing

In the 17th century, the nature study and the landscape drawing that grew out of it reached a new high. The landscape drawings of the Accademia degli Incamminati (those of Domenichino, for example) combined classical and mythological themes with heroic landscapes. The Frenchman Claude Lorrain, living in Rome, frequently worked under the open sky, creating landscape drawings with a hitherto unattained atmospheric quality. This type of cultivated and idealized landscape, depicted also by Poussin and other Northerners residing in Rome (they were called Dutch Romanists in view of the fact that so many artists from the Netherlands lived in Rome, their drawings of Italy achieving an almost ethereal quality), is in contrast with the unheroic, close-to-nature concept of landscape held primarily by the Netherlanders when depicting the landscape of their native country. All landscape painters—their landscape paintings a specialty that was strongly represented in the artistically specialized Low Countries—also created independent landscape drawings (Jan van Goyen and Jacob van Ruisdael and his uncle and cousin, for example), with Rembrandt again occupying a special position: capturing the characteristics of a region often with only a few strokes, he enhanced them in such manner that they acquire monumental expressive power even in the smallest format. In 18th-century Italy, the topographically faithful landscape drawing gained in importance with the advent of the *Vedutisti*, the purveyors of "views," forming a group by themselves (among them, Giambattista Piranesi and Canaletto [Giovanni Antonio Canal]) and often working with such optical aids as the graticulate frame and camera obscura. Landscape drawings of greater artistic freedom, as well as imaginary landscapes, were done most successfully by some French artists, among them Hubert Robert; pictorially and atmospherically, these themes reached a second flowering in the brush-drawn landscapes of such English artists as Turner and Alexander Cozens, whose influence extends well into the 20th century.

Given their strong interest in delineation, the 18th-century draftsmen of Neoclassicism and, even more, of Romanticism observed nature with topographical accuracy. As a new "discovery," the romantically and heroically exaggerated Alpine world now took its place in the artist's mind alongside the arcadian view of the Italian landscape.

Landscape drawings and even more, watercolours, formed an inexhaustible theme in the 19th century. The French artist Jean-Baptiste-Camille Corot and, toward the end of the century, Cézanne and van Gogh, were among the chief creators of landscape drawings. While landscapes form part of the work of many 20th-century draftsmen, the genre as such takes second place to general problems of form, in which the subject is merely treated as starting point.

Figure compositions and still lifes. Compared to the main themes of autonomous drawing—portraiture and landscape—all others are of lesser importance. Figure compositions depend greatly on the painting of their time and are often directly connected with it. There were, to be sure, artists who dealt in their drawings with the themes of monumental painting, such as the 17th-century engraver and etcher Raymond de La Fage; in general, however, the artistic goal of figure composition is the picture, with the drawing representing but a useful aid and a way station. Genre scenes, especially popular in the 17th-century Low Countries (as done by Adriaen Brouwer, Adriaen van Ostade, and Jan Steen, for example) and in 18th-century France and England, did attain some independent standing. In the 19th century, too, there were drawings that told stories of everyday life; often illustrative in character, they may be called "small pictures," not only on account of the frequently multicoloured format but also in their artistic execution.

Still lifes can also lay claim to being autonomous drawings, especially the representations of flowers, such as those of the Dutch artist Jan van Huysum, which have been popular ever since the 17th century. Here, again, it is true that a well-designed arrangement transforms an immediate nature study into a pictorial composition. In some of these compositions the similarity to painting is very strong; the pastels of the 19th- and 20th-century artist Odilon Redon, for instance, or the work of the 20th-century German Expressionist Emil Nolde, with its chromatic intensity, transcend altogether the dividing line between drawing and painting. In still lifes, as in landscapes, autonomous principles of form are more important to modern artists than the factual statement.

Fanciful and nonrepresentational drawings. Drawings with imaginary and fanciful themes are more independent of external reality. Dream apparitions, metamorphoses, and the entwining of separate levels and regions of real-

Contrasting approaches to the representation of landscape.

ity have been traditional themes. The late 15th-century phantasmagoric works of Hieronymus Bosch are an early example. There are allegorical peasant scenes by the 16th-century Flemish artist Pieter Bruegel and the carnival etchings of the 17th-century French artist Jacques Callot. Others whose works illustrate what can be done with drawing outside landscape and portraiture are: the 18th-century Italian engraver Giambattista Piranesi, the 18th-century Anglo-Swiss artist Henry Fuseli, the 19th-century English illustrator Walter Crane, the 19th-century French Symbolist artist Gustavè Moreau, and the 20th-century Surrealists.

Nonrepresentational art

Nonrepresentational art, with its reduction of the basic elements of drawing—point, line, plane—to pure form, offered new challenges. Through renunciation of associative corporeal and spatial relationships, the unfolding of the dimensions of drawing and the structure of the various mediums acquire new significance. The graphic qualities of the line in the plane as well as the unmarked area had already been emphasized in earlier times—for example, in the *grotteschi* of Raphael in the 16th century (the fanciful or fantastic representations of human and animal forms often combined with each other and interwoven with representations of foliage, flowers, fruit, or the like) and in calligraphic exercises such as moresques (strongly stylized linear ornament, based on leaves and blossoms)—but mostly as printing or engraving models for the most disparate decorative tasks (interior decoration, furniture, utensils, jewelry, weapons, and the like).

Artistic architectural drawings. There is one field in which drawing fulfills a distinct function: artistic architectural drawings are a final product as drawings, differing from the impersonal, exact plans and designs by the same "handwriting" character that typifies art drawings. In many cases, no execution of these plans was envisaged; since the early Renaissance, such ideal plans have been drawn to symbolize, in execution and accessories, an abstract content. Despite the often considerable exactitude with which the plans are drawn, the personal statement

"Design for a Wall Panel," by Giambattista Piranesi (1720–78), pen with brown ink, brown wash, over black chalk. In the Pierpont Morgan Library, New York. 28.8 × 28.2 cm.

predominates in the flow of the line. This personal note clearly identifies the drawings of such artists and architects as Albrecht Altdorfer, Leonardo, Michelangelo, Bernini, Francesco Borromini, and Piranesi. Also distinct from the ground-plan type of architectural drawing are the art drawings of autonomous character created by such 20th-century architects as Erich Mendelsohn and Le Corbusier.

History of drawing

WESTERN

As an artistic endeavour, drawing is almost as old as mankind. In an instrumental, subordinate role, it developed along with the other arts in antiquity and the Middle Ages. Whether preliminary sketches for mosaics and murals or architectural drawings and designs for statues and reliefs within the variegated artistic production of the Gothic medieval building and artistic workshop, drawing as a nonautonomous auxiliary skill was subordinate to the other arts. Only in a very limited sense can one speak of centres of drawing in the early and High Middle Ages; that is, the scriptoria of the monasteries of Corbie and Reims in France, as well as those of Canterbury and Winchester in England, and also a few places in southern Germany, where various strongly delineatory (graphically illustrated) styles of book illumination were cultivated.

14th, 15th, and 16th centuries. In the West, the history of drawing as an independent artistic document began toward the end of the 14th century. If its development was independent, however, it was not insular. Just as the greatest draftsmen have been for the most part also distinguished painters, illustrators, sculptors, or architects, so the centres and the high points of drawing have generally coincided with the leading localities and the major epochs of the other arts. Moreover, the same stylistic phenomena have been expressed in drawing as in other art forms. Indeed, drawing shares with other art forms the characteristics of individual style, period style, and regional features. Drawing differs, however, in that it interprets and renders these characteristics in terms of its own unique mediums.

Drawing as an independent art form

Drawing became an independent art form in northern Italy, at first quite within the framework of ordinary studio activity. But with nature studies, copies of antiques, and drafts in the various sketchbooks (those of Giovannino de'Grassi, Antonio Pisanello, and Jacopo Bellini, for example), the tradition of the Bauhütten studio workshop changed to individual work: the place of "exempla," models, reproduced in formalized fashion was now being taken by subjectively probing and partially creative drawings. In the early 15th century the international Soft Style of the period still largely predominated over the draftsman's individual "handwriting." At mid-century, however, the differentiation of drawing style according to region and the artist's personality set in. Essential criteria, destined to remain characteristic for generations, begin to strike the eye.

In drawing produced north of the Alps, the characteristic features lie in the tendency to pictorial compactness and precise execution of detail. Many painters produced individual drawings, but the most notable draftsmen are the otherwise unidentified 15th-century German Master of the Housebook and his contemporary Martin Schongauer. Both of these artists were also major copperplate engravers, so that it is not always easy to determine whether the work is a preliminary sketch or an independent drawing.

In Italian Renaissance drawings, of which there are a great many, the diverging stylistic features of the various artistic regions were particularly evident. What they had in common was the overwhelming importance of the sketch and the study, in contrast to the far rarer finished drawings. The formal and thematic connection with painting is very close even when it was not a question of preliminary drawings. The draftsmen of Venice and northern Italy preferred an open form with loose and interrupted delineation in order to achieve even in drawing the pictorial effect that corresponded to their painters' imagination.

In central Italy, on the other hand, and especially in Florence, it was the clear contour that predominated, the closed and firmly circumscribed form, the static and plastic character. Corresponding to the functional purpose of drawing, the individual artists' studios (which, as was the case with the Medicis' Academy of St. Mark, also had to engage in general educational and humanistic investigations) formed the most significant centres of art drawing. In these large studios, drawing served not only for the probing realization of creative ideas, it was not only study and mediator between the conception and the master's finished work; it functioned also as teaching aid for the

assistants who worked with the master and as a vehicle for the formation and preservation of an individual workshop tradition. Although Leonardo's scientific interests were expressed in a large number of drawings, his ideal concept of the human figure is much more frequently preserved in the drawings of his collaborators and successors than in his own. Raphael and Michelangelo were also outstanding draftsmen. Each of them used drawing in order to allow his thoughts about individual works to mature; each had a highly personal drawing style, the one with a soft and rounded stroke, the other with a sculptor's intermittent and powerful stroke. Probably a great deal of drawing was done in Raphael's studio, especially if only for the preparation of the engravings after Raphael's compositions. From Michelangelo's hand came the first so-called connoisseur drawings that are esteemed as a personal document. They are the precursors of the collector's drawings that began in the later 16th century (autonomous works, destined for collections).

Northern European drawing

North of the Alps the autonomy of drawing was championed in the first instance by Dürer, an indefatigable draftsman who mastered all techniques and exercised an enduring and widespread influence. The delineatory constituent clearly predominates even in his paintings. This corresponds to the general stylistic character of 16th-century German art, within which Matthias Grünewald, with his freer, broader, and therefore more pictorial style of drawing, and the painters of the Danube school, with their ornamentalizing and agitated stroke, represent significant exceptions. In their metamorphosing of the perceived reality into drawings, the landscapes of Altdorfer and Wolf Huber in particular are astonishing documents of a feeling for nature that might almost be called Romantic.

Soberer, incredibly compact in their pictorial concept and yet akin to the Renaissance in their objective viewing, were the portrait drawings of Hans Holbein, the Younger, whose sojourns in 16th-century England proved stimulating to other artists as well. Similar, if less personal than Holbein because of the stricter linearity of their work, were the drawings of the French portraitists Jean and François Clouet. In the Low Countries, where they were combined with the idealized image of Italy (as in the drawings of Lucas van Leyden), Dürer's methods gained lasting popularity in the landscape drawings and studies "after life" by Pieter Bruegel the Elder.

Drawing acquired a pivotal significance in the period of Mannerism (*c.* 1525–1600), both as a document of artistic invention and as a means of its realization. Jacopo Pontormo in Florence, Parmigianino in northern Italy, and Tintoretto in Venice used point and pen as essential and spontaneous vehicles of expression. Their drawings were clearly related to their painting, both in content and in the graphic method of sensitive contouring and daringly drawn foreshortening.

17th, 18th, and 19th centuries. In the early 17th century, Jacques Callot rose to prominence in French art: gifted as a draftsman above all, he recorded with the pen his clever inventions and great picture stories, primarily in bold abbreviations.

The importance of drawing for an artist's growth and the widening of his horizon is attested also by the work of Peter Paul Rubens, whose studies and sketches make up an integral part of his creative achievement. In order to disseminate his pictorial themes and concept of form, he maintained his own school for draftsmen and engravers. Among the circle of Flemings around him, Jacob Jordaens and Sir Anthony Van Dyck are notable as draftsmen with a style of their own.

Hercules Seghers was among the most fascinating artists of the 17th century, a creator of drawn and etched landscapes that he continued to rework while experimenting with printing processes. From the point of view of technique and form, he was important for the greatest artist of Holland, Rembrandt. Seghers combined great inventiveness, especially in his interpretations of Old Testament motifs, and broad mastery of all the techniques of drawing. In his studio, too, drawing was emphasized as a teaching aid and a means of formal experimentation.

Most Dutch painters of the 17th century, such as the van de Velde family, Brouwer, van Ostade, Pieter Saenredam, and Paulus Potter, were also industrious draftsmen who recorded their special thematic concerns in drawings that were largely completed. Beyond serving as preparation for paintings, these were regarded as autonomous works representing the final stage of the creative process.

17th-century Italian landscape drawing

In 17th-century Italy, drawing by way of artistic practice and experimentation became established in the academies, especially in Bologna. More significant, however, was the continuing development of landscape drawing, as initiated by the brothers Agostino and Annibale Carracci and articulated further by Domenichino and Salvator Rosa. The French artist Claude Lorrain so developed the landscape drawing of the Roman countryside that it became almost a genre of its own; in his works, which were often intended for sale, nature study and an idealized pictorial concept are uniquely merged. In detailed studies directly before the object, he achieved a timeless validity. Like Lorrain, Poussin also drew under the open sky. Using various techniques, he combined realistic experiences and humanistic concepts in idealizing compositions the figures and scenes of which are harmoniously integrated into a spacious landscape. This open-air painting and drawing was practiced also by some other artists who spent a considerable time in Rome—the Dutch artists Jan Asselijn, Claes Berchem, Karel Dujardin, and Adam Pijnacker, for example. For most southern European artists of the 17th century, however, drawing was a mere stage in the creation of a painting.

Antoine Watteau, too, did drawings to "keep his hand in" for his painting, although he did so with an independence that led him far beyond the immediate occasion. Most figures in the paintings from various periods of his career were based on earlier drawings. In the grand scale of his form and the attention paid to pictorial elements, he carried on in the manner of Rubens, combining it with the light esprit of the 18th century. The leading position of French art in the first half of that century was confirmed by the achievements of Boucher, Fragonard, Hubert Robert, and Gabriel de Saint-Aubin, whose drawings include figure studies, genre-like works, and landscapes.

In contrast to the French draftsmen who brought about a flowering of the *à trois crayons* method on tinted paper, some artists created similar landscapes with pen and brush but with greater objective abbreviation. Mention must here be made of Venice, with the Giovanni Battista Tiepolo family, whose expansively conceived pen drawings, washed with a broad brush, call forth the kind of luminaristic effect that Francesco Guardi also used for landscape studies and imaginary scenes. These had been preceded by Canaletto's views of Venice, composed more severely as far as tectonic (constructional) detail is concerned but nonetheless the first examples of this form of the landscape capriccio, or fantasy. The architect Giambattista Piranesi made his name primarily as a draftsman who recorded views of Rome; above all, in his drawings of architecture and eerie vaults ("Carceri"), he left behind a body of work of great intellectual and formal forcefulness.

The Spanish painter Goya, at the very end of the 18th and in the beginning of the 19th century, was in advance of his time in the way in which he handled his themes. Forming an odd contrast to the court-painter's pictures, his brush-and-sanguine drawings are rather more closely tied to his cycles of etchings. He combined the luminaristic effects of Tiepolo's drawings with the dramatic impact of a Rembrandt chiaroscuro.

Also at the turn of the 19th century is an artist whose main work was that of a draftsman: the English caricaturist and social satirist Thomas Rowlandson, who produced colourful and distinctive watercolours. The late 18th and, even more, the early 19th century produced a drawing style that, in accordance with both the Neoclassical and the Romantic ideal, emphasized once more the linear element. In Ingres, idealistic Neoclassicism found an exemplary expression of strict linearity, and the pencil drawing became a downright classical form. The Nazarenes and Romantics in Rome and the Alpine region (Joseph Anton Koch, the brothers Friedrich and Ferdinand Olivier, and Julius Schnorr von Carolsfeld) as well as those in

north Germany (Philipp Otto Runge and Caspar David Friedrich) were more lyrical but equally rigorous in the use of the hardpoint; after a long time, they were the first northern artists to have made a significant contribution to the history of drawing. Among 19th-century artists, the emphasis on delineation was characteristic also of Moritz von Schwind in Germany and John Millais in England. (In the Neoclassical phase of the 20th century it was renewed, in a more open and "handwriting" fashion, by Thomas Eakins in the United States as well as by Picasso, Matisse, and Amedeo Modigliani in France.) The drawings of Delacroix, while preserving plastic qualities, show a broader stroke and are thus more pictorial. Daumier, active in all mediums primarily as a draftsman, utilized pictorial chiaroscuro effects in forcible statements of social criticism.

19th-century France

France continued to be a leading centre of the art of drawing, a form that was given a very personal note in each case in the works of Degas, Toulouse-Lautrec, van Gogh, and Cézanne. The line—the common point of departure for all of the above-mentioned artists—did not disappear until Seurat's plane shading, done in the Pointillist manner.

Modern. Except for a few stylistic currents such as Tachism (paintings consisting of irregular blobs of colour), drawing is represented in the work of practically all 20th-century artists; it is as international as modern art itself. As the other arts have become nonrepresentational, thus attaining autonomy and formal independence in relation to external reality, drawing is more than ever considered an autonomous work of art, independent of the other arts; and the sketch, study, and project—that is, the drawing as a stage in the genesis of works of sculpture, painting, and architecture—have greatly diminished in importance. Some schools and individual artists as well have concentrated on drawing and in very individualistic ways. The German Expressionists, for instance, developed especially emphatic forms of drawing with powerful delineation and forcible and hyperbolic formal description; notable examples are the works of Ernst Barlach, Käthe Kollwitz, Alfred Kubin, Ernest Ludwig Kirchner, Karl Schmidt-Rottluff, Max Beckmann, and George Grosz. In the artists' group *Der Blaue Reiter* (The Blue Rider), Wassily Kandinsky was foremost in laying the groundwork for a new evaluation of the nonrepresentational line. Paul Klee's lyrically sensitive drawings, carried out in a pen technique of unheard-of sublimity, represent a high point of modern drawing. In France, drawing plays a major role, especially in the work of the painters of the École de Paris (School of Paris), such as Pierre Soulages and Hans Hartung, who consider the line, the framework of lines, and the network of lines, as primary manifestations of form. Wols (Alfred Otto Wolfgang Schulze) and also the English artist Graham Sutherland may actually be called spiritual draftsmen who put their faith in the magic of the line. Finally, drawing occupies a considerable place in the work (including all its variants of style and form) of Picasso, once again a man who knew how to make use of its manifold technical possibilities. One is surely justified in calling him the greatest draftsman of the 20th century and one of the greatest in the history of drawing. (H.R.H.)

EASTERN

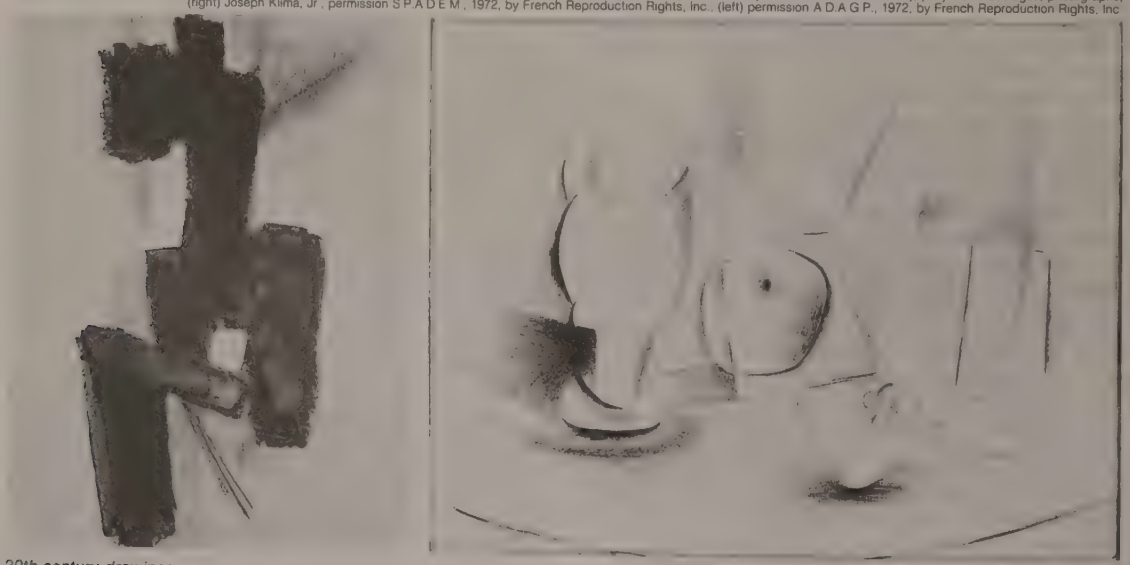
Drawings of China

Some form of monochromatic brush drawing with ink may have been practiced in China as early as the 2nd millennium BC; but the earliest pictorial work is in lacquer or on bronze vessels, contemporaneous with Alexander the Great (ruled 336–323 BC). It relies on contour and silhouette, with men and animals depicted in horizontal registers (levels, one above the other) reminiscent of Egyptian and Mediterranean work. The extent of any mutual influence between East and West cannot yet be determined. Under the Tung (Eastern) Han dynasty (AD 25–220) wall paintings, linear in character, were produced in fresco (wet plaster) and secco (dry). Only in the Wei (386–534/35) and T'ang (618–907) dynasties did the true character of Chinese drawing on silk or paper emerge. In the 7th century, the characteristic albums (*ts'e-yeh*) of drawings appear.

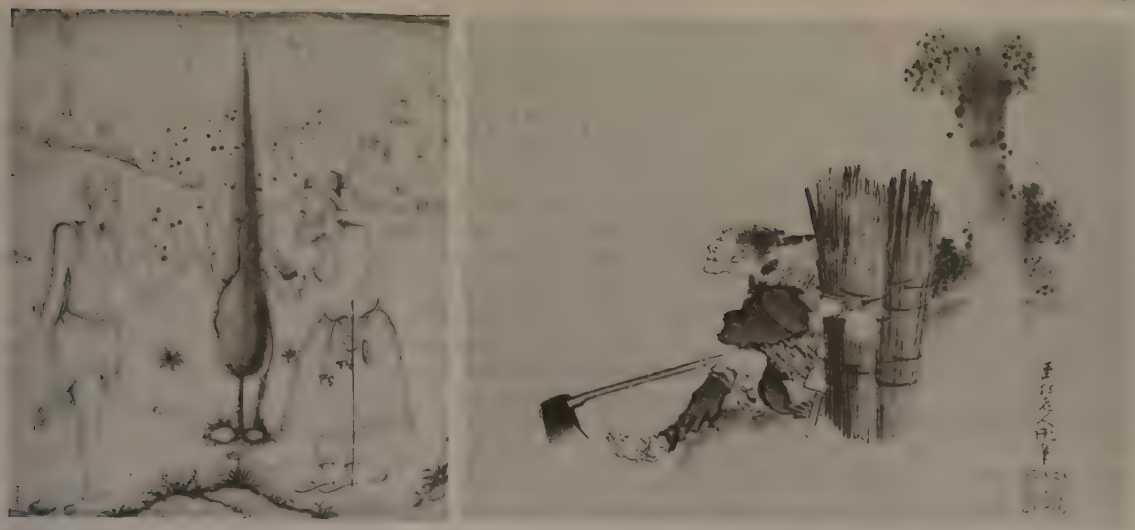
No distinction was made between drawing and painting because all Chinese pictorial art was fundamentally graphic. The artist worked with the fine point of the brush on paper or silk laid horizontally on a table. Work in pure outline was called *pai-miao*; ink applied in splashes, *p'o-mo*. Colour was used sparingly or not at all. The final work was not made direct from nature.

Hindu and Buddhist paintings at Ajantā in India and also in Ceylon reveal the essential quality in all Indian art: emphasis on a flowing, rhythmic contour to express movement and gesture. Drawings on palm leaf of the 11th century are similarly based on the use of line to depict mythological scenes.

The 14th century saw the manufacture of paper, introduced from China, permitting the production of the vertical book. Despite the Muslim prohibition of human representation, books illustrated with drawings, sometimes with flat decorative colour, were produced at the Persian and Mughal courts, but not for public display. The use



20th-century drawings.
(Left) Drawing by Pierre Soulages, walnut stain and graphite, 1950. In the collection of the artist. 65 × 50 cm. (Right) "Still Life with Glass, Apple, Playing Card, and Package of Tobacco," pencil drawing by Pablo Picasso, 1913. In the Lydia and Harry Lewis Winston Collection, Birmingham, Michigan. 23.8 × 31.0 cm.



Eastern drawing.
(Left) "The Merchant and the Ascetic," Mughal drawing with colours, early 17th century. In the Smithsonian Institution, Freer Gallery of Art, Washington, D.C. 10.3 × 9.3 cm. (Right) "Woodcutter Gazing at Waterfall" (detail), by Hokusai, ink and colour on paper scroll, 1798. In the Stanford University Museum of Art, California. 29.7 × 39.0 cm.

of a precise and expressive line constituted the basis for Persian and Indian (both Mughal and Rājput) miniature paintings, which show people in landscape or in relation to buildings.

Japanese art tended to follow that of China until the early 19th century, when the popular colour print was introduced. In the graceful feminine gestures of Utamaro's work, the Oriental love of flowing contour is manifest, his lines varying in width and density. Hokusai's drawings of social life in a humorous, almost grotesque vein reveal his complete command of the expressive line. (Ed.)

BIBLIOGRAPHY. JOSEPH MEDER, *The Mastery of Drawing*, trans. and rev. by WINSLOW AMES, 2 vol. (1978; originally published in German, 1919; 2nd ed., 1923), a voluminous work that remains the basic treatment of the history and techniques of drawing. Another treatment, more concise in every respect, is HEINRICH LEPORINI, *Die Künstlerzeichnung*, 2nd ed. (1955). ARTHUR E. POPHAM published an introduction to drawing in *A Handbook to the Drawings and Watercolours in the Department of Prints and Drawings of the British Museum* (1939), based on the ample materials held by the British Museum. WALTER KOSCHATZKY, *Die Kunst der Zeichung: Technik, Geschichte, Meisterwerke* (1977), is a survey of the history, functions, and techniques of drawing, from the beginnings to modern art, based on excellent examples chosen mainly from the Graphische Sammlung Albertina in Vienna. CHARLES DE TOLNAY in *History and Technique of Old Master Drawings* (1943, reprinted 1972); and JAMES WATROUS in *The Craft of Old-Master Drawings* (1957), deal, from different points of view, with the history and techniques of the old masters; while HERIBERT HUTTER in *Drawing: History and Technique* (1968; originally published in German, 1966), stresses the artistic function of drawing and includes modern works. DANIEL M. MENDELOWITZ, *Mendelowitz's Guide to Drawing*, 3rd ed. rev. by DUANE A. WAKEHAM (1982), provides a historical résumé, with reference to the artistic elements and technical means of drawing; in the supplement to the 1st ed., *Drawing: A Study Guide* (1967), he offers practical instructions for drawing techniques and their application; as does ROBERT BEVERLY HALE in *Drawing Lessons from the Great Masters* (1964, reprinted 1974). JAKOB ROSENBERG illustrates the possibilities of drawing in *Great Draughtsmen from Pisanello to Picasso*, rev. ed. (1974), with samples from the works of eight great artists. *Great Drawings of All Time*, ed. by IRA MOSKOWITZ and VICTORIA THORSTON, 5 vol. in 6 (1962–79), contains a summary with comments by leading authorities. M.W. EVANS, *Medieval Drawings* (1969), is useful for the early history of the art of drawing; PAUL J. SACHS, *Modern Prints and Drawings: A Guide to a Better Understanding of Modern Draughtsmanship* (1954), for more recent developments. HERMANN BOEKHOFF and FRITZ WINZER, *Das grosse Buch der Graphik* (1968), gives the history of the 24 best known collections, with comments by the various curators and the basic catalog of each collection. Interesting information can be found in catalogs of many exhibitions and collections, such as BERNICE ROSE, *Drawing Now* (1976), which discusses contemporary types of drawing. The number of detailed investigations in regard to individual countries, periods, and artists is too large to be listed in this bibliography. One that can be especially recommended, however, is EDWARD J. OLSZEWSKI, *The Draftsman's Eye: Late Italian Renaissance Schools and Styles* (1981). LUIGI GRASSI, *Storia del disegno* (1947), is very valuable for the role of drawing in the historical theories of art, including the elucidation of the original sources for further study. Unsurpassed in method and fundamental for an intensive study of this subtle theme is BERNHARD DEGENHART's essay "Zur Graphologie der Handzeichnung," in *Jahrbuch der Hertziana*, vol. 1 (1937).

(H.R.H.)

Dress and Adornment

It is not possible, in an article of this length, to discuss the immense variety of garments and ornamentation worn by human beings throughout the world from prehistoric until modern times. Therefore, the following types of attire will not be treated here: ecclesiastical dress; military dress; academic, trade, or professional dress; and the national or regional costumes of peasant or primitive peoples. What will be considered in some detail is the chronological development of fashionable dress and decoration—that is, the attire selected and adopted by the leading members of a society. This is not an arbitrary decision but rather one reflecting the long-standing fact that in any group of people—whether constituting a small community or a great, influential nation—it is those members with wealth and, consequently, power at any given time who influence, and even dictate, the fashions to other, lesser members. The discussion does not concentrate solely on clothing but also covers, when appropriate, features of coiffure, head coverings, footwear, accessories, and cosmetic beautification. In addition, the nature and purposes of dress and some of the specific social, political, economic, geographic, and technological factors influencing changes in fashion, as well as the uses, forms, styles, materials, and techniques that have characterized jewelry throughout its 40,000-year history, are also treated.

For coverage of related topics in the *Macropædia* and *Micropædia,* see the *Propædia,* section 629, and the *Index.*

This article is divided into the following sections:

DRESS

The history of Middle Eastern and Western dress

ANCIENT EGYPT

Modern knowledge of ancient Egyptian dress derives from the ample evidence to be seen in the wealth of wall and sarcophagus paintings, in sculpture, and in ceramics; few actual garments have survived. Such illustrative material is depicted clearly and colourfully, but care must be taken in interpreting the designs too literally, partly because the art is frequently stylized but also because the artists were bound by tradition and their representation of dress often lagged far behind the actual changes of fashion.

Egyptian fabrics

The chief textile to have been preserved is linen, which has been found in graves dating to Neolithic times. Flax culture dates from very early times, and, in fact, the Egyptians believed that the gods were clothed in linen before they came to earth. Wool was more rarely employed, and sericulture had not yet extended as far west as Egypt. The technique of using mordants in the dyeing processes was slow to come to Egypt, so most garments were white. Colour was provided by jewelry in which semiprecious stones were widely incorporated. Among the most common types, the characteristic deep, decorative collar, worn by both sexes, was introduced early. These brightly hued bands were made of embroidered and beaded materials and set around the neck and shoulders either on bare skin or on top of a white cape or gown.

Skins of various animals were utilized. These were sometimes simply raw hides, which have survived only rarely, but the Egyptians became skilled at curing the skins to become leather by the tawing method—that is, by the use of alum or salt. Tawing yields a white, stiff leather that may be dyed various colours. Later they adopted the tanning method, employing oak galls for the purpose. Leather was used widely in dress for footwear, belts, and straps.

During the 3,000 years of the Egyptian culture, costume changed comparatively little and very slowly. It remained a draped style of dress, the garments consisting of pieces of material held in place around the body by knots tied in the fabric and by waist belts, sashes, and collars. Little sewing was needed, being confined generally to side seams and, in later years, to armholes. This draped type of dress conformed to that of other civilizations in the Mediterranean and Middle Eastern region such as Greece, Rome, and Mesopotamia but differed from the more Oriental styles of Persia, India, and China, where people wore more fitted, sewn garments based upon coats, tunics, and trousers. Ancient Egyptian dress for both sexes was confined to loincloths, a type of vest or shirt, capes, and robes.

Over the years the style of these garments slowly evolved and became more complex; a greater number were worn either in combination with or on top of one another. During the Old Kingdom (its capital at Memphis), which lasted until about 2130 BC, dress was simple. Men wore a short skirt tied at the waist or held there by a belt. As time passed, the skirt became pleated or gathered. Important people wore in addition a decorative coloured pendant hanging in front from the waist belt as well as a shoulder cape or corselet partly covering their bare torso. A sheath-like gown was typical of feminine attire. This encased the body from the ankles to just below the breasts and was held up by decorative shoulder straps. Woolen cloaks were worn for warmth by men and women.

Figure 1: Woman wearing sheathlike gown held up by shoulder straps, typical of Egyptian dress of the Old and Middle Kingdoms. Painted wood statue from the tomb of Meketre, Dayr al-Baḥrī, Egypt, 11th dynasty (2081–1938 BC). In the Egyptian Museum, Cairo.

Middle Kingdom styles

Under the Middle Kingdom, based on Thebes, which prospered until about 1600 BC, the masculine skirt could be hip- or ankle-length. More material was now used, making the garment fuller, such fullness being concentrated in the centre front; and the pendants became more elaborate and ornamental. A cape might be draped around the shoulders and knotted on the chest. Late in the period a double skirt was introduced; alternatively, a triangular loincloth might be worn under a skirt.

Hirmer Fotoarchiv, München

Figure 2: Egyptian dress of the New Kingdom, 18th dynasty. King Tutankhamen wearing a double skirt, long and full, with the upper one doubled and gathered in front; Queen Ankhesenamen in a draped robe tied at the breast and leaving the right arm free. Detail from the back of the throne of Tutankhamen (reigned 1333–23 BC). In the Egyptian Museum, Cairo.

The most elaborate dress for both sexes was to be seen under the New Kingdom from about 1539 BC until the Egyptians were conquered successively by the Assyrians (671 BC), the Persians (525 BC), Alexander the Great (332 BC), and finally Rome (30 BC). During these later years Egyptian dress was strongly influenced by that of the conquerors. New Kingdom dress was more complex than theretofore. The garments were of similar type but were composed of larger pieces of material; draping became more complicated and ornamentation richer. A robe or gown was now worn by important persons of both sexes. It consisted of a piece of fabric measuring 5 feet by 4 feet (1.5 metres by 1.2 metres) that was draped and held in place by pins and a waist belt, creating wide, elbow-length sleeves. There were many ways of draping the material, but with most methods all the pleats and folds seemed to be gathered around a single point at the waist. The cape, decorative collar, skirt, and pendant girdle also continued to be worn. Foci of bright colour were provided by the deep collar and pendant apron. Embroidered and carved ornamental motifs included especially the lotus flower, the papyrus bundle, birds in flight, and many geometric forms. Sacred emblems such as the scarab beetle and the asp were worn by priests and royalty.

Children were dressed, as in most of the history of costume everywhere, as miniature versions of their parents, although they are often depicted wearing little at all—not surprising considering the climate of Egypt. Servants also were almost naked, as were labourers in the fields, who are depicted clad only in a loincloth.

Wigs

Heavy wigs or a padding of false hair, worn by both men and women, are known from an early period. They served not only as an adornment but also to protect the wearer's head from the burning rays of the Sun, thus in a way acting as hats. Semicircular kerchiefs, tied by the corners at the nape of the neck under the hair, were sometimes worn to protect the wig on a dusty day. Wigs were dressed in many different ways, each characteristic of a given period; generally speaking, the hair became longer and the arrangement of curls and braids—set with beeswax—more complicated as time went on.

The earliest records indicate that the Egyptians grew hair on their chins. They frizzed, dyed, or hennaed this beard and sometimes plaited it with interwoven gold thread. Later, a metal false beard, or postiche, which was a sign of sovereignty, was worn by royalty. This was held in place by a ribbon tied over the head and attached to a gold chin strap, a fashion existing from about 3000 BC to 1580 BC.

Many people went barefoot, especially indoors, but people of rank are depicted outdoors in sandals made from palm leaves, papyrus, or leather.

Cosmetics were extensively applied by both sexes, and considerable knowledge of their use is available because of the Egyptian custom of burying comforts and luxuries with the dead. Examples both of the cosmetics and of the means of making, applying, and keeping them may be seen in museums, especially in Cairo and London. The Egyptians applied rouge to their cheeks, red ointment to their lips, and henna to their nails and feet, and ladies traced the veins on their temples and breasts with blue paint, tipping their nipples with gold. The chief focus of makeup was the eye, where a green eye shadow (made from powdered malachite) and a black or gray eyeliner was applied; the latter substance, called kohl, was manufactured from, among other materials, powdered antimony, carbon, and oxide of copper.

MESOPOTAMIA

Ancient Mesopotamia was situated in the area of land that is defined by the two great rivers the Tigris and the Euphrates and that is contained within modern Iraq. Several important cultures arose there, their empires waxing and waning successively as well as overlapping in time. Among the most prominent were the Sumerian, the Akkadian, or Semitic, the Assyrian, and the Babylonian.

Sumerian dress

The Sumerian civilization was established before 4000 BC and reached a high level of culture between 2700 and 2350 BC. In early times both sexes wore sheepskin skirts with the skin turned inside and the wool combed into

Figure 3: Skirt of tufted woolen fabric known as *kaunakes*, worn by Ebih-il, an official of the Temple of Ishtar in Mari, Syria. Statue of stone, bitumen, shell, and lapis lazuli, *c.* 2400 BC. In the Louvre, Paris.

Photograph, © Reunion des Musees Nationaux

decorative tufts. These wraparound skirts were pinned in place and extended from the waist to the knees or, for more important persons, to the ankles. The upper part of the torso was bare or clothed by another sheepskin cloaking the shoulders. From about 2500 BC a woven woolen fabric replaced the sheepskin, but the tufted effect was retained, either by sewing tufts onto the garment or by weaving loops into the fabric. Named *kaunakes* by the Greeks, this tufted fabric is shown in all the sculptures and mosaics of the period, as, for example, in the art from the excavations at Ur exhibited in the British Museum in London. At this time, also, long cloaks were worn, and materials for garments and head coverings included felted wool and leather. Men were generally clean-shaven. Both sexes seem to have often worn large wigs, as in ancient Egypt. Metalworking was of a high standard, as may be seen in the elaborate golden jewelry, which was encrusted with semiprecious stones and worn by both sexes: brooches, earrings, hair ornaments, and neck chains.

A different style of dress is evident in Mesopotamian sculptures dating after about 2370 BC. Both men and women were clothed in a large piece of material—most commonly of wool, though later also of linen—draped around the body over a skirt. This garment, similar to a shawl, was characteristically edged with tassels or fringe. The draping varied, but, for men at least, the fabric was arranged so that the fullness was at the rear, leaving the right, or sword, arm free. This newer form of dress had originated from farther north and east and was adopted by the Semitic people of Akkad under Sargon (the dynasty founded by Sargon lasted from *c.* 2334 BC to *c.* 2193 BC) and by the revitalized Sumerian culture in the years 2110–2010 BC.

The dress worn in Mesopotamia by the Babylonians (2105 BC–1240 BC) and the Assyrians (1200 BC–540 BC) evolved into a more sophisticated version of Sumerian and Akkadian styles. Ample evidence of this more elaborate draped costume can be seen in the large relief sculptures of the age. There were two basic garments for both sexes: the tunic and the shawl, each cut from one piece of material. The knee- or ankle-length tunic had short sleeves and a round neckline. Over it were draped one or more shawls of differing proportions and sizes but all generally fringed or tasseled. Broad belts held the shawls in position. Wool was the most frequently used material, in bright or strong colours. Decoration was rich, in allover patterns or in borders, carried out in embroidery or by printing. Motifs were chiefly geometric. Women wore a short skirt as underwear, men a loincloth.

Footwear for both sexes was made from fabric or soft leather in the form of sandals or boots.

Figure 4: Ashurnasirpal II (left), king of Assyria, with an elaborately dressed beard, wearing sandals and a full-length tunic decorated with embroidery and tassels. Alabaster relief from the palace of Ashurnasirpal II (reigned 883–859 BC) at Nimrūd, Iraq. In the British Museum.

Assyrian and Babylonian hairstyles and headgear

Care of the coiffure was very important for men and women among both the Assyrians and the Babylonians. The hair was grown long and carefully curled and ringleted, with false hair added if needed. Perfumes, oils, and black dye were used on the hair. Men grew long, equally carefully tended curled beards. A band of metal or fabric encircled the brow, or a woolen, felt, or leather cap shaped like a fez was worn. The royal headdress resembled a pleated crown or a mitre and had dependent lappets at the rear. Jeweled ornamentation to the costume was rich and heavy and of high quality.

THE AEGEAN: MINOAN AND MYCENAEAN DRESS

The Aegean region and in particular the island of Crete, which was inhabited from about 6000 BC, can be considered the cradle of western European culture. Settlers came to Crete from areas farther east—from Anatolia, North Africa, Syria, and Palestine. By 2500 BC the Cretan civilization was becoming established and, as a maritime people with extensive trade in the Mediterranean and the Middle East, was influenced by many sources. The Cretans created a society and a dress style of their own, one dissimilar from the earlier one of Egypt and the later of Greece. The greatest and most prosperous years were from 1750 to 1400 BC; this was the time of the building of the great palaces, notably Knossos, from where the remains of coloured frescoes, painted vases, and sculpture in marble, terra-cotta, and coloured ceramics have been excavated and are on display in the museums of Iráklion and Athens. Even finer and more complete frescoes have been preserved from the more recent excavations of the Minoan city on the island of Thera (now Santorin), an island largely destroyed in the cataclysmic volcanic eruption of about 1500 BC.

Cretan dress is characterized by its vivid colouring, elegance, and sophistication. It is also notable for the gaiety of feminine attire, typical of a society where women—unlike that of classical Greece—are depicted side-by-side

Figure 5: *Middle Minoan period dress.*
(Left) Woman wearing a bell-shaped skirt with flounces, an open jacket, and a diaphanous vest covering the breasts; her hair is intricately dressed with rows of small curls on the forehead and a chignon from which a ponytail falls. with men, taking part in all the activities of life and not relegated to the domestic background.

Men's garments were few. Chief of these was a loincloth of wool, leather, or linen, tightly belted at the waist and arranged as a short, elaborately decorated skirt. The belt was drawn tight to contrast the slender waist (presuming that the man had one) with the masculine breadth of chest. By 1750 BC women were wearing a long bell-shaped skirt, often in a series of flounces, over a loincloth; with this, they wore a bolero-like jacket that had elbow-length sleeves but was open in front, leaving the breasts bare. In the later period a boned bodice was worn, constricting the upper torso but accentuating the full, bare breasts above. (This is the first recorded example in Europe of corseting constriction of the figure and remained an isolated instance for centuries.)

Women's clothing

The Cretans liked bright colours, and their dress was vividly embroidered and decorated. The hair of both sexes was worn long, looped and braided and dressed with jewels, pearls, and ribbons. The Cretans bathed frequently, oiling their bodies afterward. Men were generally clean-shaven.

Outdoors both sexes wore sandals or shoes. In winter calf-length boots were adopted, and short woolen, fur-lined cloaks were fastened by pins around the shoulders.

With the collapse of the Minoan civilization in Crete about 1400 BC, a new culture arose on the mainland in the Peloponnese, notably in the maritime principalities of Mycenae, Tiryns, and Pylos. As the frescoes from the palace of Tiryns illustrate, the costume was similar but richer still.

ANCIENT GREECE

The long period of Greek culture is customarily classified into three segments. Up to about 500 BC is described as the Archaic period. This was the time when the several different civilizations of mainland and island Greece, Anatolia, and North Africa coexisted, the arts and costume of each influencing the others. The Dorians had invaded the Minoan kingdoms in Crete and the Peloponnese from about 1200 BC. They were a northern race from Illyria and a more primitive society than the Minoans. Modern knowledge of their dress is imperfect, but it seems to have been simple and crude. Woolen cloth, made from the flocks of local sheep, was employed. It was cut into squares of fabric and then pinned on the shoulders and bound around the body. The influence from Anatolia, where the inland climate was more severe, introduced hooded cloaks, banded leg coverings, and Phrygian caps with a point on top.

A later Archaic culture, the Ionian, then established itself in Greece. A more advanced society, the Ionians developed a higher-quality textile industry, producing finer materials in wool and linen that were more suited to a draped style of dress. In the 8th and 7th centuries BC the Ionians developed an extensive trading economy around the Mediterranean region from Gaul in the west to Libya in the east.

The 5th and 4th centuries BC were the years of the great Classical period of Greek culture, the time when a very simple but highly sophisticated and superb quality of work was achieved in the arts, especially in architecture, sculpture, and literature. This was the case with costume as well, the designs of which can be studied in detail from painted vases and sculpture. Classical Greek dress was a draped style, one in which there was little sewing. The garments for men and women were similar, consisting of oblong pieces of fabric in different sizes and materials, draped in various ways and held in place by ribbons and decorative pins. The dress was a totally natural one; there was no constriction and no padding. The simplicity of the dress was offset by the myriad ways of wearing it, a sophistication achieved by personal expression of the wearer.

Classical Greek dress

As time passed and finer materials (mostly linen) were produced, a further variety in draping was created by pleating, a treatment particularly in use for feminine wear.

Figure 6: Woman wearing the Greek chiton and himation. Marble statue from the Nereid Monument, Xanthus, Lycia, Anatolia, *c.* 400 BC. In the British Museum.

Reproduced by courtesy of the Trustees of the British Museum

The pieces of material were set into pleats, soaked in a thin starch solution, twisted and tied at the ends, then left in the sun to dry. This gave a greater permanence to the pleating.

The subject of colour in Greek dress is a difficult one. Neither sculpture nor vases (which are in black, red, and white) provide information. For a long time it was believed that the dress was largely white, and the reintroduction of the "Greek" style in Regency England and Directoire France presumed this from the marble sculpture. It is known, however, that buildings and ornament were painted in bright colours, and so it seems reasonable to believe that in the sunshine of Greece dress was also coloured; literary sources, moreover, report almost all types of colour being employed. In general, tunics were in lighter colours, cloaks darker. Decoration was most often by the classical ornament seen in architecture: the fret (key) pattern, flowers such as honeysuckle (anthemion), circles (paterae), and stripes.

The Hellenistic Age of Greek culture, dating from 323 BC and lasting until Greece became part of the Roman Empire in 30 BC, was a wealthier time, reflecting the wider boundaries of the Greek world resulting from the conquests of Alexander the Great. To the fine linens available in costume were added cotton from India and silk from China; thus the draped mode became more varied and elaborate.

The chiton

From classical times the chief garment was the chiton, a type of tunic made from one or two pieces of material hanging back and front, pinned on one or both shoulders, and girded. For men the chiton was usually knee-length and seamed up one or both sides. An ankle-length version was worn by women and for more formal wear by men. The simplest type of chiton was sleeveless, but later a sleeved version was made possible by using a much wider piece of material pinned at intervals at shoulder level, creating an elbow-length wide sleeve. A variation on the chiton style for both sexes was achieved by wearing a double girdle, one at waist level and one around the hips, the material being bloused out in between.

The peplos was a woman's garment. Made of one or two pieces of fabric, it hung from the shoulder pins to above or below the waist girdle. Alternatively, women used a longer piece of the chiton material and folded it over in front to hang in a similar manner.

Figure 9: Women's dress from the Hellenistic Age, showing the himation draped over the head and covered by a conical straw hat. Terra-cotta figurine from Myrina (near present-day Bergama, Tur.), 4th–3rd centuries BC. In the Louvre, Paris.

Alinari/Art Resource, New York City

There were two chief forms of cloak or wrap. The smaller one—the chlamys—was of dark wool and was worn pinned on one shoulder, usually leaving the right arm free. The larger wrap was the himation, worn by both sexes. Draped in many different ways, it covered the body and could be drawn up over the head. In sculpture, philosophers and statesmen are commonly depicted wearing the himation.

Knowledge of underwear is limited. Literary sources tell of a linen girdle worn to control the female figure and of a band to delineate the breasts. Men wore a loincloth.

Men's hair was long in the early years, but later it was cut short and carefully curled. Bleach was often used to make the hair fashionably blond; perfumes and pomades were applied. Beards were common until the time of Alexander. Most men were bareheaded, a hat being reserved for bad weather. There was a low-crowned, broad-brimmed style—the *petasos*—and a brimless cap, the *pilos*. Women's hair was long; it was usually curled and waved on the forehead and sides and drawn to a chignon at the nape. Many women wore wigs of different shades and decorated their coiffure with flowers, jewels, and fillets. They draped the head with the cloak and, in the Hellenistic period, sometimes perched a straw hat on top.

Footwear

Both sexes went barefoot indoors but outside wore leather sandals. Men also wore boots, which were laced up the front and might be fur-lined.

Greek jewelry was very fine and was, especially in the later centuries, worn in abundance. Both sexes used perfume, and women employed extensive makeup to give brilliance to their eyes, lashes, and cheeks.

ETRURIA

Cultural development came later to Italy than to the Aegean area. The Greeks colonized southern Italy and Sicily from the later 7th century BC, but it was the Etruscans who introduced a high standard of civilization, in the previous century, to the central region of the peninsula. They called themselves the Rasenna (though in Latin they were known as the Etrusci or Tusci). It is believed that they may have emigrated from Anatolia or possibly from farther east. They quickly developed their culture in their new land and, soon after 700 BC, they were living in an urban society capable of a high standard of building and visual arts. In dress, as in the other applied arts, they drew their inspiration and knowledge from a mixture of sources, chiefly Greek and Oriental.

Etruscan society appears to have had more in common with the Minoan culture than with that of Classical Greece. This was true, for example, of the position of women. Unlike the custom in Greece and Rome, where women were relegated to a submissive, domestic role, in Etruria women shared all the activities of life with men. The wealth of pictorial evidence that exists, chiefly the coloured frescoes and sculpture found in the great burial places such as the necropolis at Tarquinia, depicts women taking full part at banquets, dances, and concerts as well as attending racing, athletic, and other types of contests. These sources also indicate a close affinity of dress with the Minoan, illustrating sewn, fitted garments, bright colouring, rich decoration, and an abundance of beautiful jewelry—a craft at which the Etruscans excelled, especially in gold. Nevertheless, Etruscan dress, for both sexes, demonstrates a marriage between East and West, blending Eastern features from Egypt, Syria, and Crete with a later Ionian-style draped attire probably derived from the contemporary Greek colonists in southern Italy. Thus, Etruscans can be seen wearing both draped, pinned tunics and fitted, sewn ones, or such Greek styles as the chlamys, himation, or chiton in conjunction with footwear with Middle Eastern-style turned-up toes. Some Etruscan garments presaged later styles; for example, the *tebenna*, a semicircular mantle, was an early version of the Roman toga, and a decorative collar derived from Egypt anticipated a later Byzantine version.

Etruscan blend of Eastern and Western styles of dress

ANCIENT ROME

The Roman civilization lasted from the traditional founding of the walled city in the mid-8th century BC to the

Scala/Art Resource, New York City

Figure 10: Etruscan musicians wearing tunics, cloaks similar to the Greek chlamys, and sandals. Detail from a fresco in the Tomb of the Leopards, 5th century BC. In the necropolis at Tarquinia, province of Viterbo, Italy.

final collapse of the western part of the empire in AD 476. Until the 3rd century BC the Romans derived their culture from the Greeks and the Etruscans but after this gradually began to develop their own civilization and to expand their influence, taking over territory after territory—first that of the Etruscans, then Sicily, Carthage and North Africa, Greece in 146 BC, and Egypt in 30 BC. They went on to found the great Roman Empire, which by the 2nd century AD extended from Spain to the Black Sea and from Britain to Egypt.

The history of Roman dress is paralleled by that of their arts and architecture. They inherited their style from the Greeks, but, as the empire extended its borders, incorporating peoples of different customs, climate, and religion, a greater complexity became apparent in response to a greater variation of need. The original pattern had become a mutation. In costume, as in art, the trend was toward a more ornate, richly coloured, more varied, and, especially in the later days of the empire, very luxurious attire. Roman dress also reflected a distinct division of social class, with certain colours, fabrics, and styles reserved for citizens and important personages.

With the expansion of the empire and consequent wider trading possibilities came also the availability of more varied and elegant fabrics. Cotton from India and silks from the East were accessible to the wealthy, enriched by high-quality embroidered edging and fringing. Elagabalus (AD 218–222) was the first Roman emperor to wear silk. Later, looms were set up to weave silk, but China retained control of sericulture, exporting only silk thread or fabric, both of which were prohibitively expensive.

The art of dyeing and knowledge of the use of mordants was now more extensive. The famous dye of the classical world was Tyrian purple, so called because its centre of production was in the twin cities of Tyre and Sidon (now in Lebanon). The dye was obtained from small glands in the mollusk *Purpura* and was costly owing to the small size of the source material. Thus, the wearing of the purple was reserved for a few. (Although the name *Purpura* gave rise to the word purple, the colour was actually a crimson.) Under the empire, production sites were established in Crete, Sicily, and Anatolia. At Taranto in southern Italy a hill survives that is composed entirely of the shells of the *Purpura* mollusk.

The toga

The garment for which Rome is most famous is the toga. A large piece of material wrapped around the masculine body as a cloak, the toga served a similar function as the Greek himation, although the fabric was of quite a different shape. Under the empire, the toga acquired a special distinction because of its unique and complex method of draping and because, as a note of rank, its wearing was restricted to Roman citizens. The toga was not rectangular in shape like the himation but was a segment of a circle, measuring about 18 feet along the chord of the segment and about 5.5 feet at its widest point. It was made of wool and so was very heavy. To drape it, about five feet of the straight edge of the fabric was placed against the centre front of the body from ground level upward. The rest of the material was then thrown over the left shoulder and passed around the back, under the right arm, and once again over the left shoulder and arm. The right arm was therefore left free. The material could be pouched in front as well as drawn up over the head. Certain patterns and colours were worn by specific members of society.

The toga gradually became a ceremonial garment, and a great variety of other cloaks were worn by civil or military personnel. Some cloaks were hooded; many were like the Greek chlamys. They had a variety of names: *paenula, abolla, paludamentum, lacerna,* and so on. A less bulky, more manageable alternative to the toga was the *pallium,* a version of the Greek himation.

The basic masculine garment was like the chiton; it was called a *tunica.* Colours differentiated the social classes—white for the upper classes, natural or brown for others. Longer *tunicas* were worn for important occasions. About AD 190 the *dalmatic* was introduced from Dalmatia. This was a looser, ungirded style of tunic with wide sleeves.

Feminine dress was very like the Greek, with the Roman woman's version of the chiton called a *stola.* As time passed, women took to wearing several garments one on top of the other, while the garments themselves were made of finer fabrics and were more lavishly decorated. The feminine cloak, the palla, resembled the Greek himation.

Underwear for both sexes consisted of a loincloth—like

Alinari/Art Resource, New York City

briefs—and women also wore a breastband—the *mamillare*.

Footwear was based upon the Greek but was more varied. Apart from sandals, several styles of shoe and boot existed, once again the colours denoting social status.

Both sexes spent a great deal of time on their toilette, in bathing and using perfume and cosmetics. Face powder, rouge, eye shadow, and eyeliner were lavishly applied by upper-class women, who also attached beauty patches to their faces. Wigs and hair switches were commonly worn, and certain colours of hair were fashionable; for example, during the Gallic and Teutonic campaigns, blonde wigs made from the hair of captured slaves were in vogue.

ANCIENT NONCLASSICAL EUROPE

Animal furs and hides made up the chief garments during the Stone Age. They would be held to the body by a thong belt and by pins at the shoulder. Later such skins were sewn to give a closer fit. Finds from tombs and living sites indicate that the people had a fair knowledge of simple weaving, of sewing, and of how to dress skins. No actual garments have survived, however; remains include boxwood and bone combs, reindeer horn buttons and plaques, and decorative items such as necklaces and armlets of beads, amber, and ivory.

The advent of the Bronze Age varies from one part of Europe to another. The art of bronze working came to Italy from the Middle East and then spread westward to Britain and Scandinavia. During the years 1500–600 BC the arts of spinning and weaving were further developed; simple natural dyes were used; and decoration was by embroidery, fringing, and plaiting.

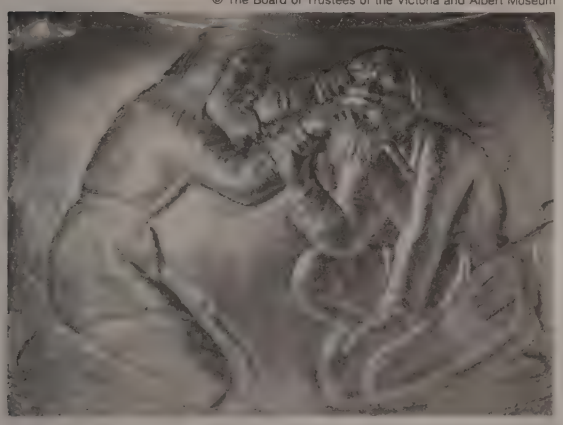

Figure 13: Scythian dress, consisting of tunics, trousers, and short boots. Detail from a replica of an electrum vase (original in the Hermitage, St. Petersburg), from the tomb at Kul Oba, near Kerch, Crimea, Ukraine, 4th century BC. In the Victoria and Albert Museum, London.

In Denmark, northern Holland, and Germany the peat bogs have preserved a number of actual, almost complete, Bronze Age garments; most of the garments, which were found at burial sites, are woolen items that were maintained in remarkable condition in oak log coffins. They include large semicircular cloaks, felt caps, tunics with leather straps and belts, and, for women, jackets and skirts with ornamental belts and hair ornaments. Many of these are on display in the National Museum in Copenhagen and the Schleswig-Holstein Museum of Prehistory and Early History in Germany. Bronze Age garments

A different type of dress was worn by the nomad peoples who roamed the European and Asian steppes between Manchuria and Hungary. Such groups, which included the Scythians, Cimmerians, Sarmatians, and Parthians, traveled immense distances on horseback, their attire being suited to their way of life. Both sexes wore similar garments consisting of a woolen tunic over a shirt and wide trousers. These garments were worn in layers one on top of another; they were fairly close-fitting but loose enough for comfort and for the practical needs of hours spent on horseback. Short boots were pulled up over the trouser bottoms and tied in place. These peoples also wore leather belts around their waists, and felted woolen caps kept their heads warm. Around 600 BC the Scythians lived in the region around the Black Sea and then gradually moved westward to Romania, Hungary, and Germany. Excavation of their burial sites in the Dnieper valley and near Simferopol, both in Ukraine, and in the Balkans has yielded both actual garments and a wealth of relief sculpture, vases, and plaques that illustrate Scythian dress.

The 6th-century BC Hallstatt culture of the Bavarian and Bohemian areas had an advanced life-style for its time. Finds from this early phase of the Iron Age, however, are chiefly weapons and jewelry. In the 4th century BC the Celtic peoples from central Europe invaded Italy and moved on to Britain, Ireland, and Spain. Finds of the Celtic culture, which consist largely of jewelry, toilet articles, and ornaments, illustrate both the high Celtic standard of craftsmanship, especially in metal, and the individual character of their design. Museums in many countries—notably Italy, Spain, Portugal, Ireland, Britain, and Czechoslovakia—display a wealth of such work.

Roman influence on the dress of the northern and western countries of the empire was strong until the early 5th century AD. This was to a certain extent, however, a two-way influence since, in the colder northern areas, the Romans found the indigenous dress styles of belted tunics with trousers or leg-banding more suitable than their own classical *tunica* and bare legs. Useful evidence of local attire in Britain, Gaul, and Germany is graphically illustrated on the two famous victory columns in Rome—that of Trajan and of Marcus Aurelius. This evidence is reinforced by the written accounts of Roman historians such as Cornelius Tacitus of the 1st century AD and Sidonius Apollinaris of the later years. Roman influence

THE PRE-COLUMBIAN AMERICAS

Archaeologists now believe that the Americas were first inhabited by people who crossed the Bering Strait from Siberia to Alaska some 25,000 years ago. This narrow strait is shallow and, for a considerable part of the year, frozen over, making such a route easy of access. Over many hundreds of years these peoples gradually spread throughout North and South America, reaching the southerly point of Tierra del Fuego about 9000 BC. At the time of their first encounter with European explorers, this population was composed of societies of many types and levels of achievement, extending from the Eskimo in the north to the North American Indians of the plains, the lakes, and the forests to such highly advanced cultures as the Inca, Maya, and Aztec farther south. The climatic variation over the Americas is immense, presenting almost every type possible in the world. Probably owing to the warmth of the central and southern areas, population density by the 15th century AD was much greater in South America

than in North; the total population is estimated to have been about 20 million in the south and just over 1 million in the north.

The North American Indians. Clearly the costume worn in these different areas varied as much as the climate. It was dictated not only by the weather but also by the materials available for clothing, the standard of culture of the individual groups and tribes, the terrain they inhabited, and the predators they faced. Even the North American Indians alone displayed considerable variety in their dress. There were, however, similarities in dress whether the tribes were of Woodlands or Plains Indians.

Few woven materials were made. The North American Indians wore mainly skins of any of the animals living in their area: deer, elk, buffalo, moose, beaver, otter, wolf, fox, and squirrel. They were highly skilled in tanning such skins by the chamoising process, in which oil is used. The Indians employed animal oils, particularly those found in the brains of the animal, especially deer, so producing a softly textured material that they then dyed in brilliant colours. They made use of the entire skin, adapting the garment to the shape of the animal and wearing it draped and sewn only minimally; the legs, paws, and tail were left attached and hung down as decoration. Two skins were often used for a woman's dress or man's tunic, one back and one front. They pierced the skin with bone awls (not needles with eyes) and threaded edges together with animal sinew. Decoration was by porcupine-quill embroidery, the quills being softened by chewing and then dyed. Garments were also decorated by fringed edging.

Men wore a breechclout and women a short skirt. In warm climates an apron back and front was added to this, along with a cloak or poncho in bad weather. In cooler areas men wore a loose hip-length tunic and thigh-length leggings, the latter tied to the waistband of the breechclout. Women wore a long dress and short leggings.

Hairstyles

Hair was carefully tended by both sexes. For the men there were many, varied styles; in some areas hair was grown long and plaited, in others it was worn loose. Some styles were dramatic, consisting of, for example, a ridge of hair sticking up along the crown of the head, extending from the forehead back, with the remainder of the head shaved. (This style was revived in punk coiffures of more modern times when it was called the Mohawk or *Mohican.*) Animal hair and feathers were added to many hairstyles. The famous feather bonnet headdress, with buffalo horns and headband, was the warbonnet, into which might also be incorporated ermine tails and quillwork. Women's hair was long, worn loose or plaited, and held in place by a headband.

The moccasin was the traditional Indian shoe, a style introduced into Europe in the 20th century. It was made from one piece of soft leather, which enclosed the foot, with no added sole or heel. It was seamed to an inset decorative piece on top of the instep. The leather was then folded over at the back.

Facial and body hair was often plucked out with tweezers; and both face and hair were painted. Red pigment was frequently used to paint the body. Both sexes tattooed their bodies, sometimes all over. Colour was then impregnated into the tattooed skin; bright red was most often used for this.

The Eskimo. The Eskimo settled in Alaska about 1000 BC and gradually spread across the northern coastal region of Canada and as far east as Greenland and Labrador. Their clothing, which was adapted to the Arctic cold, had much in common with that worn in the Siberian Arctic areas from whence they had come. This clothing was, like that of the North American Indians, made from animal skins, but, because of the climate, it was sewn and tailored to the body to keep out the wind. The fur or pelt of the animal was retained and usually worn inside. Thread was of animal sinew and needles of bone or ivory. Like the North American Indians, the Eskimo used all available animal skins: polar bear, deer, caribou reindeer, antelope, dog, fox. They also used birds—the skin for clothing, the feathers as decoration. Sealskin was ideal for boots, the fur turned inward.

Both sexes wore the same type of garments: a hooded tunic or coat, trousers, and boots. The hooded tunic was variously named in different areas. Two of these—the parka of the Aleutian Islands and the anorak of Greenland—have become essential items of modern dress. In winter two or more tunics might be worn; these were known as *kuletak.* Trousers were *kallik.* and boots *kamik.*

Untanned, untreated animal skin suffers from putrefaction and does not last too long. To tan leather, the exterior layer of fur and blood vessels must be removed, as well as the inner layer, leaving the central dermis to be tanned to become leather. Unlike the North American Indians, the Eskimo needed to retain the fur layer, so they scraped off the inner layer and treated the dermis by soaking and manipulation. They soaked it in a liquid of urine and ash. The women, who did this work, chewed the skin to soften it. They also made waterproof capes from the intestines of seals and walrus.

The Aztec, the Maya, and the Inca. At the opposite end of the climatic scale were the cultured peoples of central and southern America who flourished during the European Middle Ages; these were, notably, the Aztec, the Maya, and the Inca. The Aztec and Maya lived in a hot climate and so wore a minimum of clothing, although their garments were brightly coloured and decorated. The Aztec settled in Mexico about the 12th century. Their capital city, Tenochtitlán, which they established in the 14th century, was on the present-day site of Mexico City. The men wore loincloths, the women tunics and skirts, all made from cotton. Ornamental cloaks were retained chiefly as garments of rank rather than of necessity. The decoration of Aztec costume was chiefly by exotic plumes, but fur also was used. They wore a great deal of jewelry, mainly of gold.

Aztec dress

The Maya came to Guatemala about 800 BC and spread into the Yucatán Peninsula. Their culture, which was then a Stone Age one, flourished chiefly between AD 250 and 900. They also wore few garments: a loincloth for men and a cloak when needed; women wore a loose sleeveless dress or blouse and skirt. Cotton and sisal were cultivated, with the women spinning and weaving these fibres. The Maya also developed a method of tie-dyeing the yarn and of weaving patterns using bright colours for dyes. Embroidered decoration also was practiced.

Cotton fabrics were mainly reserved for upper-class wear, as were beautifully decorated leather belts and sandals. For the ordinary people, tapa—a cloth derived from tree bark as in Polynesia—was made. An important part of

Figure 14: Mayan men of the upper class wearing decorated loincloths and ornamental headdresses. Detail from a polychrome vase. Quiché Maya, from Nebaj, Guat., Late Classic Period (6th–10th century). In the British Museum.

Mayan decoration was provided by feathers from the birds of brilliant plumage, which were available and which were skillfully incorporated into the weaving processes. The feathers were also widely used in the ornamentation of headdresses. The long, iridescent tail feathers of the quetzal were especially prized, as they were also in Aztec dress.

The Inca came from the valley of Cuzco in the high mountains of Peru. During the 15th century they established a powerful empire of some five million people in the area of what is now Peru, Bolivia, and Ecuador and extending into parts of Argentina and Chile. They also adopted a brightly coloured attire decorated by feathers—indeed some of their fine cloaks were made entirely of feathers woven into a cotton fabric base. They kept herds of llamas for wool and hunted animals for fur; the chinchilla provided the most beautiful of their pelts.

The actual garments were simple: a basic loincloth for both sexes and, over this, a short tunic for men and an ankle-length dress for women. The poncho was the most usual cloak. People went barefoot or wore sandals. They also frequently went bareheaded or, in bad weather, adopted a woolen cap or turban.

THE MIDDLE EAST FROM THE 6TH CENTURY

The style of costume worn over this large and not very well-defined region has been remarkably constant for centuries. This is partly because it has evolved as one suited to carrying out hard work on the land under considerable extremes of climate, serving as a protection to the body against heat, dust, and blazing sunshine, and partly because the wearing of traditional clothing has been accepted and supported by Muslim countries. The actual garments worn are loose-fitting ones that cover, even envelop, much of the body. The names of these garments vary from country to country, but the similarity is clear. Likewise the materials from which they were, and still are, made vary according to what is available. In general, linen, cotton, and wool are the norm, but the well-to-do have always worn garments made from rich fabrics with a silk base. Several of the most famous of these materials originated in this area, including baldachin, the richly decorated fabric with a warp of gold thread and a weft of silk, named after the city of Baghdad, and damask, named after Damascus (in Syria), from whence this richly patterned silk fabric came.

Middle Eastern fabrics

A number of the traditional garments were originally derived from ancient cultures in the region, particularly from Persia (now Iran) and from farther east in India, Mongolia, and Asian Russia; the caftan is one such example. Still worn in comparatively modern times, this is an open, coatlike garment termed, in ancient Persia, a *candys* or *kandys*. Also worn extensively in the cooler climates of Mongolia and China, the style extended westward to become, eventually, the fashionable dolman of the late Ottoman Empire.

The spread of the characteristic costume of the Middle East was due in large part to the Arabs. These were people of the Arabian Desert who, by the 6th century AD, led a stable, rural life in the border areas of Yemen, Syria, and Iraq but who, in the interior region, were largely Bedouin nomads raising camel herds for a living. By AD 750 the Arab empire extended from Spain and Morocco in the west to the Caspian Sea and the Indus River in the east. The chief garments worn at that time were a loose shirt, chemise, or robe; a draped cloak; wide, baggy trousers; and a headcloth or turban. Remarkably similar versions of these may still be seen on the streets of Cairo, Istanbul, or Damascus.

The simple basic garment for both sexes was a loose, long shirt, chemise, or tunic, which often had long sleeves. Over this men wore a robe or mantle of various types. The *aba* or abaya was of ancient origin and is mentioned in the Bible as the attire of Hebrew prophets. It was traditionally made of heavy cream-coloured wool decorated with brightly coloured stripes or embroidery. A voluminous outer gown still worn throughout the Middle East in the Arab world is the jellaba, known as the *jellabah* in Tunisia, a *jubbeh* in Syria, a *gallibiya* in Egypt, or a *dishdasha* in Algeria. The garment generally has wide,

Figure 15: Egyptian agricultural worker wearing traditional jellaba, Jordan Valley, Jordan.

long sleeves, and the long skirt may be slit up the sides; some styles are open in front like a coat or caftan. Outer gowns or cloaks sometimes incorporated head coverings. These included the haik, which was an oblong piece of material (generally striped) that the Arabs used to wrap around their bodies and heads for day or night wear; the material measured about 18 feet by 6 feet. A similar mantle was the burnous, a hooded garment also used for warmth day or night.

The loose, baggy trousers traditional to the Middle East, as well as to the Balkans and Anatolia, are still widely worn by both sexes. The garment is believed to have originated in Persia, and it is presumed that the Arabs saw it there when they invaded that country in the 7th century. The trousers, called *chalvar, chalwar,* or *şalvar* according to the country where they were worn, measured about three yards across at the waist and were drawn tight by cords. The full, leg portion was tied at each ankle. A broad sash then encircled the waist, on top of the *chalvar.* Worn in this way the garment was ideal for working in the fields because it allowed freedom of movement and protected the lumbar region of the spine, especially while bending, from chills. For centuries the garment has also been adopted by men in the fighting forces. Cotton is the usual material for working attire, but fashionable ladies wear such a *chalvar* made from a brocade or silk fabric over linen drawers.

The *chalvar*

The tradition for women to cover themselves from head to toe and veil their faces when they go out in public is an old one, predating Islām in Persia, Syria, and Anatolia. The Qur'ān provides instructions giving guidance on this matter but not a strict ruling. It has been the rigidly male-dominated world of the Middle East that has insisted on the strict veiling of women in public. The enveloping cloaks worn by women for this purpose are similar to one another and often incorporate a mesh panel through which women may peer at the world outside. The most common names for this garment are chador, *chādar, chadri, çarşaf,* and *tcharchaf.*

The characteristic masculine Arab headdress has been the kaffiyeh. It is still worn today, although it may now be accompanied by a Western suit. Basically, the kaffiyeh is a square of cotton, linen, wool, or silk, either plain or patterned, that is folded into a triangle and placed upon the head so that one point falls on to each shoulder and the third down the back. It is held in place on the head by the agal (*igal, egal*), a corded band decorated with beads or metallic threads.

Footwear was in the form of sandals, shoes, or boots, with the toes slightly turned up. Women traditionally wore decorative wooden pattens called *kub-kobs* to walk about in muddy unpaved streets.

THE BYZANTINE EMPIRE

In AD 324 the Roman emperor Constantine decided to rebuild the great city at Byzantium, then a Greek centre, sited strategically on the Bosporus, whose narrow waters connecting the Mediterranean and the Black Sea acted as a gateway between West and East. Constantine called his city New Rome; it was later renamed Constantinople (now Istanbul) in his honour. After the collapse of the western part of the Roman Empire, which was based in Rome (and later Ravenna), in the 5th century, Constantinople became the capital city of a Christian-dominated empire whose extent fluctuated considerably until its own collapse to the Turks in 1453.

Owing to the site of its capital city, the Byzantine Empire was subject to a complex of influences that were nowhere more marked than in the dress of its ruling classes. Over the centuries there were two notable periods of wealth and prosperity, and these, as always, were reflected in costume. The first period was in the time of the emperor Justinian, who reigned from AD 527 to 565. Until this time the influence of Rome was still strong, and dress styles tended to be draped in the fashion of the later years of the empire. There were differences, however, derived in part from Persian and Anatolian designs, that introduced more Eastern forms of dress, such as sewn, closer-fitting garments and richer ornamentation and jewelry.

Because of its success as a trade centre between East and West under Justinian, the Byzantine Empire became extremely wealthy. This wealth, allied to the love of richness and to the high standard of Arabic and Oriental craftsmanship available, led to a costume of magnificent splendour that became the envy of the known world. Luxury fabrics from Asia, Syria, and Egypt became available in quantity and were utilized, despite the high cost, by the leading members of society.

Introduction of sericulture

The domestic textile industry was also stimulated, its development greatly aided by the introduction of sericulture into Constantinople. The Chinese had guarded secrets of the manufacture of silk for hundreds of years, but by about 1000 BC silkworm culture and silk manufacture had been established in northern India, and the knowledge later percolated through to Korea, Japan, Persia, and Central Asia. Justinian had tried early in his reign to divert the silk trade from its route from Persia but without success. He was then presented with a tremendous opportunity when two Persian monks, who had worked as missionaries in China and had studied the process of sericulture and the weaving of the filaments, agreed to smuggle this knowledge, as well as the necessary silkworm eggs, to Constantinople in exchange for a large monetary reward. Silkworms flourished in Constantinople, and the authorities there, like the Chinese and others before them, guarded the secrets of the process and controlled their monopoly in Europe until, inevitably, in the early Middle Ages, the knowledge and means were once more disseminated, this time to Anatolia and Sicily and from there gradually to Italy and France.

During Justinian's reign, Byzantine textile manufacturers produced beautiful, glamorous fabrics, mainly of silk interwoven with gold and silver metallic threads and interspersed with pearls and jeweled embroideries. The use of these heavy lustrous fabrics gradually altered the style of dress; the stiff, ornate materials lent themselves to a simpler cut with only a few folds to break up the often allover, large-motif designs. For both men and women a more fitted, sewn tunic, cinched at the waist by a richly decorated wide belt and hanging straight to knee or ankle, replaced the Roman draped *tunica*. A rich, deep decorative collar, like the preceding Egyptian and Etruscan versions, covered the shoulders. The influence of the Christian church could be seen in the fact that the limbs were generally covered by long, usually fitted sleeves and cloth or silken hose. Cloaks, pinned at the shoulder, were worn outdoors. Imperial dress was characterized by the extensive use of purple and gold. Garments for the wealthy were vividly coloured in reds, yellows, and greens. Such attire is depicted in the 6th-century mosaics and the Ravenna churches of San Vitale and Sant'Apollinare Nuovo.

Figure 16: Byzantine dress, characterized by rich, vividly coloured fabrics and elaborate jewelry, as seen in this depiction of Empress Theodora and her retinue. The men at left wear long-sleeved, fitted tunics under cloaks pinned at the shoulder. The women's fabrics are richly patterned, some interwoven with metallic thread. Theodora, at centre, wears regal purple and gold, with bejeweled headdress and collar. Mosaic from the church of San Vitale, Ravenna, Italy, *c.* 526–548.
Scala/Art Resource, New York City

The second period of expansion and prosperity came between the 9th and 11th centuries. Court dress became richer than ever, encrusted with jeweled embroideries and dyed in deep colours, especially purples and reds. Imperial dress included a long panel of gold-embroidered material, which was wrapped around the body with the end hung over one arm. The classical line had completely given place to an Eastern form of dress. For example, the caftan had been adopted as formal wear. Open down the centre front, this coatlike garment was shaped to fit at the back. For both sexes the caftan was accompanied by trousers, not full like the Middle Eastern *chalvar* but more elegantly and closely cut, especially on the lower limbs where they were tucked into boot tops or worn over shoes.

The caftan

Byzantine dress strongly influenced that of eastern Europe, especially the Balkans and Russia. Some of the bejeweled silk formal garments were gradually adopted by the church to become vestments in the Middle Ages.

Men tended to prefer leather boots in footwear, black for normal use and red at court. Women sometimes wore sandals but more often were found in soft, ankle-height shoes, brightly coloured and embroidered.

Masculine hairstyles were short, and men were mostly clean-shaven. Outdoors they adopted the Phrygian cap or a hood. Ladies wore veils and often encased their long hair in a silk cap or a pearl net. Elaborate jewelry was characteristic of all Byzantine dress of the upper classes. Perfume was liberally applied but cosmetics less so.

MEDIEVAL EUROPE

The dress of Europeans during the years from the collapse of the western part of the Roman Empire in the 5th century to about 1340 was slow to change and was largely standardized over a wide area. Regional variations in climate, social customs, and relative wealth brought only a limited differentiation in dress.

Clothes for men and women were similar, being sewn albeit crudely and loosely cut. A shirt or chemise and braies—that is, a roughly fitting kind of drawers—constituted underwear. These were of a natural coloured linen. The shirt was hip-length for men, longer for women. It had a round neck, slit in front for ease of donning, and was tied with a drawstring; the braies were similarly fastened at the waist. On top of this was worn one or more tunics—knee- or ankle-length for men and ground-length

for women. The tunic had a round neckline and long sleeves cut in one with the garment; it was loose fitting but girded at the waist. Tunics were made from coloured linen or wool and were decorated with embroidered bands at the neck, wrists, and hem. Legs were covered with ill-fitting hose, these were cut from cloth in two vertical sections and sewn together. They were held up by banding or garters.

Thirteenth-century dress was noted for its plainness. There was little or no decoration, and garments were unbelted. A sleeveless surcoat was generally worn over the tunic. This had derived in the late 12th century from the tabard, a garment worn by crusading knights over their armour to prevent the sun from reflecting off the metal and making them visible to an enemy. The surcoat, which was worn by both men and women, often had slits (called fitchets) on each hip so that the waist belt underneath with purse attached could be reached without fear of thieves.

Men's hair might be long or short; some men were clean-shaven, while others had beards. Ladies wore their hair long, parted in the centre, and plaited and then pinned up at the sides; they then pinned a white linen neckcloth to the plaits on each side (the wimple), concealing the hair, and on top of this wore a veil, a white linen crown, or a pillbox cap. Such headdresses were known by a variety of names, including barbette, fillet, and *touret*.

Introduction of tailored garments

Toward 1350 a great change occurred in costume. Clothes were tailored to fit and display the human figure instead of obscuring it. As with most fundamental events in human history, this had more than one underlying cause. It was due partly to the gradual improvement in the ability to tailor garments; partly to the availability of a higher quality and greater variety in fabrics, which were now reaching the West from Italy and farther east; and partly to society's readiness to receive such developments. The most important reason was the spread of the Renaissance movement from Italy. A movement both spiritual and secular, the Renaissance was dedicated to reviving classical concepts and to celebrating the dignity and importance of man. This was expressed in costume by the beautification and display of the human figure.

Statues on the right-hand portal of the west facade of Strasbourg cathedral in France, *c.* 1280–1300.

During the remainder of the medieval period, men were the more gloriously appareled of the sexes, and so it was men whose bodies were more specifically delineated. In the 14th century this concept was initiated by the establishment of the fitted tunic, which was cut into four sections that were seamed at the centre back and at the sides and fastened with buttons centre front. By 1340–45 this tunic was hip-length with a heavy leather belt decorated with metal and jeweled brooches encircling the hips only a few inches above the hem. Sleeves were elbow-length, ending in a cuff from which a two- to three-foot streamer, called a tippet, depended. The undertunic, of similar cut, had long sleeves, buttoned to fit closely from elbow to wrist.

The hose were now fitted more closely also. They were cut from velvet, silk, or woolen cloth in four sections and extended from the foot to the upper thigh, where they were attached by points (laces with metal tag ends) to the lower edge of the undertunic. By 1370–80 the hose grew longer to become tights and were laced by points all around the body to the by-then waist-length undertunic. As outer tunics also became increasingly short in the early 15th century, a codpiece became necessary. This was a bag covering the front opening between the two legs and was attached by points to the hose. (The name derives from the medieval term cod, meaning bag.)

Ladies' gowns also were affected by current events. The neckline was lowered and was cut straight across at shoulder level. The bodice, which extended to the hips, was fitted like the men's tunic, and a similar heavy belt encircled the hips. Below the hips the skirt was gored, very full, and long. Sleeves resembled men's styles. Another gown, called a sideless surcoat, was often worn on top. This had no sleeves but had a very large armhole to display the gown beneath; the armholes and a front panel known as the plastron were often trimmed with fur.

Parti-colouring

There were several new forms of decoration at this time. One was parti-colouring, in which all garments, including hose, could be of one colour down one side and a different hue on the other, the dividing line thus delineating the form of the figure. Counterchange designs—heraldic, floral, or geometric in motif—were introduced where the ground colour and design colour were interchanged. Edges of garments were cut into various shapes; these were called dagges (Middle English: dags).

During the 15th century these trends developed further. Men's hose became still better-fitting. Tunics were shorter, often only waist-length. Fabrics were richer and beautifully patterned. For older men, for whom displaying the figure was less suitable, a long gown was introduced to wear over the tunic. At first (14th century) full and long like a dressing gown (the houppelande), the gown gradually became more tailored and formal, with vertical pleats in back and front. All garments, for both sexes, were fur-edged and, often, fur-lined—for both warmth and appearance.

By the 15th century, styles, accessories, decoration, and fabrics were beginning to vary from area to area. The fashion-setter in the years 1430–75 was Burgundy, a duchy which then controlled Flanders and much of modern France. It was the wealthiest region, and the fabrics it manufactured—velvets, silks, gold and silver materials, and embroideries—were of the highest quality. After Burgundy's defeat in 1477 at Nancy, Italy became the fashion centre of Europe. Italian fabrics were equally beautiful but less heavy and with less fur. Colours were gay and bright, and the emphasis for both sexes was on an elegant, natural human form with a gracious ease of movement.

Men's hairstyles varied greatly during this long period. In general, they were short until the later 15th century, and men were mostly clean-shaven. The main head covering was the hood with an attached shoulder cape and a long extended point, or tail, known as a liripipe. By the 1420s a new way of wearing this hood was tried. The face portion was placed on the head, then the cape was arranged in folds like a cockscomb and tied into place with the liripipe, the end of which trailed over the shoulder (a style immortalized in jester's attire). This was an inconvenient arrangement and so a padded roll evolved—the

Figure 18: Fashionable mid-15th-century Italian dress. The men wear pleated, fur-trimmed tunics, fitted hose, and, on their heads, the roundlet and liripipe. The women are dressed in long gowns made from richly embroidered fabrics and a typical selection of the varied styles of headdress of the time, from turbans to heart-shaped designs. Detail from the "Adimari Wedding" cassone, Florentine, *c.* 1470. In the Accademia, Florence.

Scala/Art Resource, New York City

roundlet—with the separate shoulder cape sewn in place to one side and the liripipe to the other. Toward the end of the century, various styles of tall or broad-brimmed hats, decorated by coloured plumes, replaced the hood.

Women's headgear

Ladies' headdresses were extremely varied. Hair was still long, plaited, and coiled over the ears. These coils might be enclosed in metal mesh jeweled nets called cauls and were worn with a veil. In the 15th century turbans were fashionable—Byzantine style introduced in Italy—as were also steeple headdresses resembling dunce caps and, alternatively, shorter fezlike caps. All were made of rich fabrics and accompanied by veils, either in a soft flowing mode or formed into winglike shapes by wire framework underneath.

Footwear was similar for both sexes. Hose might be soled for indoor wear. Outdoors shoes could be worn with wood and cork pattens strapped on to keep the elegant fabrics out of the mud of the streets. Men wore boots for traveling. Long toes were fashionable in the late 14th century, the ends being padded to keep the shape.

The Middle Ages was not a time for heavy use of cosmetics or perfumes, although knowledge of the making of perfume had been earlier introduced into Venice from the East.

EUROPE, 1500–1800

The 16th century witnessed important changes occurring in Europe. The limitations bounding medieval society were gradually being breached; the concepts of the Renaissance were being accepted farther west, in France, Flanders, and, finally, England and Spain. People expected a higher standard of living, and there was an expanding middle class. Europe was also looking outward. From Portugal, Spain, and Italy especially, sailors were voyaging to explore both east and west. Their journeys brought the acquisition of riches, new materials, and precious metals. Costume, as always, reflected all this.

The chief centres of wealth were the pacesetters in fashion. Until about 1510 the style was generated from Italy. After this the Germans and Flemish set the pattern, but from about mid-century it was Spain that dominated the scene.

Styles of the first two decades were a development and expansion of the Italian modes of the late 15th century. Young men wore white silk shirts, frilled and embroidered at the neck and wrists. Over this they wore an abbreviated tunic and close-fitting hose, which were often striped to delineate the masculine limbs. Older men covered the tunic and hose with a long gown, open down the centre front, the edges turned back to display the contrasting lining. Men's hairstyles were long and flowing. Their hats, which were set at a jaunty angle, were made of black velvet and decorated with brooches and plumes. Ladies' gowns had square necklines and were cut low enough to reveal the frilled chemise worn underneath. Sleeves were wide and full, and skirts were held or pinned up to display the undergown.

Slashing

From about 1520 to 1545 the fashionable shape was governed by the strange mode for padded puffs decoratively slashed. This idea is thought to have been derived from the dress of Swiss and Bavarian mercenaries. Each garment was slashed to show the contrasting colour of the material of the one beneath. Whereas the humanist concept of the Renaissance had led to figure display and elegance, the new modes were influenced by the Reformation of northern Europe, giving rise to darker colours, heavier materials, and bulky garments padded to conceal the figure.

The masculine tunic—now called a doublet—had a knee-length, gored skirt, which was open in front to display the now padded protruberant codpiece. Over this was worn a rich velvet gown with fur collar and padded sleeves. Shoes and boots had broad toes and, like all other garments, were decoratively slashed. Short hair styles, small beards, and flat velvet caps worn at an angle were fashionable.

The feminine figure was artificially controlled, not by heavy padding but by a tight underbodice with metal or whalebone strips in the seams to give a small waist

The Bridgeman Art Library/National Museums and Galleries on Merseyside (Walker Art Gallery, Liverpool)

Figure 19: Men's dress of the 16th century, featuring slashed and bejeweled doublet with knee-length, gored skirt; codpiece; fur-trimmed, velvet gown; broad-toed shoes; and flat velvet cap. "Henry VIII," oil on panel by the studio of Hans Holbein the Younger, after 1537. In the Walker Art Gallery, Liverpool.

and slender torso. In contrast, the skirt was shaped by a hooped petticoat made from canvas inset at intervals with circular hoops of wicker to give a cone-shaped silhouette. This fashion had originated during the previous century in Castile, Spain, and by 1500 it had become high fashion there. The Spanish skirt, called a *verdugado,* was bell-shaped, however. About 1530 the cone-shaped hoop was introduced into France, where it was popularized by the queen and called a *vertugade.* The style soon appeared in England, where it was known as a farthingale.

The fashionable lady's headdress was a hood made of dark velvet, with long flaps or folds hanging down the back and sides. The face was framed in front by a jeweled metal frame shaped like a pyramid (the English hood) or a horseshoe (the French hood). Under this was worn a decorative cap which almost concealed the hair.

The costume worn from mid-century until about 1620 was the richest ever seen in the history of European dress. It was made from beautiful fabrics heavily encrusted with embroidery, pearls, and jewels. Fine lawns and lace were employed, and all garments were extensively patterned. During these years Spain was extensively wealthy from the results of the New World exploration, and Spanish dress—which was elegant and tasteful, formal and restrictive, and doubtlessly uncomfortable to wear—was paramount. Paradoxically, when other nations adopted Spanish modes they mostly took them to excess, the Spaniards themselves remaining restrained in their dignified black garments.

The masculine doublet was fitted to the waist and buttoned centre front. Its skirt had now been replaced by trunk hose, which were loose mid-thigh-length breeches gathered into a tight waist and thigh bands; decoration was by embroidered strips called panes. Embroidered clocks decorated the now knitted silk stockings. Shoes had returned to the natural foot form. The dashing Spanish cape had replaced the cumbersome gown. These capes displayed great variety in size, shape, and method of wearing.

Ladies' fashions became more constricted and elaborate as time passed. The boned bodice evolved into a restrictive corset. The farthingale became wider and, by the 1580s, was extended by a padded sausage known as a bum roll or barrel, which was tied around the waist under the skirt. Later the French introduced the wheel farthingale, which was drum-shaped with radiating spokes on top. The gown neckline became very décolleté, almost displaying the breasts. From the 1570s to the 1770s a stomacher—a stiff, V- or U-shaped panel heavily decorated with jewels and embroidery—was often worn over the centre front bodice of the gown.

A characteristic feature of dress of this time for both sexes was the ruff, introduced from Spain. Called a band (ruffs laundered and ready to wear were kept in band boxes), it was a strip of material tied around the neck. Another, ruched strip was sewn on to it. After 1565, with the introduction of starch, ruffs became larger and were often edged with embroidery and lace. The very large "cartwheel" ruffs were not worn in Spain, nor was the wheel farthingale. It was in Holland, Germany, France, and England that the extremes of these fashions, which lasted until about 1620, were seen. The ruff

The Dutch led the fashion world between about 1620 and 1645, setting the mode for a freer, more comfortable attire. With whalebone constriction and distortion by padding removed, the emphasis was once more upon the natural lines of the human figure. By the 1620s Holland was emerging from Spanish control, extending its trade dramatically to become wealthy and influential. The garments worn by the well-to-do were still made from beautiful fabrics, but these now included fine wools as well as velvets and silks. The encrustation of jeweled embroideries was abandoned in favour of a decoration reserved for only certain parts of the costume, permitting the beauty of the fabrics to be appreciated. The material that above all was characteristic of these years was lace, seen especially in the falling bands—large collars covering the shoulders, which had replaced the 16th-century ruffs—and their elegant matching cuffs.

The years 1630–50 have been aptly dubbed by some costume historians as the time of "long locks, lace, and leather." Men grew their hair long and wore it, beautifully cared for, falling naturally onto the shoulders and down the back. Complementary to this coiffure was a large beaver, felt, or velvet hat, dramatically ornamented by coloured ostrich plumes. The leather refers to the fact that the fashionable footwear was a boot rather than a shoe. These boots were made of soft leather; they had heels with platform soles and immense bucket tops, over the edge of which frothed lace-edged boot hose. The doublet had become an elegant hip-length jacket, and the trunk hose were replaced by knee-length breeches tied with a ribbon sash at the knee. Ladies' gowns were simple and stylish; the full skirt fell naturally from a high waistline

and the shoulders were covered, as were the men's by a lace falling band. The hair was dressed high on the crown in a bun decorated with pearl ropes and with ringlets at the sides and brow.

French dominance of European fashion

The *grand règne* of Louis XIV of France lasted from 1643 to 1715. In this time the king established France as a great European power, and from about 1660 France became the unchallenged leader of the European mode, a position it held until almost 1939. The fashions were set in Paris, and knowledge of these styles were disseminated by the mannequin dolls sent out to European capitals and by the costume plates drawn by notable artists from Albrecht Dürer to Wenzel Hollar.

In men's dress the mid-century years represented a transitional period when ribbon and lace ornamentation dominated the whole attire, which consisted of a white shirt, an open, waist-length jacket, and full breeches that resembled a skirt. These breeches were known as petticoat breeches (owing to the effeminacy of their appearance) or, more correctly, as rhinegraves.

Figure 22: *French dress of the Louis XIV period.*
Male attire of long coat with wide, turned-back sleeves, waistcoat, lace cravat, tight-fitting breeches, and periwig. "Louis XIV and His Family," oil painting by Nicolas de Largillière, 1711. In the Wallace Collection, London.

Between 1665 and 1670 came a quite different masculine style and one that presaged the traditional three-piece suit of modern times. Initiated in France, this began as a knee-length coat called a justaucorps, the idea deriving from the Persian caftan. It had no collar and was worn open in front. The short sleeves ended in cuffs. By 1680 the sleeves were longer, and under the coat was worn a slightly shorter waistcoat together with close-fitting knee-breeches. At the neck the falling band had been succeeded by an elegant, lace-edged cravat.

Ladies' styles changed less noticeably at this time. The gown neckline was lowered, and the falling band was replaced by a decorative neckband. The waistline was also lowered, and a stiffened bodice was reintroduced to slenderize it. Skirts were fuller and longer but were draped up on each side and fastened with ribbon bows to display the petticoat underneath.

The periwig

In the last decade of the century both sexes wore a high coiffure. In the case of the men it was a wig. The periwig had been fashionable since about 1670. It was made of naturally coloured hair—human where possible—and consisted of a great curtain of curls and ringlets cascading over shoulders and back, while above the brow the curls rose high on either side of the centre parting. With these full-bottomed wigs the hat, now a three-cornered tricorne, was usually carried under the arm. Ladies wore a tall headdress—the fontange—consisting of tiers of wired lace decorated by ribbons and lappets.

Until the early 1770s, French control of fashion was complete. It was in France where the trades and professions vital to fashion were established: dressmaking, tailoring, wig making, haberdashery, millinery. Textiles for these crafts were varied and luxurious. They were beautiful but, unlike their 16th-century counterparts, were painted, embroidered, or printed with dainty rather than large-motif designs and were decorated not with jewels but with lace ruffles, ruching, and ribbon bows. Silks, satins, taffetas, and velvets were preferred until the last three decades of the 18th century when—as a consequence of the infamous "triangular trade" of manufactured goods, slaves, and raw cotton carried on by Europeans, Africans, and Americans—fine cottons became readily available.

Fundamental changes were taking place in society during the 18th century. Man, for hundreds of years the peacock of fashion, now gradually ceded his position; his garments became less ostentatious while women's dress became the vehicle for change and display. This development was partly the result of the increasing importance of women in society. The middle classes were also increasing in numbers and influence at this time, leading to a wave of egalitarianism in dress and a gradual end to the idea that richness and high fashion were the prerogative of the aristocracy.

During the 18th century men continued to dress elegantly, and changes in their costume style were gradual and limited. The *habit à la française,* the French term for the suit consisting of coat, waistcoat, and knee breeches, had become accepted wear. There was a trend away from brightly coloured satins and velvets, however, toward darker, more sombre cloth materials. The cut of the *habit* also became subdued; there was less decoration, and the style fitted the figure more closely. Wigs were worn through the 1780s, in many and varied styles, but became smaller and less elaborate as time passed; powder was used for much of this time. The tricorne hat remained the style of this century.

For ladies there was a return, by 1700, to a rigid corset to slenderize the waist and a framework petticoat to define the shape of the skirt. In the early decades this was a hoop skirt, circular in section and very full. A popular style of gown worn over this was the sack (*sacque*), which had been derived from the informal house dress of the early years of the century. In France this style was often called the *robe volante.* From a low, wide neckline the gown flared out freely over the hoop petticoat. By 1720–25 the

fullness was concentrated at the back in two deep box pleats sewn to the neckband, while the gown was waisted at the front. This was the *robe à la française.*

The panier

Toward mid-century the hoop framework gradually changed shape to become oval. Then known as a panier (French term for basket), it consisted of a basket form on each hip tied in at the waist by tapes. Soon the frame became so wide that women found it difficult to negotiate a doorway or a sedan chair, so a collapsible folding panier was devised, made only of whalebone hoops connected together by tapes. The years 1750–75 saw the most elaborate and outrageously decorated panier gowns, a riot of ruffles and flounces and ribbon bows. It was also the time of ridiculously high, overdecorated, and powdered wigs. Cosmetics of all forms, many containing white lead, mercury, and other injurious chemicals, were copiously used, a reintroduction of the 16th-century practice.

The Bettmann Archive

Figure 24: French woman wearing lavishly decorated panier gown and elaborate, powdered hairstyle. "The Queen's Lady-in-Waiting," engraving by Jean-Michel Moreau le Jeune, 1776.

By the 1770s a reaction to this excess was setting in in England, where simpler gowns with a framework petticoat were worn, and the fullness of the skirt was drawn to the back. A sash encircled a high waistline, and a soft fichu was draped around the neck. These gentler yet elegantly feminine styles gradually spread throughout Europe and were finally accepted in France.

Children's clothing

For centuries children had been dressed as miniature adults, but in the 1770s there was a marked divergence from this established custom. Children began to be dressed in more comfortable garments suited to their age. Girls' dresses were rather like the easier styles of their mothers at this time, but boys were dressed in a frilled shirt and ankle-length trousers, the waistband of which was buttoned to the shirt. This costume, in which the wearing of trousers as fashionable dress antedated its introduction for adults by a generation, was oddly entitled a skeleton suit.

(D.Y.)

COLONIAL AMERICA

Seventeenth-century North America was colonized by settlers from northern and western Europe. These settlers brought with them habits and ideas in dress that were characteristic of their places of origin, but their clothes were also influenced by the climate of the part of the country to which they had come. For example, the earliest settlers, the Spanish, arrived in Florida in 1565. There, as well as in their later settlements in Texas and California, the climate was not very different from that of Spain, so that the colonists could continue wearing Spanish styles. In contrast, colonists farther north in New England experienced harsher winters than they had been accustomed to and so found a greater need than they had in England to wear furs and skins.

In all areas many colonists thought it important to preserve class distinctions. Because of this, they passed many sumptuary laws to maintain differentials. Such protocol in dress was a visible expression of their determination to maintain their heritage. Similar laws restricting dress were also passed for religious reasons, reflecting the mid-century Civil Wars in England. In America, as in England, plain dress and rich dress became, in effect, the respective symbols of Puritan and Cavalier. Many Virginia colonists leaned toward the Cavalier; Puritan ideas prevailed in Massachusetts. Virginia dress, though it differed little in design from that of New England, was in general more costly. The Puritans omitted such extravagances as fine brocades, rich laces, ribbons, and feathers; the change to simpler dress that had begun before their departure for America continued.

Difference between American and European clothing

Probably the greatest change in clothing in America, as opposed to Europe, took place in everyday working costume, the Americans wearing heavier and warmer clothing made of stronger and stouter materials. The distinguishing characteristic of all clothes listed in the inventories of the colonization companies is their wearing quality, and the terms "heavy cloth" and "strong durable stuff" are often encountered. Men and boys wore comfortable, durable jackets and breeches, for example, made from deerskin and buckskin tanned to the consistency of fine chamois with the use of animal brains, a process the colonists had learned from the Indians.

For many English colonists the early years were hard. Most people made their own clothes, cultivating flax and cotton and raising sheep for wool. Clothes for everyday wear were plainer versions of those worn back in England. Best clothes were kept for Sundays and holidays; such garments lasted a long time, and most colonists were therefore wearing styles considered old-fashioned in England. For example, men wore breeches full at the waist, a doublet and jerkin, and a hip-length, loose overgarment that had been fashionable in Europe in the later 16th century. This was the mandilion, derived from the medieval tabard. It was now a loose jacket with free-hanging sleeves. It had been adopted by the Puritans, who took it to New England. The colonist version was generally lined with cotton and fastened with hooks and eyes. By mid-century

Figure 25: A woman and child in stylish 17th-century American Colonial dress. Both dresses are made of fine fabrics and have virago sleeves. The child wears a simple linen falling band collar, while the mother wears a more elaborate lace version. "Mrs. Elizabeth Freake and Baby Mary," oil on canvas by an unknown artist, *c.* 1671–74. Worcester Art Museum, Worcester, Mass

the buff coat had also become a staple garment among colonists in this area. Originally a military coat made of hide, it was durable and warm; it was cut simply in four sections, with or without sleeves.

The everyday dress of women was a short gown of durable material, with a full skirt over a homespun petticoat, covered by a long apron of white linen. The more stylish dress was longer and made of finer material. It often had the virago sleeve—full at elbow and shoulder and drawn in at intervals by strings of narrow ribbon—that appears in most 17th-century portraits of American women and children.

Slashed clothing was fashionable, as in Europe; in the openings made by the slashes could be seen rich materials. In 1634, however, the general court of Massachusetts forbade men and women to make or buy clothes with more than one slash in each sleeve and another in the back. The starched ruff of the early 17th century gave way to the falling band, the common form of which was a broad, plain, linen collar. Both men and women wore this collar and plain linen turnback cuffs.

Stockings were either knitted or cut from woven cloth and sewn to fit the leg. They were attached to men's breeches by points, or strings, which were also used to secure other garments; later, sashlike garters replaced points. Both men and women wore stout leather shoes with medium heels. Men also wore French falls, a buff leather boot with a high top wide enough to be crushed down. After 1660 the jackboot, a shiny black leather boot large enough to pull over shoe or slipper, replaced the French falls; oxfords of black leather were worn by schoolchildren.

Headgear

Both men and women wore a steeple hat of felt or the more expensive beaver. Men also wore the montero cap, which had a flap that could be turned down, and the Monmouth cap, a kind of stocking cap. Women of all ages wore a French hood, especially in winter, when it was made of heavy cloth or fur-lined; this hood, tied loosely under the chin, is seen in many portraits of the time. Sometimes the steeple hat was worn on top of the hood.

Dutch settlements, including New Netherland and New Amsterdam (later New York), were founded in the 1620s. The settlers in these areas were industrious and tolerant, mixing harmoniously with colonists from other nations. They created a wealthy community but placed no restrictions on dress for sumptuary or religious reasons. Their attire was, as it had been in Holland, of high quality and fashionable but not ostentatious.

French colonists, like the Dutch, were assisted by their home government with provisions and equipment to found a settlement, this time on the lower reaches of the Mississippi River. They established the city of New Orleans in 1718 and called the area Louisiana, after Louis XIV. Early settlers there made their own fabrics and clothes but also bartered with the Indians for skins.

By 1700 Americans were dressing fashionably, and the distinctions between colonists of one nation and another were no longer very noticeable. Americans who were well-to-do followed the current fashions from Europe, and the main differences were between city dwellers and those from rural areas. Many of the latter still made their own clothes from homespun and woven fabrics, but the former could afford to import luxury fabrics and follow the fashion trends. Fashion dolls and costume plates now reached America, and it was possible to be au courant with the latest modes. Even during the years 1750–70, when luxurious styles prevailed in Europe, the Americans followed every frivolous idiosyncrasy.

In the first half of the 18th century, English colonists tended to follow English fashions, but the American Revolution altered this attitude. During the war there were severe restrictions on imported goods, and, when the war was over and independence had been won, most Americans did not return to buying their clothes from England; they went directly to the source of fashion—Paris.

(A.W.M./D.Y.)

THE OTTOMAN EMPIRE

From the early 12th century the Byzantine Empire had begun its slow decline in the face of the Turkish advance. In 1324 or 1326 the Ottoman Turks captured Bursa, on the opposite side of the Sea of Marmara from Constantinople, and this city became the first capital of the young empire. In 1453 Constantinople itself fell to the Turks. By then the costume of both cultures had been influencing one another for many years. From the Turks had come the wearing of the caftan and trousers; the Byzantines contributed beautiful silks, jeweled embroideries, and cloth of gold. The Turks adopted this richness of attire with such enthusiasm that, by the 16th century, sultans were trying to stem the tide of luxury in dress, as western Europe had long been attempting to do, by the passing of sumptuary laws forbidding the wearing of these materials and decoration except by the privileged few.

From the 15th century until the modernization of Turkey soon after 1918, the basic garments of the general population changed comparatively little. Although a Europeanization movement had begun about the middle of the 19th century, this was a slow process, affecting mainly the dress of the upper strata of society and that of the urban population. For many years such attire was a blend of styles from western Europe worn together with traditional Ottoman garments.

Traditional Ottoman dress

Traditional men's dress comprised a shirt, trousers, jacket, and boots. The trousers were of the very full, baggy type (similar to the Middle Eastern *chalvar*), fitting tightly only on the lower leg. A deep waist sash, the *kuşak,* bound the body over the junction between trouser and shirt. The jacket was a short one, worn open, and was decoratively embroidered. In cold weather a caftan would be worn on top of these garments. The only difference between the clothing worn by the average member of the population and those in a higher social class was that the garments of the latter would be made from richer, more decorative fabrics and that a long caftan would be worn on top. Sometimes more than one such coat was worn, with or without sleeves.

The traditional Turkish cap, the tarboosh, resembles an inverted flower pot and is made of cloth or felt. Similar to the fez, a term believed to have derived from the Moroccan town of that name, this cap was for centuries under the Ottoman Empire bound around the brow with a turban. The cap was made part of the national dress of the Turks during the 19th century and remained so until it was proscribed when Turkey became a republic in 1923. It is still worn by Muslims of both sexes in the Middle East.

The dress for women in the Ottoman Empire was very similar to that worn by Muslim women in the Middle East. It consisted of a knee-length, white, sleeved chemise (*gömlek*) and long drawers tied at the waist (*dislik*). The usual full trousers (*chalvar*) were accompanied, as in men's dress, by a decorative waist sash (*kuşak*). Over these garments a waistcoat (*yelek*) and long gown (*anteri*) were worn. Backless slippers were worn indoors. Outdoors the enveloping cloak (*tcharchaf*) and veil (*yashmak*) were obligatory, and decorative pattens (*kub-kobs*) kept the elegant slippers out of the mud of the streets.

The Ottoman Empire extended its control westward in Europe over the Balkans and as far as Hungary, where masculine dress was strongly influenced by Turkish styles. Until well into the 18th century men in these non-Muslim areas wore the dolman over the *mente* (both styles of caftan), together with trousers, boots, and a fur-trimmed hat known as the *kucsma*. Dress for women in these areas, however, followed the current styles of western Europe.

EUROPE AND AMERICA: 19TH AND 20TH CENTURIES

The 19th century. The influence of national features in dress had been declining since about 1675 and by 1800 had become negligible; from then on fashionable dress design was international. The character of the feminine wardrobe stemmed from Paris, the masculine from London. The English gentleman was established as the best-dressed, best-mannered in Europe, the lead being set by elegants such as Beau Brummell, whose clothes were copied by the prince regent himself (later King George IV). Brummell was so concerned with fit that he had his coat made by one tailor, his waistcoat by another, and his breeches by a third. The neckcloth was so elaborate and voluminous that Brummell's valet sometimes spent a whole morning getting it to sit properly.

Dominance of British menswear

It was during this period (*c.* 1811–20) that English modes for men became everywhere accepted as correct, even in Napoleonic France (the top hat, for example, became almost universal), and men's dress slowly became stereotyped, etiquette having laid down detailed regulations for the attire to be worn for different occasions, for different times of day, and by the various social classes. The tailcoat, waisted and padded on the chest, was de rigueur, accompanied by a waistcoat and now by close-fitting trousers called pantaloons, which were first buckled at the ankle and later, after 1820, strapped under the instep.

French dominance of what was chic for women was absolute during the 19th century. Parisian designs of garments and accessories were publicized throughout Europe and America by fashion plates and journals. At first originating from England and France, after 1850 they came from all European countries, and the Americans introduced some of the later world-famous journals—for example, *Vogue* and *Harper's Bazaar*.

Until about 1820 women's dress continued to reflect styles initiated as a result of the French Revolution. These fashions, which attempted to translate such ideals of the Revolution as democracy and liberation, were supposedly based upon the classical dress of ancient Greece. Ladies wore loose, draped, high-waisted gowns in white or pale colours in imitation of those depicted by white marble statuary. Corsets were abandoned; indeed, women wore a minimum of thin garments with little underwear—a totally unsuitable garb for the winters of northern Europe. To attempt to offset the chill, women adopted a three-quarter-length overdress made from a warmer, richer-coloured material and a variety of stoles, shawls, and pelisses. Hair was dressed classical fashion in a chignon bound with ribbons and decorated with plumes. The Romantic age of the 1830s brought back more colour, a tighter waistline at a more natural level, fuller, shorter skirts, leg-of-mutton sleeves, and complex high coiffures surmounted by large-brimmed hats or bonnets.

From the 1840s men's dress began to be more casual but lost most of its colour: black, shades of gray, and white were the norm. The formal black tailcoat was now reserved for evening attire. For daywear, tailcoats of various types were worn with a waistcoat and the new looser style of trousers over boots. Neckwear was plainer, consisting of a collar with neck scarf. The three-piece lounge suit, with a jacket instead of a tailcoat, was introduced in the 1850s for informal occasions. In the last two decades of the century a more countrified attire consisting of Norfolk jacket and knickerbockers became popular. (The name knickerbocker was taken from the nom de plume—

Diedrich Knickerbocker—adopted by Washington Irving for the comic history of New York that he wrote in 1809. The Knickerbockers, a family of Dutch settlers in 17th-century New Amsterdam, were depicted in George Cruikshank's book illustrations wearing the full breeches of this time.)

The greater informality extended to hat design, with new styles being introduced that were gradually adopted for less informal use. The bowler, also known by such other names as the colloquial British "billycock" and, in America, the derby, was introduced about 1850 by the hatter William Bowler. The straw boater, originally meant to be worn on the river, became popular for all summer activities. The homburg felt hat, introduced in the 1870s and popularized by the Prince of Wales (later King Edward VII), stemmed from the German town of that name. Also popular at this time for sports and country wear in Britain was the deerstalker cap immortalized in Sir Arthur Conan Doyle's Sherlock Holmes stories.

Between about 1840 and 1870, long, bushy side-whiskers were fashionable. These whiskers, which left the chin clean-shaven, were called Piccadilly weepers in England; in America they were commonly referred to as burnsides or sideburns, after the U.S. Civil War general Ambrose Burnside, or as dundrearies, after a character in a contemporary play. Other popular beard styles included the imperial, a small goatee named for Napoleon III, and the side-whiskers and drooping mustache known as the Franz Joseph in honour of the head of the Austro-Hungarian Empire. After 1880 men tended to be clean-shaven or to wear a mustache only.

The second half of the 19th century was a time of prosperity in Europe. Despite wars and upheavals, the upper classes dressed fashionably and luxuriously. The styles of men and women acted as foil to one another—the men's dress sombre, dignified, and only slowly changing, that of the ladies changing ever faster in a kaleidoscope of modes. The technical advances and the capability for mass manufacturing brought about by the Industrial Revolution were making fashionable dress available to a rapidly expanding middle class. The invention of the sewing machine and the jacquard loom for weaving patterned textiles, the development of the ready-to-wear trade, the growth of new marketing techniques, and the establishment of department stores were revolutionizing the fashion scene.

Haute couture

In France haute couture had taken over control of the fashion-design world. The Englishman Charles Frederick Worth, who had emigrated to Paris in 1845, was the first of the great couturiers and one of the most influential. He introduced the practice of preparing a collection of designs, and he was the first to use live mannequins to display designs to buyers. Although only the rich could afford designer fashions, the styles gradually reached the ready-to-wear market (in a modified form that nonetheless prompted the introduction of new fashions for the upper classes), so that haute couture came to dictate women's fashions.

Women's dress from 1840 onward was, once more, dominated by a restrictive boned corset and framework underskirt. The fullness of the skirt was at first achieved by adding more layers of petticoats, leading to the crinoline petticoat of 1850. Named after the materials from which it was originally made (Latin: *crinis,* "[horse] hair"; *linum,* "thread"), this petticoat was, like its predecessors the farthingale and the hoop, a heavy underskirt reinforced by circular hoops of whalebone. By 1856 the weight of the crinoline and the petticoats became intolerable, and the cage crinoline was invented. This was a flexible steel framework joined by tapes and having no covering fabric. Sold at two shillings and sixpence, it was immensely popular and worn by most classes of society, at least for Sunday dress. It became the target for cartoonists, who took full advantage of all possible ludicrous situations; but this in no way lessened its popularity.

Gradually, in the 1860s, the shape of the crinoline changed, metamorphosing into that of the rear bustle, which was fashionable in the 1870s and '80s. Only in the 1890s did the skirt return to a relatively slender silhouette, but there was no letup in the constrictive corset, which was then at its most painful and harmful stage. In general, the styles of the late 19th century were feminine and elegant but not easy to wear. They restricted natural movement with their multiple layers, overdecoration, and sheer quantity of material.

Women's hair, always worn long during the century, was, from about 1840 to 1870, dressed in a severe style in which it was drawn back tightly from a centre parting into a bun at the back. Later styles were more feminine, dressed high on top and in a chignon or ringlets behind. The bonnet in many and varied guises was the chief head covering and was replaced by dainty hats only in the 1870s and '80s. Throughout the 19th century cosmetics were disapproved of; this was a strong reaction to the excessive use in the previous century.

Not all the women of the 1880s, however, wore these fashionable clothes. Followers of the Aesthetic movement in England wore looser garments—though the waists were still tight—with enormous sleeves supposed to resemble those worn by women in early Florentine paintings. The humorous journals of the period made great play with the contrast between fashionable and Aesthetic modes.

"Bloomers"

An earlier attempt to introduce a more comfortable, practical attire for women had been made by the American Elizabeth Smith Miller. The costume she designed was enthusiastically advocated by her friend Amelia Jenks Bloomer, a journalist and writer. In 1851 Bloomer traveled to London and Dublin to publicize this dress reform. The outfit, consisting of a jacket and knee-length skirt worn over Turkish-style trousers, was regarded as immodest and unfeminine. It was greeted with horror and disdain, and the idea quickly died. What has survived is the name "bloomers," which originally referred to Miller's full trousers but was later applied to long knickers worn as underwear in the early 20th century. Miller's garment was also the inspiration for "rationals" (sometimes also known as bloomers), the knickerbockers worn by women for cycling and sport in the 1890s.

Children's clothes were less sensible and comfortable than they had been 50 to 60 years before. What had started in the 1820s as rational dress for boys had been formalized into the rigid discomfort of the Eton suit with its stiff white collar. Fortunate boys were dressed in sailor suits, and unfortunate ones as "Little Lord Fauntleroy," in velvet suits with lace collars and cuffs and with the hair dressed long in curls. Little girls were dressed in elaborate and easily soiled garments with much lace. Their skirts were shorter than those of adult women, but the waists were nearly as tight. (Ja.L./D.Y.)

The early 20th century. There were no fundamental changes in dress during the first decade of the 20th century. Men continued to wear a black frock coat with gray striped trousers for formal day wear and a black tailcoat and trousers with a white waistcoat for evening wear if ladies were present, although in America the tuxedo, or dinner, jacket was beginning to provide a more comfortable alternative. (The term derives from the fact that the style was introduced in the millionaire district of Tuxedo Park in the state of New York for wear at small dinner parties.) Three-piece lounge suits were worn for less formal day functions, and for country and sportswear the Norfolk jacket and knickerbockers remained popular.

For ladies the ideal figure was an unusual one, comprising a full, forward-thrusting bosom, tiny waist, and generous, backward-slanting hips. This unnatural S-bend posture was achieved mainly by a boned corset that was long and rigid in front and shorter at the rear. The costume was extremely feminine, overdecorated with flounces and lace, frills and embroidery. It was totally impractical but ornamental and attractive. Picture hats were set upon pompadour coiffures, affixed with vicious-looking hatpins. The high neckline was boned at the sides up to the ears, and the skirt hem trailed on the ground, its beautiful fabric protected from the dirt by ruffled petticoat "sweepers."

From 1910 important changes began to take place in feminine attire. The French couturier Paul Poiret led the field in designing an exotic range of glamorous creations made from superb fabrics in brilliant colours. Poiret, who was designing for the "new woman," freed women from the multiplicity of petticoats and from the excruciating corset. His gowns still reached the ground, however, and the skirts were restrictive, making it difficult to walk. His hobble skirt, in which the material was very narrow at the ankle, was particularly aptly named; in some cases a deep band encircled the skirt at ankle level, rendering it difficult to put one foot in front of the other. Poiret's other designs included the lampshade, or hoop tunic, skirt. He also took many of his more exotic designs from Oriental prototypes; these included turbans, Eastern-style trousers, and harem skirts.

Influence of social changes on dress

Women were beginning to question their status in a man's world. Some became suffragettes, some went to work outside the home. A more practical form of dress became popular, with the blouse and skirt replacing the ruffled tea gown. During the war years of 1914–18 these changes accelerated. A minority of women were in uniform, but far more worked in factories, in offices, as postal carriers and in other jobs previously performed by men. To meet their needs, the picture hat was replaced by a small neat design, and the skirt hemline rose to eight inches above the ground, revealing the ankles for the first time.

The postwar 1920s brought a complete change to the fashion scene. Men's dress moved more slowly than women's, but even here far more variety appeared in colour schemes and fabrics, and the trend toward informality was accelerated. The tailcoat was reserved for weddings and dances, the lounge suit became the accepted city wear, and sports jackets and gray flannels were popular for casual attire. After 1925 trousers commonly featured turnups (cuffs in America), and the legs became increasingly wider; the popular "Oxford bags" measured 20 inches at the hem. Knickerbockers had become fuller and longer, overhanging the kneeband by four inches, and were thus known as plus fours, which remained fashionable until at least 1939. Knitted pullovers (often homemade) in coloured (fair isle) patterns replaced the waistcoat for informal occasions. Technical advances had improved water-repellent fabrics, and most men had a raincoat. A favourite style

Figure 30: "Afternoon Dress with Hoop Tunic," by Bernard Boutet de Monvel, 1914. In the collection of François Boucher, Paris.

was the trench coat, a classic design based upon the coats worn by World War I officers in the trenches. Men were mostly clean-shaven, and their hair was short. A peaked cap accompanied leisure wear, and a trilby felt hat the lounge suit. (The latter was named after George du Maurier's novel; the American term was fedora, named for the heroine of a play.)

For women in the 1920s, freedom in dress reflected the new freedoms opening up for them to take up careers, to study at college, to enter professions. Only a small percentage of women took up such opportunities, far fewer than today, but the revolutionary changes nonetheless affected the type of clothes worn by most women in the Western world. The skirt hemline rose steadily to become, at its shortest in the years 1925–27, knee-length. With the short skirts, flesh-coloured stockings were introduced, made from expensive silk or more practical lisle or wool (other colours were also worn). Corsets, layers of petticoats, and overdecoration all disappeared to be replaced by a boyish figure style in which the waist, breasts, and hips were all understressed. Probably the most revolutionary change was in the coiffure. Hair was first cut shorter during the war years to make it easier to care for, and by the 1920s the shingle and the more severe Eton crop were being adopted by the ultrafashionable. Marcel waving, introduced in the late 19th century, and the later "perm" also contributed to manageability and became popular at this time. Permanent waving abolished forever the nightly chore of setting curl papers and pins. The new, sleek hairstyles were accompanied (and virtually concealed) by the generally unflattering cloche hat, which closely covered the head down to the eyes: only a beautiful woman could wear one with chic.

Women's hairstyles

Femininity returned in the 1930s. The ideal figure was still slim, but the low-waisted, tubular look was out of style. The uplift bra enhanced the breasts, and the waistline returned to its natural level. The skirt lengthened again until it reached about eight inches above the ground for the daytime and ground length for the evening. For evening styles, the backless dress and halter neckline became fashionable. The bias cut of material, a mode introduced in the 1920s by the French couturiere Madeleine Vionnet, was widely adopted in the 1930s and was very effective with the longer skirts, creating a figure-hugging style which then flared out at the hemline.

By this time there was available a great variety of specialized clothing for different occasions, including for sport and leisure or resort activities, such as swimming, walking, and cycling, as well as for parties and dances. The cosmetics industry, led by the United States, had also expanded and became big business in the 1930s; most women routinely carried face powder, lipstick, eye shadow, and tweezers in their handbags for running repairs.

The high proportion of men and women in uniform in the years 1939–45 strongly influenced the civilian dress style. For women, garments had square padded shoulder lines, and skirts were a practical knee length. Trousers were widely worn by both civilian and military women. After World War II, trousers and trouser suits remained popular, especially between 1945 and 1970. In Europe, the war years meant austerity and clothing coupons; fashion did not have a high priority. Shortages of materials both during and immediately after the war led to the introduction of "utility" styles, especially in Britain, where gov-

ernment rulings insisted on the removal of all superfluous trimmings, including pockets and pleats, and restricted the fullness of garments in order to economize on the amount of fabric used.

Post-World War II. It is extremely difficult to sum up the changes in dress that have taken place since 1945. Fashions have changed at a far greater pace than ever before, a pace that is still accelerating. The rules of etiquette governing what type of dress should be worn by whom and when have virtually disappeared. It has become the accepted dictum to "do your own thing," to choose clothes, whether for day or evening, formal or holiday wear, according to personal inclination. Wide-scale advertising, especially on television, and the modern marketing system have brought fashion within the reach of all, both in cost and availability. Leading manufacturers and department stores purchase original designs from fashion houses and then manufacture ready-to-wear versions in quantity at various price levels to suit the entire population.

One of the most influential factors in the development of modern fashions has been the technological advance in the production of synthetic textile fibres. Permanent pleating, fast dyes, crease resistance, preshrinking, and other easy-care characteristics of synthetics have made it possible to manufacture clothing more quickly and less expensively. Although traditional natural fabrics remain popular, they have been almost completely replaced by synthetics in the manufacture of some garments. Women's stockings made of nylon, for example, first went on sale about 1940 and, after World War II, soon supplanted all other types. Similarly, the underwear industry was revolutionized when latex thread was employed, along with the zipper, to fabricate comfortable two-way stretch suspender belts, effectively banishing the hated corset.

The keynote of the changes in men's dress has been casualness. The tailored jacket and vest have been steadily ousted and often replaced by knitted pullovers and cardigans. Central heating of homes and transport by car have virtually done away with overcoats, heavy tweed suits, and hats; well-cut shirts and trousers are normal office and car wear. In line and cut, fashion styles have changed more quickly than ever before, with the narrow cuffless trousers, trousers with the waistband at hip level, and the bell-bottomed flared trousers all popular at various times. For elegant evening wear a coloured velvet jacket with cummerbund was long favoured, although many men accepted little distinction between day and evening attire.

Soon after the war the French designer Christian Dior raised feminine morale after years of drabness by introducing his 1947 "Corolle" collection, soon to be dubbed the "New Look" by the American press. Here was a return to femininity: a long, full skirt with a bouffant ruffled petticoat beneath, a slender waist, and sloping shoulders. The look did not last long. Although women liked it, it was not sufficiently practical for the new world of women out at work.

The miniskirt

More popular, so much so that the fashion was slow to die and has since been revived, was the miniskirt, introduced in 1965 by Mary Quant in London and André Courrèges in Paris. Starting at mid-thigh length, the hemline crept upward to become a micro-skirt, a style that had only been made feasible by the introduction of nylon

tights (panty hose in the United States). Other lengths appeared—the midi and the maxi—but neither was as popular as the mini.

A feature of fashion since 1945 had been the emphasis on clothes for the young, something never before experienced. Throughout history children and young people wore basically the same type of clothes as their parents. After 1945 a generation was growing up to enter a world of easy employment opportunities and good wages. The marketers of clothes took full advantage of this and aimed their designs toward the young; a complete teenage wardrobe evolved, comprising garments almost unwearable by older people. Clothes were extremely tight-fitting and casual. Blue jeans became and, indeed, continued to be a uniform for the young. Young men and women began to ape each other's styles, and unisex clothes were born. In the 1960s London's Carnaby Street became an important centre for antiestablishment "mod" fashions. Since then, styles have moved quickly and have been full of contradictions. Ethnic, romantic, nostalgic, erotic, punk, and conservative effects, among others, have all had their adherents.

(D.Y.)

The history of Eastern dress

Western-style clothes, which many people find convenient to wear during business hours, are now a common sight in many large cities of eastern and southern Asia. This is particularly so in Japan, a country which, since 1945, has been especially influenced by the American way of life and has built a reputation as an international fashion centre. However, even here, as in much of Asia, it is not uncommon for a reversion to traditional dress to take place in the home.

Over the centuries, notably in Korea and Japan, these traditional styles of dress have reflected marked Chinese influence, though both countries developed characteristic styles of their own. In like manner, modes of dress in the Indian subcontinent have been a source of inspiration to some of the countries of Southeast Asia and of the East Indian archipelago.

CHINA

More than 2,000 years before the beginning of the Christian era, the Chinese discovered the marvelous properties of silk and shortly thereafter invented looms equipped with devices that enabled them to weave patterned silks rapidly enough to satisfy the demand for them by luxury-loving Chinese society. Thus, centuries before Chinese silks began to be shipped westward and still more centuries before the West learned the secret of sericulture, the people of China had already established ultrarefined standards of elegance in matters of dress.

The earliest period of Chinese history for which reliable visual evidence of clothing styles is obtainable is the Han dynasty (206 BC–AD 220). Han bas-reliefs and scenes painted in colour on tiles and lacquers show men and women dressed in wide-sleeved kimono-style garments which, girdled at the waist, fall in voluminous folds around their feet. The graceful dignity of this *p'ao*-style robe, which continued to be worn in China until the end of the Ming dynasty in 1644, is clearly revealed in Chinese figural paintings attributable to the interval between the 8th and the 17th century (Figure 34). Other traditional garments include the tunic or jacket, worn by both sexes over loosely cut trousers. For colder weather, clothing was padded with cotton or silk or lined with fur.

The *p'ao*

Chinese records indicate that at least as early as the T'ang dynasty (618–907) certain designs, colours, and accessories were used to distinguish the ranks of imperial, noble, and official families; but the earliest visual evidence of these emblematic distinctions in dress is to be found in Ming portraits. In some of these, emperors are portrayed in voluminous dark-coloured *p'ao* on which the 12 imperial symbols, which from time immemorial had been designated as imperial insignia, are displayed. Other Ming portraits show officials clothed in red *p'ao* that have large bird or animal squares (called "mandarin squares," or *p'u-fang*) on the breast, specific bird and animal emblems

Figure 34: The legendary Emperor Yao wearing a *p'ao*-style robe, a wide-sleeved kimono-style garment, which, girdled at the waist, falls in voluminous folds at the feet. Hanging silk scroll by Ma Lin, Southern Sung dynasty (1127–1279). In the National Palace Museum, Taipei, Taiwan.

to designate each of the nine ranks of civil and military officials having been adopted by the Ming in 1391.

When the Manchus overthrew the Ming in 1644 and established the Ch'ing dynasty, it was decreed that new styles of dress should replace the voluminous *p'ao* costume. The most formal of the robes introduced by the Manchus was the *ch'ao-fu,* designed to be worn only at great state sacrifices and at the most important court functions. Men's *ch'ao-fu* (Figure 35) had a kimono-style upper body, with long, close-fitting sleeves that terminated in the "horsehoof" cuff introduced by the Manchus, and a closely fitted neckband over which was worn a detached collar distinguished by winglike tips that extended over the shoulders. Below, attached to a set-in waistband, was a full, pleated or gathered skirt. Precisely stipulated colours and pattern arrangements of five-clawed dragons and clouds, waves, and mountains were specified for the *ch'ao-fu* of emperors, princes, nobles, and officials; the bright yellow of the emperor's robe and the 12 imperial symbols emblazoned on it clearly established his lofty rank. All other ranks wore "stone blue" *ch'ao-fu* decorated in accordance with prescribed rules about the number, type, and arrangement of dragon motifs.

Only women of very high rank were permitted to wear *ch'ao-fu.* Women's robes were less commodious than the men's and were cut in long, straight lines with no break at the waist. The narrow sleeves with horsehoof cuffs of these *ch'ao-fu* robes and the arrangement of their dragon, cloud, mountain, and wave patterns were essentially the same as those of the so-called dragon robes discussed below. They were clearly differentiated from the dragon robes, however, by their capelike collars and by flaring set-on epaulets which, gradually narrowed, were carried down under the arms. Stolelike vests, always worn over women's *ch'ao-fu,* were also a distinguishing feature of this costume.

"Dragon robes"

Chi-fu, or "dragon robes" (*lung-p'ao*) as they were usually called, were designed for regular court wear by men and women of imperial, noble, and official rank. The *chi-fu* was a straight, kimono-sleeved robe with a closely fitted neckband that continued across the breast and down to the underarm closing on the right side, the long tubular sleeves terminating in horsehoof cuffs. The skirt of the *chi-fu* cleared the ground to permit easy walking and in men's garments was slit front and back as well as at the sides to facilitate riding; the extra slits were the only feature that distinguished the *chi-fu* of men below the rank of emperor from those of their wives. All *chi-fu* were elaborately patterned with specified arrangements of dragons, clouds, mountains, and waves, to which were added auspicious or Buddhist or Taoist motifs. Distinctions in rank were indicated by the colours of the robes and by slight variations in the basic patterns; however, because of the large number of personages who wore *chi-fu,* these distinctions were not always easily recognizable. Emperors' *chi-fu,* either yellow or blue, were always distinguished by the 12 imperial symbols.

The informal Manchu *ch'ang-fu,* a plain long robe, was worn by all classes from the emperor down, though Chinese women also continued to wear their Ming-style costumes, which consisted of a three-quarter-length jacket and pleated skirt. Men's *ch'ang-fu,* cut in the style of the *chi-fu,* usually were made of monochrome patterned damask or gauze; women's *ch'ang-fu* had wide, loose sleeves finished off with especially designed sleevebands decorated with gay woven or embroidered patterns.

The declining Ch'ing dynasty was finally swept aside in 1912, and Western influences exerted pressure on China to begin to emulate the world outside its boundaries. Under the new republic the traditional Chinese culture began to give way to modern ideas. Gradually this was reflected in dress. By the 1920s women, in particular, adopted a compromise attire. This was the *ch'i-p'ao,* better known in the West by its Cantonese name, cheongsam. The *ch'i-p'ao* had developed from the *ch'ang-fu,* and by 1930 the majority of women were wearing it. A close-fitting dress made from one piece of material, the *ch'i-p'ao* was fastened up the right front side. It had a high mandarin collar, and its skirt was slit up the sides to the knee. It was made of traditional Chinese fabrics, padded in winter for warmth. At first it was a long dress, but the hemline gradually rose to come into line with Western dress.

In mainland China the communist revolution of 1949 brought strict directives on dress. Styles were to be the same for everyone, whether man or woman, intellectual or manual labourer. This drab uniform was a blend of peasant and military design. It consisted of a military-style high-collared jacket and long trousers. Men's hair was short and covered by a peaked cap. Women's hair was longer but uncurled. Shoes had flat heels. No cosmetics or jewelry was permitted. Traditional Chinese cotton was used to make the garments; colour designated the type of worker. After about 1960 a slow Westernization set in, permitting a variation in colour and fabric. Dresses were introduced for women.

JAPAN

Earliest representations of Japanese dress styles

The earliest representations of dress styles in Japan are to be found in 3rd- to 5th-century-AD clay grave figures (*haniwa*), a few of which show men and women wearing meticulously detailed two-piece costumes consisting of crossed-front jackets that flare out over the hips, the men's worn over full trousers, which, banded above the knees, hang straight and loose beneath; women's jackets were worn over pleated skirts (Figure 36).

Two-piece costumes appear to have been worn regularly during the 7th and 8th centuries, the jackets of this period being called *kinu,* the men's trousers *hakama,* and the women's skirts *mo.* It is known, however, that during the Nara period (710–784) Japanese court circles adopted Chinese court dress, the most characteristic feature of which was the long kimono-style *p'ao* garment; thus, it must be supposed that the *kinu, hakama,* and *mo* were the accoutrements of middle- and lower-class society, though these garments may also have been adapted for wear under the *p'ao.* It is clear that emblematic colours and patterns as well as the *p'ao* style were borrowed from China because modern court dress in Japan, which has been little changed since the 12th century, has many purely Chinese characteristics.

Court costumes

The most important court costumes of Japan are the *sokutai* of the emperor and the *jūni-hitoe* of the empress, which are worn only at coronations and at very important ceremonial functions. (Similar costumes are worn by the crown prince, by princes and princesses of the blood, by

By courtesy of the National Museum, Tokyo

Figure 36: Japanese grave figure, wearing meticulously detailed two-piece costume of flared, crossed-front jacket and pleated skirt. Clay, 3rd to 5th century. In the National Museum, Tokyo.

high officials, and by ladies-in-waiting.) The voluminous outer robe (*ho*) of the emperor's *sokutai* is cut in the style of the Chinese *p'ao* but is given a distinctively Japanese look by being tucked up at the waist so that the skirt ends midway between the knees and the floor. This *ho* robe is yellow (the colour worn only by emperors and their families in China), and it is patterned with *hō-ō* birds and *kilin* (Japanized versions of the mythical Chinese *feng-huang* and *ch'i-lin*). The outer and most important of three kimonos worn under the *ho* is the *shitagasane,* which has an elongated back panel that forms a 12-foot (4-metre) train. The *shitagasane* is made of white damask, as are the baggy white trousers (*ue-no-hakama*) that are a characteristic feature of the *sokutai* costume. Both of these garments and a cap-shaped headdress (*kammuri*) of black lacquered silk, with an upright pennon, decorated with the imperial chrysanthemum crest, are purely Japanese in style, but the ivory tablet (*shaku*) carried by the emperor when wearing the *sokutai* was undoubtedly inspired by tablets of jade that Chinese emperors carried as symbols of their imperial power.

The outermost garment of the empress' *jūni-hitoe* costume is a wide-sleeved jacket (*karaginu*) that reaches only to the waist and has a pattern of *hō-ō* bird medallions brocaded in colours of the empress' choice. Attached to the waist at the back of the *karaginu* is a long, pleated train (*mo*) of sheer, white silk decorated with a painted design. The outer kimono (*uwagi*) is very large to accommodate the many layers of kimono worn under it, the abnormally long skirt swirling out fanwise around the wearer's feet. This, too, is made of rich brocade, its design and colours being a matter of personal taste. Under the *uwagi* is a plain purple kimono, and under that a robe known as the *itsutsu-ginu,* which has multiple bands of coloured silks (usually five) attached at the edges of the sleeves, at the neckline, and at the hem, giving the appearance of several robes worn one over another. No special interest attaches to the *hitoe* kimono worn under the *itsutsu-ginu* or to the *kosode* worn next to the body, but the divided skirt (*naga-bakama*) that completes the costume is an extremely picturesque garment. Made of stiff, red cloth and fastened high up under the breasts, the *naga-bakama* covers the feet in front and is carried out in a train in back. Worn with the *jūni-hitoe* is an elaborate coiffure known as *suberakashi,* and affixed directly over the forehead are special hair ornaments consisting of a lacquered, gold-sprinkled comb surmounted by a gold lacquered chrysanthemum crest.

Other types of dress formalized in the 12th century were the *noshi* (courtiers' everyday costumes) and the *kariginu,*

Figure 38: Japanese woman wearing an *uchikake*-type kimono. "The Courtesan Itsutomi Holding a Plectrum," print by Chobunsai Yeishi, *c.* 1794.

worn for hunting. Both of these garments were voluminous hip-length jackets worn with baggy trousers tied at the ankles. At this time also it became necessary to devise special costumes for the newly formed samurai caste. The *hitatare,* the formal court robe of samurai, and the *suo,* a crested linen robe designed for everyday wear, were characterized by V-shaped necklines accentuated by inner-robe neckbands of white. Several centuries later the samurai adopted the *kamishimo,* a striking jumperlike garment, with extended shoulders and pleated skirt-trousers, which was worn over the *hitatare.* This costume probably inspired a later fashion of wearing skirt-trousers (*hakama*) over a full-length black kimono, which, together with the

Other types of 12th-century formalized dress

short black *haori* coat, was until fairly recently the approved formal attire for Japanese men (Figure 37).

The basic kimono style adopted by Japanese women during the Nara period has remained amazingly close to that of the *p'ao* robes worn by the women of T'ang China. The practice of wearing a short-sleeved kimono (*kosode*) as an outer garment and belting it in with a narrow sash (*obi*) originated during the Muromachi period (Ashikaga shogunate; 1338–1573), when samurai women began to wear a voluminous outer kimono (*uchikake*) as a kind of mantle (Figure 38). Eventually, the *kosode* came to be worn only by married women, the long-sleeved *furisode* being reserved for young unmarried girls. The wide *obi*, tied in a variety of ways and fastened with an often intricately carved toggle (*netsuke*), was adopted in the early 18th century, and it was at this time also that women first began to wear the short *haori* coat, which has come to be an important feature of Japanese women's dress.

The *yukata*

The *yukata*, which is worn by both men and women, is a cotton kimono with stencil-dyed patterns (usually done in shades of indigo) that was originally designed for wear in the home after a bath. Because it has become accepted practice to wear *yukata* on the street on warm summer evenings, the cottons designed for them have become increasingly handsome.

Traditional Japanese footwear includes sandals, slippers, and wooden clogs (*geta*) worn with the *tabi*, a sock with a separate section for the big toe. (Pa.S./D.Y.)

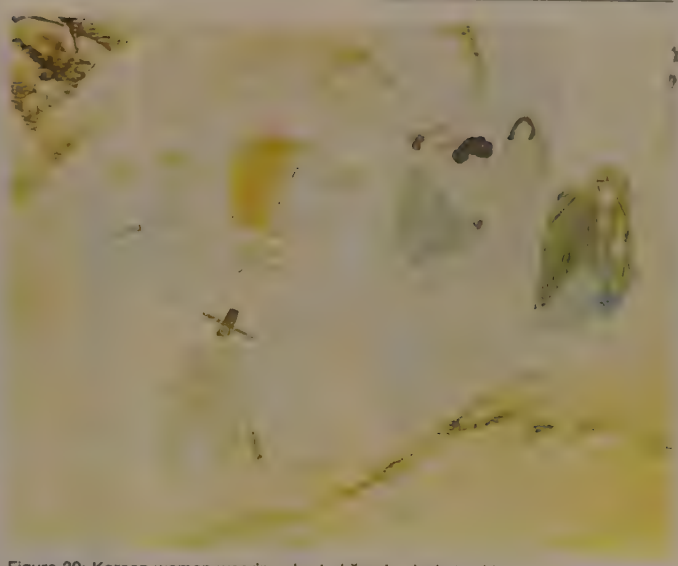

Figure 39: Korean women wearing short *chŏgori*, a jacket, with raised up skirts. Inked and coloured leaf from an album of 30 leaves by Sin Yun-bok (1758–?). In the collection of Chun Sung-woo, Korea.

KOREA

Some of the basic elements of modern traditional dress in Korea, the *chŏgori* (jacket), *paji* (trousers), and *turumagi* (overcoat), were probably worn at a very early date, but the characteristic two-piece costume of today did not begin to evolve until the period of the Three Kingdoms (*c.* 57 BC–AD 668). During the early part of this period both men and women wore tight, waist-length jackets and short, tight trousers; and it is believed that the Koreans' traditional fondness for white clothing dates from this period.

Korean records state that special costumes for court wear modeled after those of T'ang China were adopted during the reign of Kim Ch'unch'u in the 7th century; but Chinese influence on Korean dress at this period is verifiable only in changes that occurred in the everyday costumes of the nobility. Noblewomen formerly had worn tight trousers and jackets (which continued to be worn by the poorer classes); now they began to appear in wide-sleeved, hip-length jackets, belted at the waist, and in full-length skirt-trousers. The corresponding dress for noblemen was a narrower, tunic-style jacket, cuffed at the wrists, belted, and worn with roomy trousers bound in at the ankles. The most striking evidence of Chinese influence at this time is to be seen in the style of the *turumagi* overcoat worn by noblemen, pictured in fresco paintings as a voluminous full-length garment made almost exactly like the *p'ao* robe of T'ang China. One-piece robes were never worn in Korea until the late 13th century, when the court was forced to adopt Mongol dress; after Mongol domination ended in 1364, Koreans wore the one-piece robe only at wedding ceremonies.

Everyday costumes of the nobility

In the 15th century, Korean women began to wear pleated skirts (*ch'ima*) and longer *chŏgori* (jackets), a style that was undoubtedly introduced from China. Noblewomen wore full-length *ch'ima* to indicate their social standing and began gradually to shorten the *chŏgori* until eventually it attained its present length, just covering the breast. This style made it necessary to reduce the fullness of the skirt somewhat in order to make it possible to extend it almost up to the armpits, which remains the fashion (Figure 39).

The adoption of Chinese-style mandarin squares as emblems of rank for civil and military officials (who wore them on their *turumagi*) appears to have been the only notable example of Chinese influence on men's dress at this period. Otherwise, few changes were made until 1894, when class distinctions were relaxed by government decree. It was at this time that the *turumagi* was shortened and narrowed to its present form.

The most picturesque costume of modern Korea is that of men of leisure, *yangban*, who are past 60 years of age. The *yangban* wear white almost exclusively, their costumes consisting of full trousers tied at the ankles with ribbons, over which is worn a short *chŏgori* and a fitted vest and, over all, a loose *turumagi*, which falls just below the knees and is tied at the breast. The patriarchal appearance of the *yangban* (who is usually bearded) is accentuated by a black horsehair hat, its flat brim and high crown giving him somewhat the appearance of an American colonial Pilgrim Father. Younger men wear a similar costume (though not the hat) in gray, light blue, or light brown.

Women's costumes feature a bolero-style white *chŏgori*, finished off at the neck by a figured band or ribbon that ties from left to right, and high-waisted *ch'ima*, which, in formal costumes, is a full, billowing garment made of beautifully patterned silk.

SOUTH ASIA

The Hindu population of South Asia comprises about 2,000 castes whose members wear clothes and ornaments that clearly indicate their caste. The subject of dress, therefore, cannot be dealt with satisfactorily in a few paragraphs. Some of the principal features of upper-class Hindu and Muslim dress and the history of their development can, however, be sketched briefly.

The dhoti and sari

The ancient origin of two of the most characteristic garments of modern India, the dhoti worn by men and the sari worn by women, is verifiable in sculptured reliefs as far back as the 2nd century BC. Both men and women are pictured wearing a long piece of cloth wrapped around the hips and drawn between the legs in such a fashion that it forms a series of folds down the front. The upper bodies of both men and women were unclothed, though women wore a narrow cloth girdle around the waist. Men are pictured wearing large turbans, women with head scarves that fall to the hips. Women also wore a great amount of jewelry—bracelets, anklets, and girdles—but men's ornaments consisted solely of bracelets.

No major change in costume appears to have been made until the 12th century, when the Muslims conquered northern and central India. In this part of the subcontinent, radical new dress styles were adopted to conform with Muslim practice, which required that the body be covered as completely as possible. Men's costumes thereafter consisted of the *jāmah*, a long-sleeved coat that reached to the knees or below and was belted in with a sash, and wide trousers known as *isar* (Figure 40, right). These garments and the *farjī*, a long, gownlike coat with short sleeves, which was worn by priests, scholars, and high officials, were made of cotton or wool, silk being forbidden to men by the Qur'ān. Somewhat modified, these

traditional styles continue to be worn by upper-class men of Pakistan and Bangladesh.

Muslim women's garments

Women's garments, dictated by the Muslim conquerors, consisted of wide-topped trousers snugly fitted around the calves of the legs, a long shirtlike garment, and a short, fitted outer jacket. Silk was not forbidden to women; and highborn women, forced to spend their lives in seclusion, devoted much time and money to their costumes. The Mughal emperor Akbar's Rājput wives, inspired by the profusion of luxurious fabrics available in India, designed a graceful new style of dress, which Muslim women adopted forthwith. This costume consisted of an open-front pleated skirt, or *ghāghrā,* worn with a long apronlike panel over the front opening, and a short-sleeved, breast-length blouse called a *colī* (Figure 40, left). The *ghāghrā* and *colī* continue to be basic elements of Muslim women's dress, the loose front panel replaced by the traditional sari, which is worn as an overgarment, one end draped around the hips, the other carried up over the shoulder or head.

Dress in southern India was little affected by Muslim rule in the north. The dhoti continued to be worn by most Hindu men (it is forbidden to some castes), and the sari by women. Some additions to these traditional costumes have been adopted. On formal and semiformal occasions many Hindu men wear a long, full-skirted, white cotton coat, which reaches to the knees and buttons down the front from top to bottom, over jodhpur-style white trousers; and most Hindu women wear a short *colī*-style blouse under a sari or with a long skirt under a loose waist-length bodice. (Pa.S.)

The nature and purposes of dress

Perhaps the most obvious function of dress is to provide warmth and protection. Many scholars believe, however, that the first crude garments and ornaments worn by humans were designed not for utilitarian but for religious or ritual purposes. Other basic functions of dress include identifying the wearer (by providing information about sex, age, occupation, or other characteristic) and making the wearer appear more attractive. Although it is clear why such uses of dress developed and remain significant, it can often be difficult to determine how they are achieved. Some garments thought of as beautiful offer no protection whatsoever and may in fact even injure the wearer. Items that definitely identify one wearer can lose their meaning in another time and place. Clothes that are deemed handsome in one period are declared downright ugly in the next, and even uniforms—the simplest and most easily identified costume—are subject to change. What are the reasons for such changes? Why do people replace useful, attractive garments before they are worn out? In short, why does fashion, as opposed to mere dress, exist?

Influence of social and economic standing on fashion

There are no simple answers to such questions, of course, and any one reason is influenced by a multitude of others, but certainly one of the most prevalent theories is that fashion serves as a reflection of social and economic standing. Thus, in relatively static societies with limited movement between classes, as in many parts of Asia until modern times or in Europe before the Middle Ages (or later in some areas), styles generally did not undergo major or rapid change. In contrast, when lower classes have the ability to copy upper classes, the upper classes quickly instigate fashion changes that demonstrate their authority and high position. During the 20th century, for example, improved communication and manufacturing technology enabled new styles to trickle down from the elite to the masses at ever faster speeds, with the result that more styles were introduced than at any other time.

Furthermore, the idea that fashion is a reflection of wealth and prestige can be used to explain the popularity of many styles throughout costume history. For example, courts have been a major source of fashion in the West, and clothes that are difficult to obtain and expensive to maintain have frequently been at the forefront of fashion. Ruffs, for example, required servants to reset them with hot irons and starch every day and so were not generally worn by ordinary folk. As such garments become easier to buy and care for, they lose their exclusivity and hence much of their appeal. For the same reason, when fabrics or materials are rare or costly, styles that require them in excessive, extravagant amounts become particularly fashionable—as can be seen in the 16th-century vogue for slashing outer garments to reveal a second layer of luxurious fabric underneath.

Similarly, impractical fashions that clearly demonstrate the wearer does not need to work, and indeed would find it difficult to do so dressed in such a manner, have often been considered beautiful. Examples include the Chinese practice of binding aristocratic women's feet, making it

impossible for the women to walk far, and the recurrent popularity in Europe of styles that limited a woman's ability to maneuver or move by confining her into frequently injurious corsets and weighting her down with excessive layers of petticoats and skirts. Women have traditionally been the targets of the most extreme forms of impractical fashion because they have frequently been viewed as little more than a frivolous ornament for a man's arm or household. The fact that a woman is dressed in such a manner proves not only that she does not work but also that her husband or father can afford to hire servants to work for her. Men have worn their share of impractical clothing, however. The late Gothic houppelande, for example, a courtly style worn by both sexes, was far too voluminous for peasants to work in, even if they could have afforded all the material necessary for its manufacture. The best illustrations of the new garment are found in *Les Très Riches Heures du duc de Berry,* at the Condé Museum, Chantilly, Fr. These show that the duke wore the houppelande down to the floor, but his servitors, who needed to move more freely, wore shorter gowns. Length thus provided an immediate signal of status.

The foregoing discussion does not attempt to be a comprehensive introduction to even one influence on fashion; it merely tries to suggest some of the ways in which costume can be analyzed and interpreted. Similar treatments of four other factors affecting fashion follow.

DISPLAY OF THE HUMAN PHYSIQUE

Male sexual display at its most blatant can be seen in parts of Papua New Guinea, where the men wear bamboo penis covers that are sometimes up to 15 inches long. The purpose is to impress both women and enemies, by showing that the warriors are more virile than their opponents.

Martial display

The competition between warriors has led to a great variety of additional adornments such as boars' tusks, animal skins, animal teeth, claws, feathers, shells, metal pieces, bamboo, and the use of paint. In general, the more naked a society is, the more body paint is employed to denote the warriors and the chiefs, with each rank having its individual pattern. In addition, in many societies, only after an individual has reached a certain age or satisfied some other requirements is he allowed to wear certain colours or decorations. Sometimes each item of adornment represents a specific achievement, so that the more decorations a man wears, the better, braver, or more powerful he is shown to be.

Figure 41: The impractical aspect of court fashion, as seen in the long sleeves and trailing gowns of 15th-century courtiers. The servants wear shorter gowns, an immediate sign of their status. Detail from "A Fishing Party at the Court of Holland," gouache by an unknown Dutch or Flemish artist, *c.* 1425. In the Louvre, Paris.

Such martial display in Europe reached its apex with the tournaments of the Middle Ages. The males spent fortunes on enameled armour, ostrich plumes, pearl-embroidered tabards, ornate saddles and horsecloths, fine mounts, their retinue of grooms and squires, weapons, tents, and their declamations or speeches. It was a formalized kind of warfare, and foreign ambassadors were invited to be impressed by the martial display of the king or prince. An audience of females was also essential, as they had to confer favours on the knights, and the lady of the tournament had to present the bejeweled prize to the overall victor.

Such blatant display as bamboo penis cases was typified in Europe by the codpiece. During the 14th century men started shortening their tunics until they reached the crotch. A special pouch, the codpiece, had to be created to fill in the gap between the hose at the top. Initially the codpiece was not padded, but it grew larger until by the 1540s the Spanish were wearing a vertical, or erect, codpiece. This style—and its spread to other parts of Europe—may be seen to be a reflection of Spain's new dominance in the Western world and its new wealth. Spanish pride and influence were manifested in vertical codpieces, but they were soon deflated by England's Queen Elizabeth I and her navy. Perhaps in recognition of the arrival of queens regnant in England and Scotland, as well as a queen mother regent in France, both men's and women's dress began to feature a more rounded, "feminine" silhouette, and codpieces began to be covered up. Soon, female width, in the shape of the farthingale, caused codpieces to disappear completely, as men's breeches were padded out to match the ladies' skirts.

A covered-up look then dominated male attire until the late 18th century, when the Neoclassical movement led to tighter, more revealing clothes. Skin-coloured knee breeches in buckskin became the rage, and waistcoats shrank, so that from the waist downward the male form was again on show. A naked style affected the army too; uniforms became skintight, and the male form was displayed most obviously in the Napoleonic period. Under Queen Victoria the frock coat concealed all such shocking elements as legs, waist, and bulge, which remained concealed until after World War II, when skintight jeans became the means for a renewal of male sexual display. By the 1990s, Lycra (trademark) had entered at least some men's wardrobes in the form of leisure wear, its clinging characteristics providing even more extreme "naked" outlines. Thus, since the 14th century in the West, the degree of exposure of the male body has alternated between total concealment and complete display.

Views on female display have also changed dramatically. In primitive societies wives were often loaded with copper necklaces, earrings and bangles to display the wealth of their husbands. Until the 20th century, Bulgarian peasants similarly bedecked the women in their families with coins, disks, pieces of mirror, and chains to show their economic status. Such practices may date back to ancient Greece, where it was the custom in Athens to dress statues of female goddesses with new clothes and jewels every year.

In antiquity total nudity was acceptable for both sexes in gymnasia, at funerals, and in temples. It was only with the rise of Christianity, and 600 years later Islām, that modest covering of the female form became compulsory. St. Paul wrote to Timothy that women should not display, "that women should adorn themselves modestly and sensibly in seemly apparel, not with braided hair or gold or pearls or costly attire but by good deeds, as befits women who profess religion." St. Peter expressed similar views, and St. Augustine of Hippo went even further by censuring makeup as well, although he allowed that a woman might adorn herself slightly to please her husband if the practice was carried out in private.

Modesty in women's dress

Once Theodosius I made Christianity compulsory in the Roman Empire in 381, Christian views on modesty dominated women's appearance, with the exception of the imperial court; imperial princesses—like the emperor—were permitted to continue decorating themselves in luxurious finery. Some Church Fathers and churchmen expected

fashions to cease to change at this point, but this was an unrealistic attitude from the first. The slow changes that did occur, however, did little to alter the modest style of women's clothing. Then Diocletian divided the Roman Empire into two parts, and Constantine I the Great founded another capital, Constantinople. Inevitably, each centre felt the need to establish its own identity in clothes and styles. Eastern Rome on the Bosporus adopted the Eastern taste for coloured and patterned fabrics, and in 552, when the emperor Justinian established the first silk-manufacturing industry in Europe in Constantinople, the city became renowned for its luxurious silks and brocades.

Meanwhile, western Rome suffered barbarian invasions and centuries of disorder, until it broke up into separate kingdoms. Once these new courts had established themselves, it was only a matter of time before they, too, started trying to outdress and outshine one another. The Anglo-Saxons, for example, wore loose clothes, but after the Norman Conquest a change followed. By the 1090s members of the Norman court had started wearing tighter-fitting clothes. This was achieved by cutting the garments on the bias and lacing them under the arm, with the result that the female figure in particular was outlined very obviously. Although abbots and bishops objected vehemently, the new fashion for displaying the physique continued unabashed. This style, which also featured exaggerated cuffs reaching the ground and waistlines down at the hips, dominated the 1100s. A looser gown with a normal waistline eventually ousted the fashion in the 1200s. This pleased the church, but the desire for change in the West was too well founded to fade away. By the 1340s exposure was back, this time with necklines so wide that they were almost off the shoulder. Moreover, the adoption of buttonholes from the Moors around 1250 had introduced the art of tailoring. Clothes could now be cut very tight and still be easily removed. Shaped seams evolved, waistlines dropped again, and the possession of a shapely figure was essential for both men and women (although men were permitted to use padding over the chest to give them a curved frontage). When Edward III defeated the French at Crécy in 1346, the chronicles said it was God's punishment on the French court for wearing such shocking styles, a comment that completely overlooked the fact that the Anglo-Norman victors were wearing exactly the same fashion.

Movement toward tighter-fitting clothes

By 1364 the houppelande gown had been invented, which did conceal the human figure better, but by 1400 the church was complaining about the excessive amount of material used in the skirts and sleeves of the houppelande. Some houppelandes concealed the neck; others had a curved neckline that was almost as wide as that of the 1340s. This latter style was worn exclusively by women. Women's waistlines were higher, too, emphasizing the bosom and making the differences between the sexes obvious. The exposure of the female neck became almost permanent in court circles thenceforth. A V-shaped neckline that dipped to the bust and had to be filled in with a stomacher began to replace the wide one by the middle of the 1400s. By the 1490s the square neckline of the Tudor style, which exposed the female throat and chest from shoulder to shoulder, had become the dominant mode. When ruffs began to develop, there was a spell of concealment for the female neck, for the cartwheel ruff was built right up to the throat in the 1580s; but by 1588 Elizabeth I of England had adopted the open-fronted Medici ruff, and the exposure of the woman's throat returned as a permanent feature of court style. (Puritan ladies of course concealed the neck completely, but they tried to avoid fashion styles and trends.)

The majority of the changes in fashion that occurred from the late 1400s to the late 1700s were fueled by court competition rather than by changing attitudes about appropriate amounts of display or modesty for women. The dominant state usually affected the styles worn at other capitals during this period. It was not until the end of the 18th century, when Neoclassical taste came to the fore, that the exposure of the female form was again a major issue.

When the English novelist Fanny Burney visited Paris in April 1802, her modest wardrobe was found too full: "Three petticoats! no one wears more than one! Stays? everybody has left off even corsets! Shift-sleeves? not a soul now wears even a chemise." To be purely classical, young women adopted high-waisted, diaphanous gowns, with only one petticoat beneath; the whole of the female frame was flaunted in a manner that seemed indecent to the older generation. Stays were not abandoned for long, however, as the new slim line required a sylphlike, figure, and any bulges of the stomach or bottom had to be suppressed. In any case, this classical vogue was not strictly accurate. The gowns were not draped on or pinned together as in antiquity but had a tailored bodice and cap sleeves. In general, revivals of past styles only approximate a look and never adopt the whole vocabulary.

With the rise of Romanticism a more covered-up style developed. Women had to become demure maidens, hiding their faces in poke bonnets and concealing their figures under petticoats and shawls. By 1856 the cage crinoline of steel took this isolation of the saintly maiden to its extreme, by making her unapproachable. At this point, haute couture entered the fashion scene. The great couturier Charles Frederick Worth flattened the front of the crinoline in 1864, and in the winter of 1867–68 he abolished the garment completely in favour of long trains. In 1869 he revived the Baroque bustle but five years later slimmed the skirt down and launched the longer, fitted cuirass bodice. The narrower skirts allowed the outline of a woman's legs to be seen for the first time in 50 years. It was a brief pleasure. In 1881 Worth revived bustles, this time in a squarer, sharper look, and the exposure of the female person was ended. Only in evening dress was the bosom disclosed, and anything below that point was unseen and unmentionable.

The demure look of the Romantic period

Also influential at this time was the vogue for women's sports. There had been a similar strong fashion for women playing sports in the 1770s and '80s, when archery, shooting, lawn bowling, and riding were all permitted. The Romantics later ruled out such activities as too masculine, but by the 1860s sports were creeping back for women, and some freer clothes evolved in consequence. Amelia Bloomer's reformed trousers for women did not become fashionable, but they were adopted by women gymnasts and sea bathers. Short skirts were designed by Worth for walking, and short hems spread into golfing, shooting, and tennis outfits, while bloomers were worn for cycling. The trend to make clothes more comfortable and to reduce the amount of underwear worn was initiated by this sporting activity. When women could rush about without fuss playing croquet, rounders, and hockey during the day, they did not want to have to don elaborate confections for dinner and evening. This desire to lighten the wardrobe took time to spread through the world of fashion, however, and it was not until the next classical revival in 1907–08 that evening dresses became simpler.

The acceptance of less cumbersome costumes for sports affected swimwear, too, and, once the designer Gabrielle "Coco" Chanel made suntans the rage, exposure of the female form became almost total. Sunbathing suits revealed more of the female anatomy than any costume in history since antiquity. (Whereas in the past ladies had gone to great lengths to avoid being browned by the sun, for a sunburned complexion was the mark of a peasant, there was an almost universal vogue for sun worship in the West from the 1920s until the 1980s, when such exposure of the physique began to be warned against, with doctors stressing the dangers of skin cancer.) The backless evening dresses of the 1920s and '30s required a suntan to display and in cut were practically bathing costumes with skirts. The 1950s launched the bikini, which provided minimal coverage for women, and since then even total nudity became acceptable on some beaches.

Swimwear

GOVERNMENT REGULATION OF DRESS

Sumptuary laws. For thousands of years governments have tried to control spending by employing sumptuary laws. The first such law under the Roman Republic, the Lex Oppia, was enacted in 215 BC; it ruled that women could not wear more than half an ounce of gold upon

their persons and that their tunics should not be in different colours. Most Roman sumptuary laws tried to control spending on funerals, banquets, and festivals; there were no further laws on dress until the emperor Tiberius ruled that no silken clothing should disgrace men. Such a soft fabric as silk was considered fit only for women; the Roman male was to be a tough and severe character who did not wear Eastern imports. By 303 AD, however, Diocletian's Edict on Maximum Prices mentions the *sarcinator*, a professional tailor who made only silk clothing, and so the business seems to have expanded despite Tiberius.

It was not until the 1300s, when national governments had been established in France and England and city-states formed in Italy, that sumptuary laws appear in any number in the West. In 1322 Florence forbade the wearing of silk and scarlet cloth by its citizens outside their houses. In 1366 Perugia banned the wearing of velvet, silk, and satin within its boundaries. The impact of such legislation can be seen in the wardrobe of Francesco di Marco Datini, a merchant of Prato. Despite the fact that he had business houses from Avignon to Spain as well as in Italy and was the equivalent of a modern millionaire, his finest gowns in 1397 were made of woolen cloth, their only hint of luxury provided by a taffeta lining. The law did not permit the commercial classes to own garments made of velvet, brocade, silk, or other rich fabrics.

Dual purpose of sumptuary laws

Whereas Roman sumptuary law had applied equally to all women and all men, in western Europe the laws were more discriminatory, restricting the richest fabrics, furs, and jewels to the aristocracy. Thus, in England in 1337 Edward III ruled that no one below the rank of knight could wear fur. The same law also decreed that only English-made cloth could be worn in England. This dual role of ensuring class distinctions and banning imported goods was common in sumptuary law. In 1362 Edward III issued another edict aimed at preventing people from dressing above their station. Merchants could wear the same clothes as an esquire or knight, but only if they were five times wealthier. Yeomen and below could not wear silk, cloth of silver, chains, jewels, or buttons (which were then made of expensive materials or gems). They were not to wear the short coats or tunics worn by noblemen. Carters, plowmen, shepherds, oxherds, cowherds, swineherds, dairymen, and farm labourers were to wear only russet cloth at a shilling a yard and undyed blanket cloth. Thus, farming folk were restricted to natural wool tone and russet, and they continued wearing such colours into the 20th century. Only lords might wear cloth of gold and sable furs. Esquires and gentlemen were not allowed velvet, satin, ermines, or satin damask unless they were sergeants of the royal household. Women could not wear gold or silver girdles, nor foreign silk head covers.

Similar laws explicitly stipulating the fabrics, styles, and colours to be worn by men and women of particular social or economic standing were issued in Spain and France as well. Furthermore, in France and England it was often claimed that such laws were issued for moral or religious reasons. For example, in 1583 Henry III of France decreed that in order to regularize and reform clothing, which was dissolute and superfluous, the wearing of precious stones and pearls on garments was restricted to princes. The richest fabrics allowed were velvet, satin, damask, and taffeta, all without any enrichment beyond silk linings. Bands of embroidery in gold and silver were banned. Henry III stressed that God was angry because he could not recognize a person's quality from his clothes. A similar excuse had been given in England in 1463 when Edward IV issued a sumptuary law on the grounds that God was displeased by excessive and inordinate apparel.

In the 17th century sumptuary laws were increasingly used to restrict foreign imports and had less to do with status than with trade wars. France, for example, was trying to set up its own silk industry and therefore banned Italian silks and English cloth. Italy and Spain, however, continued issuing class restrictions on dress until 1800.

Other types of legislation. In Russia clothing law was used to modernize the country. As soon as Tsar Peter I the Great returned from working in the dockyards of Amsterdam and London in 1697–98, he began requiring his princes to shave their beards. Then in 1701 he ruled that his subjects must adopt Western dress. Peter's command applied to both men and women but at first affected only members of the court and government officials. Merchants and peasants continued to wear traditional garments into the 19th and sometimes even the 20th century.

Use of clothing laws to encourage modernization

A similar attempt to modernize a nation through its clothing was made by Mustafa Kemal (known as Atatürk) in Turkey in 1925. Laws were passed banning the fez and requiring Panama hats to be worn. To some Turks, wearing Western attire instead of traditional garments was akin to heresy, but Mustafa Kemal succeeded in changing dress, in the cities at least. With the rise of fundamentalist Islām in the late 20th century, Western styles of dress again became a subject of controversy in Turkey. Some Turks demanded that women be required to cover their heads and men to wear beards. The government responded by imposing fines on women who wore head scarves as a Muslim gesture.

In other countries, clothing legislation has been passed to ensure the preservation of local identity and dress in the face of encroaching foreign cultures. In Iran, for example, following the Islāmic revolution in the late 1970s, laws that had encouraged Western customs and clothing were replaced by ones that enforced traditional Islāmic codes of dress and behaviour.

In the West the most recent government restrictions of clothing occurred during World Wars I and II, when shortages prompted the establishment of clothes-rationing systems.

REBELLION

Rebellion against the established or dominant fashion has been a constant theme in the history of costume. The reasons prompting such rebellion are various: to shock, to attract attention, to protest against the traditional social order, to avoid current trends and thereby avoid dating oneself. One of the earliest forms such rebellion has taken—and continues to take—has been that of women adopting male dress. By donning men's clothing, women have been able to challenge the status quo and participate in activities or roles traditionally perceived as masculine.

Women's adoption of male dress

There are several examples of women in antiquity who put on male armour to go to war. Herodotus cites Queen Tomyris of the Massagetai, who led her troops against Cyrus II the Great of Persia and killed him in 529 BC. Herodotus also records Queen Artemisia I, admiral of her own ships in 480 BC when she sailed with the navy of Xerxes I, who valued her opinions highly. Queen Boudicca of the Iceni tried to drive the Romans out of Britain in AD 61. The Saxon King Alfred appointed his daughter Aethelflaed commander in chief of the west, and she successfully liberated Derby and Leicester from the Danes in 917–918. In 1080 Duchess Gaita of Lombardy rode in full male armour alongside her husband. Princess Anna Comnena of Constantinople called Gaita a "formidable sight."

The practice of women wearing male dress has not always been accepted, however. In 1429 Joan of Arc adopted male clothes, and this wearing of male dress was included among the charges against her when she was tried by the bishop of Beauvais. The bishop said her claim that God, angels, and saints had told her to don male attire was contrary to the modesty of women, was prohibited by divine law, and was forbidden by ecclesiastical censure on pain of anathema. If her voices had told her to dress as a man, why had she chosen such short, tight, and dissolute garments as tabards, cottes, and elaborate hats, and why had she cut her hair like a man, with a shaved neck? Joan confessed to error and was ordered to wear women's clothing. Nevertheless, she reverted to male dress in prison, which the bishop claimed was a sign that she had reneged on her confession. On further questioning, Joan recanted her confession and was condemned to be burned.

It has not been only for reasons of war or to defend their homes that women have adopted men's clothing. British historian Henry Knighton complained in 1348 that some 40 or 50 English ladies were arriving at tournaments in male dress and armour to parade in the intervals, so that they might share in the glory of a tourney. Knighton

Figure 42: Madame de Saint-Baslmont, a 17th-century French noblewoman who adopted men's clothing and armour to defend her estates during the Thirty Years' War. "Madame de Saint-Baslmont on Horseback," oil on canvas by Claude Deruet, *c.* 1640. In the Musée Historique Lorrain, Nancy, France.

Musee Historique Lorrain, Nancy; photograph, Gilbert Mangin

claimed that God so was incensed at this behaviour that he sent thunderstorms to drive the women indoors.

Women also have found men's clothing more suitable for certain types of work. The women pirates Mary Read and Ann Bonney donned male trousers when at sea until their capture in 1720. In 1745 Britain's Hannah Snell joined the marines and served in India for five years, wearing a male uniform all the time. It was not only a wish for action that made some women adopt male clothing. In the 19th century there were several examples of women doing so in order to earn a man's wages, which were higher than a woman's. In 1818 Helen Oliver in Scotland met a plowman who turned out to be a woman, so she copied the idea and, borrowing her brother's suit, went off to work as a plasterer. By 1866 Helen Bruce had been working in male dress since she was 17, as an errand boy, shop lad, ship's stoker, tallyman at a mine, and clerk. As women were not allowed to become doctors, Miranda Barry dressed as a man and obtained a degree in medicine at the University of Edinburgh. She then became an army surgeon and ended her career as inspector general of military hospitals in Canada in 1857, after serving in the Crimean War.

Rebellion against contemporary fashions

Cultural rebels have often chosen to adopt antique fashions in order to reject, or at least distance themselves from, their own time or to identify with what they believed to be a superior age. Sometimes such borrowings from the past become a widely accepted fashion, as in the late 18th and early 19th centuries, when Neoclassicism was at its height and women's gowns were supposed to be based on ancient Greek and Roman styles. More frequently, however, the practice remains on fashion's fringes. It has nevertheless persisted since ancient times.

The Roman empress Messalina Valeria led a revolt against Roman dress by wearing Greek clothes herself (coloured Ionic chitons fastened down the arms with bejeweled brooches) and by wearing her hair in Greek hairnets and tiaras. Her male friends similarly wore coloured Greek cloaks instead of the chalky white Roman toga. More recently, in the 1960s and '70s, many young men and women in the United States adopted the "granny" look. By wearing garments that had been popular 100 years before, such as collarless shirts, long, high-waisted cotton dresses, and small, metal-rimmed "granny" glasses, the wearers expressed their disdain for the contemporary adult establishment and their dress.

Artists have similarly often preferred older fashions, but this is usually because they wish to achieve an effect of timelessness. Leonardo da Vinci wrote in his *Treatise on Painting*, published long after his death, that art should avoid the fashion:

> As far as possible avoid the costumes of your own day.... Costumes of our period should not be depicted unless it be on tombstones, so that we may be spared being laughed at by our successors for the mad fashions of men and leave behind only things that may be admired for their dignity and beauty."

He showed how to tackle the problem in his portrait of "Mona Lisa" (Louvre, Paris), by dressing her in a coloured shift, loosely pleated at the neck, instead of the tight clothes that were then popular. This concept spread through western Europe over the following centuries. In the 17th century many rulers were depicted as Roman emperors in Roman armour, considered the ideal symbol for the age of absolute monarchy, and it became a sign of sophistication to look Roman in one's portrait, even if the sitter was wearing a periwig at the same time. (People were reluctant to change their hairstyles to an antique manner, as they had to wear them outside the artists' studios.) In the 18th century, aristocrats had copies made of the clothes in their ancestors' portraits to wear at masquerades and in their own portraits. Although the practice was a cultural revolt against the tyranny of contemporary fashion, the clothing was generally expressed with current tastes in mind. Artistic reform of dress in the 19th century was initiated by the Pre-Raphaelites in 1848, and by the 1860s the "Aesthetic" dress they promoted began to be adopted in sophisticated societies. The invention and widespread use of photography has effectively abolished any further need for the establishment of a specific clothing policy for art in opposition to that of high fashion. It has become acceptable for painters and sculptors—like photographers—to render contemporary fashions accurately. Extreme trends are still usually avoided, however, and portraitists of royalty often use uniforms and robes of orders of knighthood to confer a historical character.

The use of underwear as outerwear

The desire to shock has led to many rebellions in fashion. In 1783 Queen Marie-Antoinette introduced her revolutionary white muslin chemise dress—to the horror of the French silk industry. It scandalized the elderly and the conservative, who considered the chemise an undergarment, but it changed the prevailing mode of dress from one featuring hoops and brocades to the Neoclassical style emphasizing plain white muslin and the natural figure. Such use of underwear as outerwear has been recurrent in fashion history and has continued into modern times, as

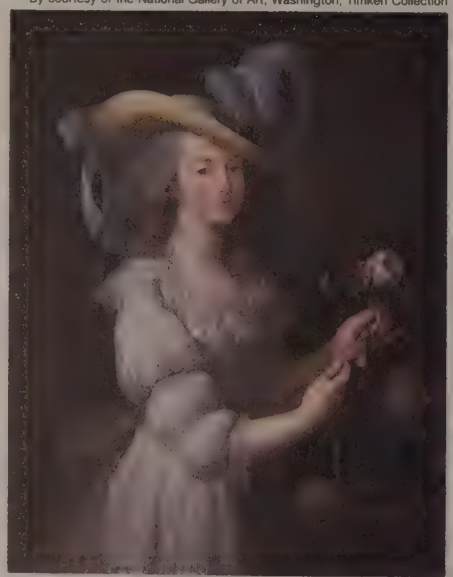

Figure 43: Queen Marie-Antoinette wearing the revolutionary white muslin dress that shocked conservative society. "Queen Marie-Antoinette," oil on canvas, attributed to Élisabeth Vigée-Lebrun, *c.* 1783. In the National Gallery of Art, Washington, D.C.

can be seen by the popularity of the bustier among young women in the 1980s.

Similarly, the desire to shock has remained a constant, especially among the young, who since World War II have had a significant influence on the fashion scene. Postwar teenagers have had both the money and the leisure time necessary to reject the established order and to devise a look of their own. Included among the styles they introduced are the T-shirts and jeans of the 1950s, the long-haired hippie look of the 1960s, and the punk look of the late 1970s.

EXOTICA

Like rebellion, the adoption of foreign elements has been a constant theme in the history of dress, and it too dates to antiquity. The first exotic fabric to reach the West was silk from China, which the Persians introduced to the Greeks and Romans and which has remained popular to the present. Another early import was the caftan coat, which is believed to have originated in Central Asia and which appeared among the Hittites, the Assyrians, and the Medes and Persians by 700 BC. During the Hellenistic period Greek tunics were introduced into the Middle East, but the caftan continued to be worn in Persia. The caftan eventually made its way to Russia, where it was described by the Arab traveler Ibn Fadlan in AD 922 when he saw a Viking chief's funeral on the Volga; the chief's body was dressed in a caftan of cloth of gold with golden buttons and a gold cap trimmed with sable. The Turks also adopted caftans, and they then brought the style to Hungary and Poland when they conquered those lands. Subsequently, there were occasional vogues for Turkish dress in Italy, Germany, and England, and the caftan became the model for later Western garments featuring fitted backs and open fronts.

Introduction of kimono and pajamas

The Japanese kimono entered the Western wardrobe in the 17th century. The English called the garments Indian gowns, probably because the East India Company imported them, but the Dutch more accurately called them Japanese coats. The garment was also termed a nightgown and a banyan and became fashionable for undress. The diarist Samuel Pepys bought himself an Indian gown on July 1, 1661, for 34 shillings. He further recorded that on Nov. 21, 1666, "I to wait on Sir Ph. Howard, whom I find dressing himself in his night-gown and Turban like a Turke." Strictly speaking, the Indian gown was meant to be worn for informal, private occasions, but a superior like Sir Philip Howard could wear such clothing to receive underlings, though they had to be fully dressed to attend him. The first nightgowns were cut loose like the Japanese originals, but in the late 18th century they became more fitted and tailored like coats. Such dressing gowns have remained fashionable and are now known as housecoats, bathrobes, wraps, and negligees depending on the material used. Indian pajamas, a soft cotton suit consisting of trousers and a loose, fitted jacket fastened down the front, were also introduced into Europe in the early 17th century. They, too, have remained popular for undress, although the style has sometimes also been adopted for more formal wear.

Figure 44: Silk Indian jacket and pajamas worn by an English earl. Detail from "William Feilding, 1st Earl of Denbigh," oil on canvas by Anthony Van Dyck, *c.* 1633. In the National Gallery, London.
By courtesy of the National Gallery, London

Many foreign garments are copied or borrowed of necessity. For example, when the Europeans invaded the Americas, the English and the French were quick to adopt Native American moccasins because few of the settlers knew how to make shoes. Similarly, in Canada the Indian snowshoe was essential wear, and many hunters and trappers adopted Indian fringe on their deerskin tunics as a practical embellishment that allowed rain to run off. When winter sports became fashionable in the 20th century, Eskimo padded boots and parkas (hooded jackets) were copied.

The modern Western wardrobe can include elements of Asian, African, and Native American dress. Similarly, non-Western cultures have adopted some Western garments, particularly the Western-style suit for business wear. In the future, as improved transportation and communication technology effectively shrink the size of the world, foreign influences on dress will no doubt continue to be introduced with increasing speed and influence.

(D.J.A. de M.)

JEWELRY

Jewelry consists of objects of personal adornment prized for the craftsmanship that went into their creation and generally for the value of their components as well. Through the centuries and from culture to culture, the materials considered rare and beautiful have ranged from shells, bones, pebbles, tusks, claws, and wood to so-called precious metals, precious and semiprecious stones, pearls, corals, enamels, vitreous pastes, and ceramics. In certain eras artist-craftsmen have sometimes placed less emphasis on the intrinsic value of materials than on their aesthetic function as components contributing to the effect of the whole. Thus, they might fashion a brooch out of steel or plastic rather than gold or platinum. Furthermore, in addition to its decorative function, during much of its history jewelry has also been worn as a sign of social rank—forbidden by sumptuary laws to all but the ruling classes—and as a talisman to avert evil and bring good luck. During the Middle Ages, for example, a ruby ring was thought to bring its owner lands and titles, to bestow virtue, to protect against seduction, and to prevent effervescence in water—but only if worn on the left hand.

Materials and methods

The first materials used to make objects for personal adornment were taken from the animal and vegetable world. The material taken from the animal world, in a natural or processed form, constituted the actual adornment, whereas vegetable fibres served as its support. A great variety of shells and pieces of shell were used during the prehistoric age and are still used in certain island and coastal cultures to make necklaces, bracelets, pendants, and headdresses. In the inland regions the first materials used for personal adornment came from mammoths' tusks, the horns of reindeer and other animals, and, later on, amber and lignite.

All materials that have been used over the centuries for the manufacture of jewelry have undergone to some extent mechanical, physical, or chemical treatment for the purpose of transforming their raw shapes into shapes that, in addition to being functional, also satisfy certain aesthetic concepts.

METALS

Gold, silver, and platinum

Precious metals and their properties. Of gold's properties, when it was first discovered (probably in Mesopotamia before 3000 BC), it was the metal's malleability that was a new phenomenon: only beeswax, when heated to a certain temperature, could be compared to it. Gold's molecules move and change position in accordance with the stresses to which it is submitted, so that when it is beaten it gains in surface area what it loses in thickness. In modern jewelry, gold can take on a variety of hues when it is alloyed with other metals: water green, white, gray, red, and blue.

After gold, silver is the metal most widely used in jewelry and the most malleable. Although known during the Copper Age, silver made only rare appearances in jewelry before the classical age. In general, silver was, and still is, used in jewelry for economic reasons or to obtain chromatic effects. It was often used in the 17th, 18th, and 19th centuries, however, as support in settings for diamonds and other transparent precious stones, in order to encourage the reflection of light.

Another rare metal, whose use in jewelry is fairly recent, is platinum. From the 19th century onward this metal was used ever more frequently in jewelry because of its white brilliance and malleability, as well as its resistance to acids and its high melting point.

Modern jewelry, such as that designed by early 20th-century artists, introduced nonprecious metals such as steel.

Sheet metal, embossing, openwork, and granulation

Metalwork. The basic components of jewelry have always consisted of sheet metal, metal cast in a mold, and wire (more or less heavy or fine). These components take on the desired shape by means of techniques carried out with the help of tools. Gold in its natural state was beaten while hot or cold and reduced to extremely thin sheets (this operation could be performed with stone hammers). The sheets were then cut into the desired sizes.

Examination of the most ancient pieces of jewelry shows that one of the techniques used most widely in decorating metal sheets for jewelry was embossing (relief work). Throughout the centuries embossing techniques have remained substantially unchanged, although in modern times mechanization has made possible mass production of decorative parts of jewelry, with great savings of time and labour but with a corresponding lack of art.

In repoussé the relief is pressed (in a negative mold) or hammered out from the reverse side of the gold sheet and then finished off on the right side with a hammer or engraving tool. For half-modeled or completely round reliefs, the gold leaf was pressed onto wooden or bronze models. Completely round objects were made in two pieces and then welded together.

Another embossing, or relief, technique is engraving, which involves impressing designs into the metal with a sharp tool.

Decorative openwork designs can be created by piercing the gold leaf. In the Roman period this technique was called *opus interassile*.

Granulation is a decorative technique in which small or minute gold balls (with diameters ranging from $1/60$ to $1/180$ of an inch) are used to form silhouettes on smooth or embossed metal.

Casting from precious metals has always been rare. When the relief was to be visible only from one side, the metal was poured into the cast and, when hardened, touched up with a graver. When the relief was to be fully modeled, the cire perdue (lost-wax) process, involving casting from a wax mold, was used.

Metal wire and filigree

Gold and silver wire, according to its function, can be made into various sizes, shapes, sections, and weights. It can serve to join, to support pendants of varying importance, to make necklaces and bracelets, or to alternate with other decorative components.

From the 3rd millennium BC through the present day, chains—ranging from the simple type, consisting of a series of round or oval rings, to one of the oldest elaborations, the "loop in loop," or square, chain—have offered goldsmiths the widest field for decorative imagination.

Filigree is a form of decoration made exclusively from fine gold or silver wire welded onto the surface of an object made of the same metal or done in openwork (without a background). The decoration to be carried out is designed first on a model with a flat or curved surface identical to that on which the completed filigree is to be welded or to the unsupported shape that it must assume. It can be made from smooth wire or from a ropelike plait or from a series of small hemispheres. A more complicated type of filigree consists of metal wire made in the shape of beads called granulated filigree.

After having been prepared separately, the different parts that make up a piece of jewelry are put together. In primitive jewelry this was done mechanically, by inserting beaten pins, by bending and beating the parts to be fastened together, or by binding them with gold wire or tape. Welding is a technique belonging to a more highly developed stage of ancient goldworking (end of the 3rd millennium BC).

Enamel work. In enamel work, powdered glass coloured with metal oxides diluted with water and adhesive is applied to certain parts of the piece of jewelry that have been cut lower or surrounded with a raised rim made of gold, silver, or copper. The object is then heated until the glass melts and adheres to the metal. As the enamel gradually cools, it crystallizes and, when smoothed, takes on greater lustre and colour. The enamel applied to jewelry can be opaque or translucent. By letting light through, transparent enamel catches reflections from the metal to which it is applied and makes visible any engraving done on the metal. Enamel is also distinguished according to the way it is applied, as in cloisonné, champlevé, basse taille, painted, and *plique à jour*.

Enameling preceded the polychromy created by precious stones. In the beginning, in Egypt, Greece, and the Sāsānian period in Iran, unpolished enameled parts of jewelry were often used to imitate lapis lazuli or malachite.

Niello technique

To a limited extent, jewelry also was decorated with the niello technique (from the Latin *nigellus*, an adjective derived from *niger*, meaning black). This consists of cutting grooves in gold or silver with a graver and then filling these with a powder made of red copper, silver, lead, sulfur, and borax. When heated, the powder melts and fills the grooves, adhering to the metal. After the piece has cooled, the surface is smoothed and polished, and the design shows up in black.

GEMS

In addition to gold, silver, and platinum, the precious materials most widely used in jewelry are gems—any precious or semiprecious stone. By definition this group also includes some animal and vegetable products with precious characteristics, such as amber, pearls, and coral. Conventionally, the following are classified as precious stones: diamonds, rubies (corundum), emeralds (beryl), and sapphires (corundum). To these, however, can be added chrysoberyl, topaz, and zircon because of their hardness and their refraction and transparency index.

Use of diamonds, rubies, and sapphires

The properties of gems. Diamonds have the highest refraction index, and those used for jewels are very transparent. Diamonds from Indian deposits were known in ancient times; in the West the limited use of diamonds began in the late Middle Ages. Diamonds for jewelry are graded on the basis of colour from blue-white to yellow. Grading also is done on the basis of purity, which varies from perfectly clear, extremely pure stones to those with many impurities and flaws. Large demand provided an incentive for the production of false diamonds (as well as other stones) as early as 1675 in Paris.

Mogok rubies, from Myanmar (Burma), are the most highly prized because of their bright red colour (pigeon blood). Those from Thailand are usually a more brownish colour, while those from Sri Lanka tend toward violet. Production of synthetic stones is far greater than the sup-

ply of natural rubies. The physical and optical properties of synthetic and natural rubies are so similar that it is difficult to distinguish between them.

The sapphire (blue variety of corundum) is considered one of the most valuable of precious stones. A sapphire's colouring usually indicates its origin. Those from Myanmar are deep blue. The Kashmir (Indian) sapphire is cornflower blue and is highly prized, being quite rare. Sapphires from Thailand are very similar in colour to those from Myanmar; those from Sri Lanka are of different shades but incline toward violet. Sapphires, like rubies, can be cut so that, in the light, a beautiful, luminous six-pointed star appears on the surface of the gem. Star sapphires and rubies are semi-opalescent. Synthetic sapphires and rubies are produced by the same industries.

Use of emeralds

The green emerald is a precious stone used since very ancient times. There is documentation of its presence in Egypt during the life of Pharaoh Sesostris III in the 19th century BC. At the end of the 16th century, emeralds from South America were brought into Europe. On the American continent, the first peoples to use emeralds were those belonging to the pre-Columbian civilizations, in particular the Inca. In 1935 in the United States (Chatham) and in Germany (Farbenindustrie), synthetic emerald crystals were made with characteristics similar to natural ones.

Among the beryls, mention must be made of morganite (pink beryl) found in various shades of peach-blossom pink. The main deposits are in California and Madagascar.

The two best known and most widely used varieties of chrysoberyl are alexandrite (transparent) and Oriental cat's-eye (opaque). Because of its great power of absorption of certain colours, alexandrite looks green in daylight and reddish purple in artificial light. The cat's-eye is a yellowish green colour and is characterized by a luminous line. The intensity of the light in this line varies according to the brightness of the rays of light that strike it.

One of the most important gems with pure crystals is the topaz, used a great deal in jewelry. The honey-yellow variety is the best known, but there are also pink, red, blue, and the less-used colourless stones. The Oriental topaz (a corundum) and citrine quartz are also widely used. They are less rare than other kinds of topaz and, therefore, less expensive but create a similar effect.

Among the less-important and less-rare stones, the zircon is quite widely used in its three varieties: orange, blue, and colourless. The orange variety is called jacinth and was used to a great extent in classical antiquity. The blue variety is called starlite or Siam zircon, while the third type is called Ceylon or Matara diamond.

Among the semiprecious stones used in jewelry are amethyst, garnet, aquamarine, amber, jade, turquoise, opal, lapis lazuli, and malachite. Matrix jewelry is cut from a stone such as opal or turquoise and the surrounding natural material, or matrix.

Varieties of pearls

The pearl is one of the oldest gems known. Its colour varies according to the waters from which it comes. Pearls from the Persian Gulf are usually cream-coloured; those from Australia are white with greenish or bluish shades; golden-brown pearls come from the Gulf of Panama; those from Mexico are black or reddish brown; pink pearls are from Sri Lanka; and those from Japan are cream-coloured or white with greenish tones. The main characteristic of the pearl is its iridescence. Baroque pearls are those with defects in their outer layer. In modern times baroque pearls are rounded off artificially but, in the 16th and 17th centuries, their irregular form was exploited in jewelry by using them to make up parts of animals or other figures. After huge quantities of cultivated pearls invaded the world market, interest in natural pearls underwent a considerable decrease.

In addition to pearl, a number of other organic materials, including amber, coral, ivory, and jet, are considered gems.

Amber is a fossil resin, usually yellowish brown, but on occasion deep brown to red, green, or blue. It is an amorphous hydrocarbon and may contain particles of various foreign materials, trapped insects, and air bubbles. Its lustre is greasy to resinous. The most noted occurrence of amber is along the shores of the Baltic Sea, where pieces have been washed up by wave action. Other important occurrences are along the coast of Sicily, in Romania, and in Myanmar near Myitkyinā.

Coral is the skeletal material of calcium carbonate built up by small animals that live in colonies in the sea. This material is usually branchlike and occurs in a variety of colours, of which the most sought after are rose red to red. The best coral comes from the Mediterranean Sea, particularly off the coasts of Algeria and Tunisia. A black horny coral growth, probably conchiolin, which hardens on exposure to air, has been obtained off the islands of Hawaii. Coral is carved into art objects and cut as beads, cameos, and other ornaments.

The use of ivory for ornamental purposes dates to prehistory. The term should be restricted to the material derived from the tusks of certain animals—namely, the elephant, hippopotamus, warthog, walrus, sperm whale, narwhal, and the extinct mammoth (fossil ivory). The pale cream colour of new ivory darkens with age to yellow. All types are brittle and will not peel as do the plastics used to simulate them.

Jet is a dense variety of lignite formed by the submersion of driftwood in the mud of the seafloor. It has been recovered since Roman times from the shales near Whitby in northeastern England. It takes a high polish and was once popular as mourning and ecclesiastical jewelry but has been superseded by black onyx, black tourmaline, and plastics. Because it is actually a variety of coal, it will burn.

Gem engraving, setting, and cutting. The most ancient technique of stone engraving, intaglio-incised carving, was probably first used to produce seals. The art is believed to have originated in southern Mesopotamia and was highly developed by the 4th millennium BC. During the Hellenistic Age (*c.* 323–30 BC) intaglio surface engraving gave rise to the idea of carving stones in relief, exploiting the different coloured layers of certain minerals to create contrasting figures (cameo): the background was cut down to the lower level, of a different colour or shade, in order to make the subject stand out chromatically. The stones that have properties suited for this purpose are sardonyx, agate, and onyx.

Intaglio carving

The cameo is usually one of the components for necklaces, bracelets, and rings or is included in medallions with a jeweled frame. The art of cameo in jewelry was most highly developed during three periods: the late republican to early imperial period in Rome, the Renaissance, and the Neoclassical period in the 18th century.

The evolution of techniques of setting has followed that of stonecutting. The insertion of gems in jewelry can be done in various ways. The setting can have a round, square, oval, or rectangular collet (rim); in periods in which gems were mounted in their own irregular shapes, the collet followed this form. Usually, on the inside of the collet a short distance from the edge, there is a protrusion on which the stone rests. The edge is pounded down around the gem to ensure its stability. In coronet settings the form may be conical or pyramidal, solid or pierced. The edge is first shaped into a row of teeth, which are later hammered down onto the gem in order to hold it in place. Until fairly recently, nearly all gems were mounted on a metal base; and transparent stones, according to their colour, were placed on a gold or silver base to increase the amount of light reflected. As new cuts were developed for stones, setting techniques also progressed, especially for those jewels in which important stones like diamonds, emeralds, and rubies form the main theme. The tendency was to leave the stones as visible as possible (especially in rivière necklaces and bracelets made only of diamonds) by mounting them with a very small ring of white gold or platinum fitted closely against the back of the stone. Three claws, attached to this ring, hold the stone in place.

Pearls, like some coloured stones, in ancient classical times were pierced with a drill, the hole going half or all the way through according to whether the pearls were to be strung on a necklace or fastened onto a jewel.

Until the 15th century, stones were only polished or the part to be left visible was rounded into a dome shape called cabochon. The cutting known as faceting gradually developed from the first attempts in the 15th century, probably in France and the Netherlands. During the 16th

Gem cutting

century the simple rose cut began to be used, after which there were no new developments until 1640, when, under the patronage of Jules Cardinal Mazarin, the first brilliant cut was carried out (also called the Mazarin cut). Toward the end of that century, a Venitian succeeded in obtaining the triple brilliant cut, which is still used. The numerous cuts used for diamonds today are usually applied to other precious and semiprecious transparent stones as well. For emeralds, rubies, and other coloured stones the square or rectangular cut with a stepped bulb or the cabochon cut are usually used.

The history of jewelry design

The possibility of tracing jewelry's historic itinerary derives primarily from the custom, beginning with the most remote civilizations, of burying the dead with their richest garments and ornaments. Plastic and pictorial iconography—painting, sculpture, mosaic—also offer abundant testimony to the jewelry worn in various eras.

Prehistoric era

It is probable that prehistoric humans thought of decorating the body before they thought of making use of anything that could suggest clothing. Before precious metals were discovered, people who lived along the seashore decorated themselves with a great variety of shells, fishbones, fish teeth, and coloured pebbles. People who lived inland used as ornaments materials from the animals they had killed for food: reindeer antlers, mammoth tusks, and all kinds of animal bones. After they had been transformed from their natural state into various elaborate forms, these materials, together with animal skins and bird feathers, provided sufficient decoration.

This era was followed by one that saw a transition from a nomadic life to a settled social order and the subsequent birth of the most ancient civilizations. Most peoples settled along the banks of large rivers, which facilitated the development of agriculture and animal husbandry. Indirectly, this also led to the discovery of virginal alluvial deposits of minerals, first among which were gold and precious stones.

Over the years the limited jewelry forms of prehistoric times multiplied until they included ornaments for every part of the body. For the head there were crowns, diadems, tiaras, hairpins, combs, earrings, nose rings, lip rings, and earplugs. For the neck and torso there were necklaces, fibulae (the ancient safety pin), brooches, pectorals (breastplates), stomachers, belts, and watch fobs. For the arms and hands armlets, bracelets, and rings were fashioned. For the thighs, legs, and feet craftsmen designed thigh bracelets, ankle bracelets, toe rings, and shoe buckles.

MIDDLE EASTERN AND WESTERN ANTIQUITY

Sumerian. The most ancient examples of jewelry are probably those found in Queen Pu-abi's tomb at Ur in Sumeria (now called Tall al-Muqayyar), dating from the 3rd millennium BC. In the crypt the upper part of the queen's body was covered with a sort of robe made of gold, silver, lapis lazuli, carnelian, agate, and chalcedony beads, the lower edge decorated with a fringed border made of small gold, carnelian, and lapis lazuli cylinders. Near her right arm were three long gold pins with lapis lazuli heads, three amulets in the shape of fish—two made of gold and one of lapis lazuli—and a fourth amulet of gold with the figures of two seated gazelles. On the queen's head were three diadems, each smaller than the one below it, fastened to a wide gold band: the first, which came down to cover the forehead, was formed of large interlocking rings, while the second and third were made of realistically designed poplar and willow leaves (Figure 45). Above the diadems were gold flowers, on drooping stems, the petals of which had blue and white decorations. On the back of the headdress was a Spanish-type comb, with teeth decorated with golden flowers. Huge golden earrings, in the shape of linked, tapered, semitubular circles, completed the decoration of the head. On the neck was a necklace with three rows of semiprecious stones interrupted in the middle by an openwork flower in a gold circle. Many rings were worn on the fingers. There were large quantities of other jewels—among them wrist and arm bracelets and

Figure 45: Sumerian gold and faience diadems from Queen Pu-abi's tomb, Ur, *c.* 2500 BC. In the British Museum.
By courtesy of the Trustees of the British Museum

pectorals—belonging to the handmaidens, dignitaries, and even the horses that formed part of the funeral train. As was the custom, the queen's attendants had killed themselves in the crypt after the burial ceremony.

As this description suggests, Sumerian jewelry forms, much more numerous than those of modern jewelry, represent almost every kind developed during the course of history. Nearly all technical processes also were known: welding, alloys, filigree, stonecutting, and even enameling. Sources of inspiration, aside from geometry (disks, circles, cylinders, spheres), were the animal and vegetable world; and expressive forms were based on an essential realism enriched by a moderate use of colour.

The Tutankhamen treasure

Egyptian. The sensational discovery of the tomb of the pharaoh Tutankhamen (18th dynasty; 1539–1292 BC) revealed the fabulous treasures that accompanied an Egyptian sovereign, both during his lifetime and after his death, as well as the high degree of mastery attained by Egyptian goldsmiths. This treasure is now housed in the Egyptian Museum in Cairo and represents the biggest collection of gold and jewelry in the world. The pharaoh's innermost coffin was made entirely of gold, and the mummy was covered with a huge quantity of jewels. More jewels were found in cases and boxes in the other rooms of the tomb. The diadems, necklaces, pectorals, amulets, pendants, bracelets, earrings, and rings are of superb quality and of a high degree of refinement that has rarely been surpassed or even equaled in the history of jewelry.

The ornaments in Tutankhamen's tomb are typical of all Egyptian jewelry (Figure 46, right). The perpetuation of iconographic and chromatic principles gave the jewelry of ancient Egypt—which long remained uncontaminated in spite of contact with other civilizations—a magnificent, solid homogeneity, infused and enriched by magical religious beliefs. Ornamentation is composed largely of symbols that have a precise name and meaning, with a form of expression that is closely linked to the symbology of hieroglyphic writing. The scarab, lotus flower, Isis knot, Horus eye, falcon, serpent, vulture, and sphinx are all motif symbols tied up with such religious cults as the cult of the pharaohs and the gods and the cult of the dead. In Egyptian jewelry the use of gold is predominant, and it is generally complemented by the use of the three colours of carnelian, turquoise, and lapis lazuli or of vitreous pastes imitating them. Although there was a set, fairly limited repertoire of decorative motifs in all Egyptian jewelry, the artist-craftsmen created a wide variety of compositions, based mainly on strict symmetry or, in the jewelry made of beads, on the rhythmic repetition of shapes and colours.

Forms of Egyptian jewelry

The concept of symmetry was utilized on the small pectoral or pendant (3.3 × 2.4 inches, or 8.4 × 6.1 centimetres) that belonged to Sesostris III in the 12th dynasty (1938–1756 BC); the superbly rhythmic composition is framed by an architectonic design obtained by leaving open

all of the nonfigurative part (Figure 46, left). The jewel is coloured with carnelian, turquoise, and lapis lazuli inlays, while the function of the gold separating these materials is limited to creating the design. The victorious pharaoh is represented by two lions with the plumed heads of falcons in a symmetric position in the act of trampling conquered Nubians and Libyans. Over the scene is the protective vulture of Upper Egypt with wings outspread (Egyptian Museum). These memorial or dedicatory pendants, as well as other small jewels such as earrings, bracelets, and rings, consist exclusively of symbols.

Necklace beads—generally made of gold, stones, or glazed ceramic—are cylindrical, spherical, or in the shape of spindles or disks and are nearly always used in alternating colours and forms in many rows. The necklaces have two distinct main forms. One, called menat, was the exclusive attribute of divinity and was therefore worn only by the pharaohs. Tutankhamen's menat is a long necklace composed of many rows of beads in different shapes and colours, with a pendant and with a decorated fastening that hung down behind the shoulders. The other, much more widely used throughout the whole period, was the *usekh,* which, like the vulture-shaped necklace from the tomb of Tutankhamen, also has many rows and a semicircular form.

Of the many diadems made by Egyptian artist-craftsmen, one of the earliest was discovered in a tomb dating from the 4th dynasty (*c.* 2575–*c.* 2465 BC). It consists of a gold band supported by another band made of copper, to which three decorative designs are applied. In the centre is a disk worked with embossing in the form of four lotus buds arranged radially. On the sides are two papyrus flowers linked horizontally at the base by a disk with a carnelian, while the upper line of the flowers comes together to create a kind of nest in which two long-beaked ibis crouch. The floral and animal symbology is carried out with a style that interprets and characterizes the theme.

Among the treasures discovered in the tomb of Queen Ashhotep (18th dynasty) is a typical Egyptian bracelet. It is rigid and can be opened by means of a hinge. The front part is decorated with a vulture, whose outspread wings cover the front half of the bracelet. The whole figure of the bird is inlaid with lapis lazuli, carnelian, and vitreous paste.

Foreign influence

A first sign of outside influence occurs in the 18th dynasty and consists of earrings, which are imported jewels, unknown in classical Egyptian production. Another evidence of the influence of foreign styles in some of the jewelry of the 18th dynasty is a headdress (Figure 47) that covered nearly all of the hair, made of a network of rosette-shaped gold disks forming a real fabric (New York City, Metropolitan Museum of Art). Foreign influence increased to an ever greater extent during the last dynasties and with the arrival of the Greeks. Like all other forms of artistic expression, in spite of three centuries of Ptolemaic dynasty (up through 30 BC), the great artistic tradition of Egyptian jewelry slowly died out, and the introduction first of Hellenism and then of the Romans led to the definitive decline of the most monumental cultural and artistic structure known throughout all history.

Aegean. The Bronze Age civilization that flourished on the Mediterranean island of Crete is known as the Minoan. Because Crete lay near the coasts of Asia, Africa, and the Greek continent and because it was the seat of prosperous ancient civilizations and a necessary point of passage along important sea-trading routes, the Minoan civilization developed a level of wealth which, beginning about 2000 BC, stimulated intense goldworking activities of high aesthetic value. From Crete this art spread out to the Cyclades, Peloponnesus, Mycenae, and other Greek island and mainland centres. Stimulated by Minoan influ-

ence, Mycenaean art flourished from the 16th to the 14th century, gradually declining at the beginning of the 1st millennium BC.

Among the techniques used in Minoan-Mycenaean goldworking were granulation and filigree, but the most widely used was the cutting and stamping of gold sheet into beads and other designs to form necklaces and diadems, as well as to decorate clothing. The kings from Period I of Mycenaean civilization (*c.* 1580–1500 BC), discovered in their burial places, wore masks of gold sheet, and scattered over their clothing were dozens of stamped gold disks. The disks reveal the rich variety of decorative motifs used by the Mycenaeans: round, rectangular, ribbon-shaped—including combinations of volutes, flowers, stylized polyps and butterflies, rosettes, birds, and sphinxes.

A pendant from a Minoan tomb at Mallia, Crete (Archaeological Museum, Iráklion, Greece), is one of the most perfect masterpieces of jewelry that has come down to us from the 17th century BC (Figure 48). The Sun's disk is covered with granulation and is held up by two bees, forming the central part of the composition. Ring bezels (tops of the rings), with relief engravings of highly animated pastoral scenes, cults, hunting, and war, are also fine. Like those of the other jewelry forms, the ornamental motifs of the necklaces are varied, including dates, pomegranates, half-moons facing each other, lotus flowers, and a hand squeezing a woman's breast. During the late Mycenaean period, earrings appeared in the shape of the head of a bull, an animal frequently represented in early gold plate.

In addition to goldworking, Minoan-Mycenaean craftsmen also excelled at engraving gemstones for seals and rings.

Phoenician. Phoenicia, a centre for both the production and exportation of jewelry, was not a source of great originality. It is to the trading done by this people throughout the Mediterranean, however, that we owe knowledge of the products of the most highly developed civilizations in the most remote lands—northern Africa, Sardinia, Spain, and Italy. The period in the 8th and 7th centuries BC, during which Scythian-Iranian Oriental objects with their animalistic motifs were spread and consequently imitated throughout the Mediterranean countries, especially in Greece and Italy, is called the Orientalizing period.

Orientalizing period

Etruscan. In Etruria, to a much greater extent than elsewhere, the stimulus provided by the jewelry imported by the Phoenicians led to emulation that soon had imposing results. Alongside imported objects and mechanically repeated Oriental motifs, original forms, techniques, and styles developed that were the result of Etruscan taste. There was an entirely new concept, in which the goals of magnificence, impressive size, and a great wealth of decoration led to some of the most outstanding achievements in the history of jewelry. Technical virtuosity exploited all the resources available to filigree and above all to granulation, carried out with gold alone without chromatic inlaying.

Fibulae began to be made in forms other than the single Oriental leech, or boat, shape: with a dragon bow, lozenge-shaped, with a long foot. Like such ornaments as pendants and the heads of pins, fibulae were often decorated with gold dust, in which opaque granulated figures—ibexes, chimeras, sphinxes, winged lions, centaurs, horsemen, and warriors, nearly all of Oriental derivation—stand out against the smooth surface of the gold. One notable example is the fibula from the lictor's tomb in Vetulonia (Figure 49).

SCALA—Art Resource

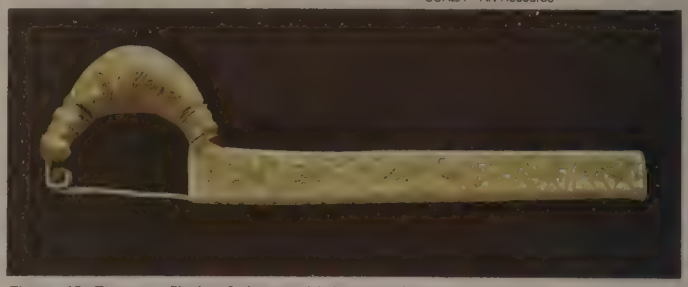

Figure 49: Etruscan fibula of sheet gold decorated with animals made by the granulation technique, from the lictor's tomb, Vetulonia, 7th century BC. In the Archaeological Museum, Florence.

The most elaborate, complicated examples of Orientalizing Etruscan jewelry consist of very large brooches with fully sculptured decoration applied to a combined tubular and plate structure. The minutely designed granulated figures of sphinxes, winged lions, chimeras, winged griffons, and human heads—set in series in alternating rows—form a plastic fabric, the details of which are of astonishing technical ability, while at the same time they suggest the evocative, mysterious animalistic symbolism of western Asian civilizations.

In the period that followed the Orientalized one, Etruscan jewelry revealed Ionic influence (6th–5th century BC). The most beautiful examples are necklaces made of many flexible chains that cross each other and bear different rows of embossed pendants in the shape of harpies, mermaids, Gorgons, and Sileni, interspersed with others such as pomegranates, acorns, lotus flowers, and palms. These show the clear influence, especially in the modeling of the pendant heads, of the Greek severe period, an influence that spread throughout the entire Etruscan territory, from Spina on the Adriatic coast of Italy to southern Italy. Even clearer evidence of the acceptance of imported forms is provided by a new shape, the bulla, a pear-shaped vessel used to hold perfume. Its surface was decorated with embossed and engraved symbolic figures.

Greek. Because gold was not readily available, jewelry was relatively rare in Archaic (*c.* 750–*c.* 500 BC) and Classical (*c.* 500–*c.* 323 BC) Greece. Examples do exist, however, and certain generalizations can be made. In the 7th and 6th centuries BC the jewelry produced in Attica and the Peloponnese shows evidence of strong Oriental stylistic influence, the same influence that in Etruscan territory turned up in a much more magnificent form. In the 5th century BC the Ionic style became predominant, taking the place of the showy Oriental style. War scenes and animals of Oriental origin disappeared, for example, from the wide oval ring bezels and were replaced exclusively by the human figure. These included naked riders on galloping horses; seated and standing maidens, depicted both with clothes and naked; and deities and mythological figures. This extremely refined repertoire in reality was more closely related to sculpture and to classic ideals of beauty than to decoration. Indeed, in its long evolution, Greek jewelry has the predominant character of sculpture in miniature and represents isolated figures or religious, mythological, or heroic scenes.

Greek expansion into Anatolia to the east, southern Italy to the west, and the Balkan Peninsula to the north

Hellenistic jewelry

resulted in the Hellenization of this entire area. Under the reign of Alexander the Great, a magnificent era for jewelry began. Hellenistic jewelry, much more so than painting and sculpture, underwent flourishing development in the art centres of the different regions under Greek rule. In the 3rd and 2nd centuries BC, the technical ability of Hellenistic goldsmiths reached the highest levels ever attained. A style both sumptuous and full of plastic vigour was created, in which meticulous arrangement of the decorative motifs resulted in the contrast and harmony, clarity and unity, rhythms and cadences that make some of these jewels complete works of art. The very fine technique and virtuosity in miniature is reflected in the creation of the first cameos and in disk earrings bearing pendants, often of minute proportions. A real masterpiece is an earring with a winged figure of a woman driving a two-horse chariot (Museum of Fine Arts, Boston). The precision of its tiny details, the severity of style with which it is modeled, and the rhythmic dynamism of the figures make this earring a microscopic monument of sculpture (Figure 50, right).

Also worthy of high consideration are the magnificent diadems that came into wide use as a result of the Persian conquests made by Alexander the Great. One type is a rigid elliptical shape with a Hercules knot in the centre and pendants hanging down over the forehead. (The Hercules knot was the most famous one used in ancient times, as it was considered a magic knot and, in jewels, took on the significance of an amulet. It also was used on bracelets, belts, and rings during this period.) Another type, decorated with jewellike enameled flowers (Figure 50, bottom), demonstrates the increasing use of colour during the Hellenistic Age.

One type of necklace that was commonly worn at this time was made of gold pieces, often hollow or filled with resin, that were fashioned into the shape of acorns, amphorae, and rosettes that sometimes alternated with stones or vitreous paste. In the 3rd century BC the bracelet in the shape of a serpent originated and remained popular through the Roman period (Figure 50, left). The serpent motif also was used for rings.

Roman. In ancient Rome, jewelry was used to an extent never seen before and not to be seen again until the Renaissance. Imperial Rome became a centre for goldsmiths' workshops. Together with the precious stones and metals that were brought to the city came lapidaries and goldsmiths from Greece and the Oriental provinces. The gold ring, which under the republic had been a sign of distinction worn by ambassadors, noblemen, and senators, gradually began to appear on the fingers of persons of lower social rank until it became common even among

soldiers. The great patrician families in Rome and the provinces possessed not only jewels but also magnificent gold and silver household furnishings, as shown by the objects found in Pompeii (Figure 51) and nearby Boscoreale (Louvre).

Stylistic characteristics of Roman jewelry

From the standpoint of style, Roman jewelry in its earlier phases derived from both Hellenistic and Etruscan jewelry. Later it acquired distinctive features of its own, introducing new decorative themes and attaching greater importance to sheer volume (such as massive rings), in keeping with the rather pompous rhetorical spirit displayed at that point in cultural history.

The motif of a serpent coiled in a double spiral, copied from Hellenistic models, was frequently used for bracelets, rings, arm bands, and earrings. The Romans also used Greek geometric and botanical motifs, palmettos, fleeting dogs, acanthus leaves, spirals, ovoli, and bead sequences. From Etruscan gold jewelry the Romans took the strong plasticity of the bulla, which they transferred to necklace pendants sparely decorated with filigree or combined in completely smooth hemispheres in bracelets, headdresses, and earrings.

In Pompeii and Rome, jewelry began to take on Italian characteristics. New decorative motifs of a magical nature began to appear, such as the half-moon and the wheel with four spokes. In addition, as Roman jewelry freed itself of Hellenistic and Etruscan influences, greater use was made of coloured stones—topazes, emeralds, rubies, sapphires, and pearls. A strong preference was shown for engraved gems, so much so that they were considered collectors' items by wealthy people, including Caesar himself. The stones were set in bezels or supported by pins that passed through them. New techniques that came into use included *opus interassile,* with which a flat or curved metal surface was decorated with tiny pierced motifs, and niello, a method of enameling used primarily to decorate rings and brooches.

Many pendants were used in the earrings: from a ring a series of pieces hung down with square bezels or bands of small bullas alternating with stones, which in turn supported pendants in different shapes. There was an extremely varied production of gold mesh and chains, often containing inserted bezels set with stones or half pearls, while others had ivy or laurel leaves attached to them. Although pendants were not used on necklaces in the beginning, later examples have pendants in the form of embossed medallions. Precious stones, vitreous pastes, and cameos with golden frames also served as pendants for necklaces. Toward the end of the 3rd century AD, necklaces often bore medallions or gold coins with portraits of the emperors.

MIDDLE AGES

Byzantine. Ancient Rome, which had brought its civilization to practically all of the world that was known at that time, began to lose its vitality in the early Christian era; by the end of the 4th century AD, its civilization was in full decline. Although its power was gone, Roman culture was indelibly imprinted on Western civilization. The Roman Empire had embraced Christianity, although in reality it was the papacy that had embraced the Roman Empire. The intention of the Byzantine court (at Constantinople, the new seat of imperial power) to maintain Roman supremacy in the field of the arts was forced to give way to a style more closely related to that of the Middle East. Partly for religious reasons, this style soon developed a new spirit and its own distinctive characteristics. The wave of iconoclasm—the controversy in the 8th and 9th centuries about the depiction of images in religious art—gave the decoration of jewelry, too, a basically ornamental nature, in which the techniques used to the greatest extent were filigree, *opus interassile,* and enameling, as well as the copious application of precious stones and pearls. Very complex decorations and arabesques were obtained with filigree, while enameling was favoured for representations of flowers and birds. Typically Byzantine were the half-moon-shaped earrings that were in wide use up through the 12th century. There are examples with pierced decoration, with filigree basketwork, and with the figures of enameled birds facing each other on a golden half-moon (Figure 52). The court jewels, if credit can be given to the figures shown in the mosaics in the church of San Vitale at Ravenna, must have been of astonishing splendour. Although the mosaics give only a sketchy idea, on the figures of Justinian, Theodora, and their retinue, precious ornaments can be distinguished that were of ceremonial magnificence suited to their rank.

Iconoclasm

For all practical purposes, Constantinople's artistic activities came to an end when it was conquered and looted during the Fourth Crusade in 1204.

Islāmic. After the Arab conquest of Iran brought it into the Islāmic community of peoples, rings, pendants, earrings, and necklaces of gold continued to be worn, and the Iranian tradition of animal art persisted, modified to some extent in order to conform to the canons of Islām, which forbade the making of images. A 12th-century gold pendant in the form of a lion is a highly schematic rendering of this animal; it is decorated with granulation. Other techniques were filigree, encrustation with precious and semiprecious stones, and the use of niello. From the 14th century onward, manuscript illustrations give some idea of the kind of jewelry worn by Persians. In Mongol and Timurid times, jeweled coiffures for women and diademed headdresses for men seem to have been fashionable in court circles. Under the Ṣafavid rulers, jewelry became more sumptuous and elaborate. In the 19th century, native traditions were corrupted by European influence, often with an eye toward European consumption. Traditional designs, however, have persisted in Zīnjanāb and among the Kurdish mountaineers of northwest Iran. Silver decorated with twisted wire arranged in scrolls is a feature of the former. The Kurdish goldsmiths also work in silver, which they decorate with chased or repoussé

designs, sometimes reminiscent of motifs found on Sāsānian metalwork.

Jewelry worn by men and women in Turkey during the Ottoman period was probably influenced by the fashions current in Iran. Objects of adornment were jeweled turban aigrettes, rings, earrings, necklaces, and armlets. A technique popular in Turkey from the 16th century onward was the encrusting of jade and other hard stones with jewels attached to the surface by delicate floral scrolls in gold. Unfortunately, not many surviving pieces are earlier than the 19th century, when native tradition had been stifled by a taste for Rococo jewelry.

North African designs

In North Africa an independent tradition has been maintained by the Berber and Arab tribes. In design the jewelry of southern Morocco shows curious analogies to Byzantine jewelry—heavy silver plaques decorated with niello or cabochons that serve as diadems or headbands. In other parts of Morocco and in Algeria and Tunisia, popular forms of jewelry are headbands, breast ornaments, brooches, pendants, and a characteristic triangular-shaped shawl pin.

Teutonic. While in the Byzantine area classic forms of expression were being wiped out by the development of a skillful class of artisans who impressed their entirely ornamental taste on jewelry produced solely for decorative purposes, in the rest of Romanized Europe a huge, complex movement of peoples was taking place. Bringing their tradition of polychrome decoration with them, these peoples swarmed over the old declining Greek-Roman artistic civilization. Goths, Vandals, Huns, Franks, and Lombards emigrated, extending their conquests into central, northern, and southern Europe beginning in the 4th century AD, and they remained there until the 9th century. In accordance with an ancient definition, they were called barbarians—that is, not Christians but foreigners. They also were considered barbarians because they were thought to have destroyed the classical art of the Roman world.

Throughout all the provinces of the Roman empire, these Teutonic tribes produced gold ware that shared a common, well-defined style moderated according to the tastes of the particular regions in which they settled. The blend of Teutonic and Iranian, Scythian, Sarmatian, or Celtic styles produced ornaments that bore little resemblance to those of the great classic tradition. Precious ornamentation, which represented the main artistic ambition of these nomadic peoples, was achieved with faience (decoration made of opaque coloured glazes), jewels, and enamels. Dominant also was braiding, which was done with strips of embossing, with bands of stones or enamel set in bezels, and also with filigree.

Teutonic fibulae

There was a highly varied production of fibulae. One of the most impressive for its size (14 inches) is the one in the shape of a bird found in Petroasa, Rom. (National Museum of History, Bucharest, Rom.), whose body is covered with sockets of different sizes and shapes in which stones and enamel were meant to be set (Figure 53). The most widely used type of fibula was the so-called buckler variety, with a fan head, arched bridge, and flat or molded foot, with pierced work in various shapes. Equally common were disk fibulae, either flat or with concentric embossing, while S-shaped fibulae and belt buckles were rarer.

Rigid necklaces, made up of several circles with much decoration, were typical. The most magnificent examples are those from the 6th century from Alleberg and Färjestaden, Sweden (Museum of National Antiquities, Stockholm). A ring with zoomorphic braiding (Poldi Pezzoli Museum, Milan) was found in the same region. This technique was most widely used in the Celtic and northern Germanic regions of Europe, while in the British Isles, to judge from the magnificent jewels in the Sutton Hoo burial-ship treasure (British Museum, London), it was the technique of enameling that reached extremely high levels. In northern Europe and Scandinavia the main goldworking techniques were filigree, embossing, and turning on a lathe.

As time passed, the different products of barbaric goldworking art took on a more definite stylistic identification according to the various races and locations.

Western European. The widespread adoption of Christian burial rites put an end to the custom of burying the dead with all their jewelry. Thus, beginning with the 8th century, almost the only important gold products handed down to modern times were those preserved in abbey and cathedral treasures or by imperial and royal courts; among these gold products are very few pieces of jewelry. As the graphic and plastic arts gradually developed, however, they documented the jewelry in use at the time. According to these sources, little jewelry was worn in the Romanesque period (*c.* 950–*c.* 1150).

Figure 53: *Early medieval jewelry.*

In the 11th century, monastic workshops for the service of the church began to decline, disappearing one after another to be replaced by secular workshops. Goldworking activities in western Europe gradually freed themselves from the centralizing patronage of the church in order to serve the numerous courts and noble families, and in the 12th century the first goldsmiths' guilds were organized.

Formation of goldsmiths' guilds

One of the most widely used ornaments in medieval Europe was the ring. To it was attributed ever more symbolic and religious value, as well as ever greater importance as a talisman, good omen, and sign of office; and, as always, it served as a seal.

Another widely used ornament was the brooch. Most popular was the medallion type, which might be round, star-shaped, or pentagonal, while the diamond shape was less common. Ring brooches, which were open in the centre, also were popular. They took many forms, including round, pentagonal, and star-, heart-, or wheel-shaped. One outstanding bejeweled and enameled example—the Founder's Jewel bequeathed by William of Wykeham to New College, University of Oxford, in 1404—is in the shape of the letter M (Figure 54, top). The arches formed by the letter resemble Gothic windows, reflecting the importance of architectural elements in all forms of art

Figure 54: *Gothic jewelry.*

at this time. Standing in the windows are the expertly modeled figures of the Virgin Mary and the Angel of the Annunciation, and the whole is surmounted by a crown.

Flamboyant Gothic style

Another fine example that typifies the plastic decorative repertory of the flamboyant Gothic style is a silver belt buckle from Sweden (Historical Museum, Stockholm). Modeled in high relief on the buckle plate is a gentleman on horseback approaching a lady followed by his servant (Figure 54, bottom). The three-lobed buckle ring is modeled in a complex design that includes a seated person and a man kneeling in front of him (*c.* 1340).

RENAISSANCE TO MODERN

15th and 16th centuries. The "rebirth" of Classicism, which combined all artistic expression in a single orderly, rational approach, found a fertile creative field in gold jewelry. During the Renaissance the jeweler's art reached truly high levels—particularly in Italy in the grand duchy of Tuscany. Eighteen centuries after the great flowering of Hellenistic jewelry, Italian Renaissance jewelry once again achieved an expressive form worthy of comparison with the figurative arts. There was, in fact, no sharp division between the two. Nearly all the most famous artists responsible for the Renaissance artistic revival—Lorenzo Ghiberti, Filippo Brunelleschi, Antonio and Piero Pollaiuolo, and Sandro Botticelli—served apprenticeships in the goldsmiths' workshops, where gentlemen went to order medallions for their hats and where ladies went to have their jewels set.

Because of their elaborate workmanship, which meant that their artistic value was far greater than the intrinsic value of their materials, many pieces of jewelry have been handed down to modern times in public and private collections. Even more extensive evidence, however, is provided by paintings from this period that show the jewelry worn by both men and women. From portraits by Botticelli and Piero di Cosimo, one can see, for example, that as early as the second half of the 15th century the elaborate decoration of women's hair with precious materials had become a real art, in which goldsmiths and craftsmen carefully worked out every line of the often extremely complicated ornamental design that had to harmonize with the movement of braids or unbound hair (Figure 55).

Increase in the use of jewelry during the Renaissance

During the Renaissance there was an enormous increase in the use of jewelry throughout Europe. The courts of England, France, and Spain, the French duchy of Burgundy, and the Italian duchy of Tuscany indulged in extravagant contests, trying to outdo each other in the display of gold, gems, and pearls, a phenomenon that for centuries had not occurred on such a large scale. The nobility and the rich middle class followed this fashion, and even the youngest scions were covered with jewels, as evidenced by the portrait of the Medici princess by Il Bronzino, as well as many others. Francis I of France surrounded himself with famous artists like Benvenuto Cellini and Leonardo da Vinci. In Paris, artists such as Jean Duvet, Étienne Delaune, and the Fleming Abraham de Bruyn were the outstanding creators of designs for jewelry. Hans Holbein the Younger was the individual who was most responsible for the introduction of Renaissance jewelry from the Continent into England, where he found fertile ground, thanks to Henry VIII's great passion for jewels—a passion surpassed only by that of Elizabeth I (Figure 56). Henry possessed more than one magnificent parure, or set of matching jewelry, designed for him by Holbein, as well as several hundred rings.

As Holbein's portrait of Henry VIII suggests, the custom of wearing bejeweled clothing, which had begun gradually in the 14th century, flourished in the Renaissance (Figure 19). Even hat brims were decorated, with designs in pearls as well as with pendants of great value.

In Holbein's portrait there is also a magnificent example of a popular necklace of the period. It consisted of wide gold bands decorated with embossing that formed medallions, in the center of which were mounted large stones. From the necklace hung a pendant. Only rarely were women content to limit themselves to a single necklace, usually wearing a choker-type necklace made of pearls, with or without a pendant, together with a longer second necklace made of gold, with or without the inclusion of

Carlo Bevilacqua—SCALA from Art Resource

gems. A third necklace was often hooked to the clothing, on the shoulders, and formed a double loop, being lifted up in the centre and fastened to the bodice with a jeweled pin.

The precious ornament on which the artist-jewelers lavished all their creativity and technical ability was the pendant. At first this consisted of a decorative medallion enclosing a cameo with figures and subjects of classic derivation, such as busts of women and pagan deities. These figures were later enriched with inserts of gold, enamel, and gems, which enhanced the polychrome effect (Figure 57, right). Still later, the figures were freely modeled in brilliant polychromy with a great variety of subjects—animals, Tritons, mermaids, ships, sea monsters, and symbolic figures, sometimes in elaborate tableaux—fashioned in complicated openwork compositions comprising several linked pieces, in which the irregular shape of a large baroque pearl was often used for the body of an animal or a centaur's torso (Figure 57, left).

Throughout Europe the ring enjoyed wide popularity in an unlimited variety of types, including those with a bezel that could be opened and used as a container for relics, symbols, or—as romantic tradition has it—poison.

17th century. Toward the end of the 16th century, the Renaissance style blended gradually into the manifestations of the Baroque period, which arose at different times in different countries. This gradual change in the style of jewelry was conditioned mainly by two factors. The first was of a technical nature and concerned improvements in the cutting of precious stones, while the second consisted of a great vogue for the cultivation of flowers. Floral and vegetable decoration therefore became the most fashionable theme for jewelry designers, and its popularity spread throughout Europe. The ornamental motifs of knots, ribbons, and Rococo scrolls also saw a considerable development. There was a corresponding decrease in the amount of figurative decoration, which finally completely disappeared. At first these ornamental forms were carried out in openwork gold jewelry, the majority of which was coloured with enamel; later diamonds and other precious stones, whose popularity rose dramatically with the improvement in faceting techniques, became the real protagonists in the composition of jewelry (Figure 58).

Period of Louis XIV

During the 17th century the number of pieces of jewelry worn decreased, as did the fashion for male adornment. The last monarch to make heavy use of jewels was Louis XIV, and the word heavy is used here in a literal sense, the great weight consisting mainly of gems with which the monarch covered himself for official ceremonies. He had his own personal jeweler, Gilles Légaré, who was a guest in the Louvre palace. He was not the only sovereign, however, who enjoyed showing off his jewels nor was Versailles the only court in Europe to follow the king's example. Those of London, Madrid, and Munich were

not far behind. The precious ornaments worn by women started on the hat, on the side of which at least one striking aigrette (spray of gems) was fastened. Then came two or three heavy necklaces, each of which might have a pendant, then a belt that followed the pointed shape of the bodice. Other jewels were inserted along the armholes, shoulders, and wrists, and at least four rings were worn on the hands. Often the heavy fabrics used for the clothing were embroidered with gold thread. It was during this period that a spectacular form of jewelry was created in Spain, which in a more subdued form spread throughout Europe: the stomacher brooch, which covered a woman's entire bodice, from neckline to waist. With its heavily bejeweled composition of scrolls, leaves, and pendants on a gold framework that followed the curves of the body, even extending under the armpits, this jewel usually contained no fewer than 50 precious stones of different sizes. A famous example is the one in emeralds from the treasure of the Virgin of Pilar, now displayed in the Victoria and Albert Museum, London (Figure 59).

Use of Brazilian diamonds

18th century. About 1725, Brazilian diamonds in large numbers were imported into Europe, and, during the course of the century, this stone became so popular that imitations were produced. The jewelry of this period seems to have been created to glorify and exploit the cutting of diamonds and other precious stones. The dense forms of Baroque jewelry were replaced by an entirely different conception, in which the design was to appear in gems alone, while the metal setting was concealed to the greatest extent possible. The greater lightness that resulted was increased by the large number of empty spaces in the composition as well as by its lack of symmetry in many cases. Wide choker necklaces with pendants were popular, and the stomacher brooch remained in style but in a lighter, airier form. The jeweled stems of the aigrette were often made so that they could sway back and forth in order to show off the sparkle of the diamonds that covered them. The brooch in the shape of a bouquet of flowers, comprising a variety of gems, became fashionable. As in the 17th century, both men and women wore jeweled buckles on their shoes.

A piece of jewelry that was widely used for daytime wear during this century was the chatelaine, on which, together with the watchcase, goldsmiths lavished some of their most highly refined work (Figure 60). The chatelaine was a pendant made of jointed, embossed gold components of different shapes and sizes, with scenes and designs in elaborate frames. It was fastened by means of a hook to the belt or waistcoat pocket, and from its protruding points hung decorative chains of various lengths, on which men fastened their watches, the keys for winding them, and other accessories. Women used the chatelaine to carry keys, scissors, and other more or less useful objects.

Classical ideals and Josiah Wedgwood

During the last 30 years of the 18th century, the great sensation caused by the archaeological discoveries in Pompeii and Herculaneum caused art forms to turn toward classical ideals of harmony and brought about a decisive change in European tastes and decorative forms. Curved lines no longer appeared in the ornamental repertoire, the new Neoclassical style being characterized by greater simplicity, together with severity of composition. Jewelry forms, too, were influenced by decorative motifs based on Greek and Roman models, and the cameo became fashionable once again.

An English pottery manufacturer, Josiah Wedgwood, made a big contribution to the popularization of the new jewelry forms. An expert technician, he produced reproductions of classic cameos, calling upon sculptors like John Flaxman to work with him on the execution of oval, round, and octagonal plaques with figures done in relief in a white paste on a light blue, green, black, or pink background. These plaques, framed in gold, were used for all sorts of jewelry—medallions, pins, pieces of diadems, belts, bracelets, and rings.

19th century. The Industrial Revolution destroyed forever the ancient role of jewelry as a symbol of social rank. The social evolution created a market for a vast quantity of jewelry at prices the middle class could afford; and

so jewelry, too, succumbed to the machine. Hundreds of different components for ornaments were produced by machines, an electric gold-plating technique was invented, metal alloys were used in place of gold and silver, and the production of imitation stones increased in both quantity and quality. Despite the growing dominance of the machine, however, the goldsmiths' technical ability remained at a high level.

The jewelry produced in the 19th century is characterized by a stylistic eclecticism that takes its inspiration from all past styles—Gothic, Renaissance, Greek, Etruscan and Roman, Rococo, Naturalistic, Moorish, and Indian, all tinged with the Sir Walter Scott–Lord Byron Romanticism of the period. The futility of transferring forms of artistic expression from an era in which they were the result of organic aesthetic development and of adopting them for objects that reflect only a gesture of romantic admiration is evident in the painting by Jacques-Louis David (Louvre, Paris) immortalizing Napoleon's coronation ceremony in 1804 (Figure 61). The painting provides documentation on the precious ornaments worn by the ladies who were present. In their jewelry, the conventional, rhetorical Empire style appears as a strict, uninspired interpretation of classical motifs, a far cry from the exquisite Neoclassicism of the 18th century.

Artistic commercial jewelry firms

Besides mass production, the 19th century saw the establishment of large artistic commercial firms that produced high-quality jewelry suited to the requirements of the prosperous new bourgeois class. While always satisfying very high standards in regard to technique and materials, these firms tended, from the aesthetic point of view, to reflect the tastes of a bourgeois clientele, which are usually quite traditional.

The oldest of the firms was the one founded by Peter Carl Fabergé in St. Petersburg in 1870, which took over from the firm his father had started in 1842. Fabergé attained great renown at the Universal Exposition in Paris in 1900, where for the first time he put on display all the imperial Easter eggs that he had created, together with a selection of other "luxurious objects." Fabergé used a greater variety of precious and semiprecious stones than almost any other jeweler in history. He had a strong preference for the Louis XVI style but also made numerous objects in the Italian Renaissance, Rococo, and medieval styles, as well as in the so-called old Russian style, which is a mixture of Byzantine and Baroque elements. Decoration with enameling, too, was one of the main specialties of the Fabergé firm.

In Paris in 1898 Alfred Cartier and his son Louis founded a jewelry firm of great refinement. The firm was distinguished for a production characterized by very fine settings, largely of platinum, which were designed so that only the precious stones, always selected from the very purest, were visible (Figure 62, right). At the beginning of the 20th century, Cartier was the most famous jeweler in the world, supplying jewels to the king of Portugal, the duke of Saxe-Coburg-Gotha, the grand dukes and princes of Russia, the Prince of Wales, and other notables.

In the United States in 1851 Charles Lewis Tiffany (father of Louis Comfort Tiffany, one of the most original of the Art Nouveau artist-craftsmen) began producing silverware according to English "sterling" standards in New York City. In 1886 he introduced the Tiffany setting, a special type of fork for the setting of diamonds. Among his clients was President Abraham Lincoln.

Other high-quality jewelry firms founded in the 19th century were Van Cleef & Arpels in Paris (Figure 62, left), Bulgari in Rome, Asprey & Company in London, Black, Starr & Frost in New York City, and Patek Philippe in Geneva.

Art Nouveau

The development of the movement called Art Nouveau at the end of the 19th century represented a reaction against the imitation of ancient styles and the emphasis given, in the creation of jewelry, to precious stones. The material used for Art Nouveau jewelry was prized not for

its intrinsic value but for its ability to render a design or to carry out chromatic effects. The new jewelry was made from any material that would best express the new symbolic or decorative ideas. Vegetable and animal components, together with the feminine figure, formed the basis for compositions made of flowing lines of rich plastic and chromatic effect and antistructural, dynamic design on a high artistic level.

In Paris, through the works he presented at the Salon du Champ de Mars in 1895, René Lalique (1860–1945) achieved a position of European renown and importance. Lalique personified the Art Nouveau jeweler-artist, his works providing evidence of such highly personal taste that they can be compared to Renaissance jewels. They lean toward a symbolism carried out by the use of milky or watery blue-green colours; of stones such as the opal; of disquieting animals such as the snake, the owl, the octopus, and the bat; and of feminine figures, usually enigmatic, mysterious, and dreamy. Enamel, ivory, vitreous paste, and engraved glass were often used by Lalique to obtain pictorial and plastic effects in his jewels (Figure 63, left).

Unlike Lalique, the jewelers Georges Fouquet (1858–1929) and Henri Vever (1854–1942) expressed themselves through more synthetic geometric forms. The pendant representing a butterfly by Fouquet and the bracelet and ring for the actress Sarah Bernhardt (both in the Périnet Collection, Paris) show a carefully thought-out stylization (Figure 63, right).

The Czechoslovak graphic designer Alphonse Mucha (1860–1939), who worked in Paris, created a number of jewelry designs, transferring his brilliant talent as an illustrator to precious stones and metals.

In the United States the floral style in jewelry found one of its most highly personal interpreters in Louis Comfort Tiffany (1848–1933), one of the greatest of all American designers. In the creation of jewelry he expressed himself at first by transferring to Art Nouveau forms the colourful Oriental and Byzantine style that so fascinated him. Later he adopted Lalique's French Symbolism, on which he set his own stylistic mark. His development of the richly coloured, iridescent Favrile glass created an international sensation.

20th century. The Art Nouveau movement came to an end at the beginning of World War I. The years that followed the war's end seethed with new excitement. In this new phase, the stylistic trends—particularly the nonfigurative—that began to emerge in the most advanced jewelry creations were closely linked to those of painting and sculpture. Cubism, Futurism, the abstractionism of Piet Mondrian and other artists of the de Stijl group, Paul Klee's paintings, and above all the Bauhaus school (which aimed at integrating artistic disciplines with one another and with industrial techniques) provided a basis for the new forms used in avant-garde jewelry.

Compositions were based mainly on the interplay of geometric forms. Like Art Nouveau jewelry, creations of the Art Deco movement (named for the art displayed at the 1925 Paris exposition) used materials suitable for expressing the new stylistic language. Preference was given to the smooth, polished, satined surfaces of precious metals or even of steel. Diamonds and other precious stones were used sparingly, functioning largely as chromatic accents. In the same piece of jewelry, coral could be combined with diamonds, regardless of the great difference in intrinsic value, because their sole purpose was to satisfy the aesthetic requirements of the nonfigurative styles. Art Deco

During this period there were outstanding artist-jewelers such as Raymond Templier, Jean Fouquet, and René Robert in France, H.G. Murphy in England, and Wiwen Nilsson in Sweden.

Later, artists of great international renown devoted some of their creative efforts to the art of jewelry. Some—such as Georges Braque, Jean Cocteau, Max Ernst, Jean Arp, Man Ray, Salvador Dali, Yves Tanguy, and Jean Dubuffet—designed jewelry, while others—including Pablo Picasso,

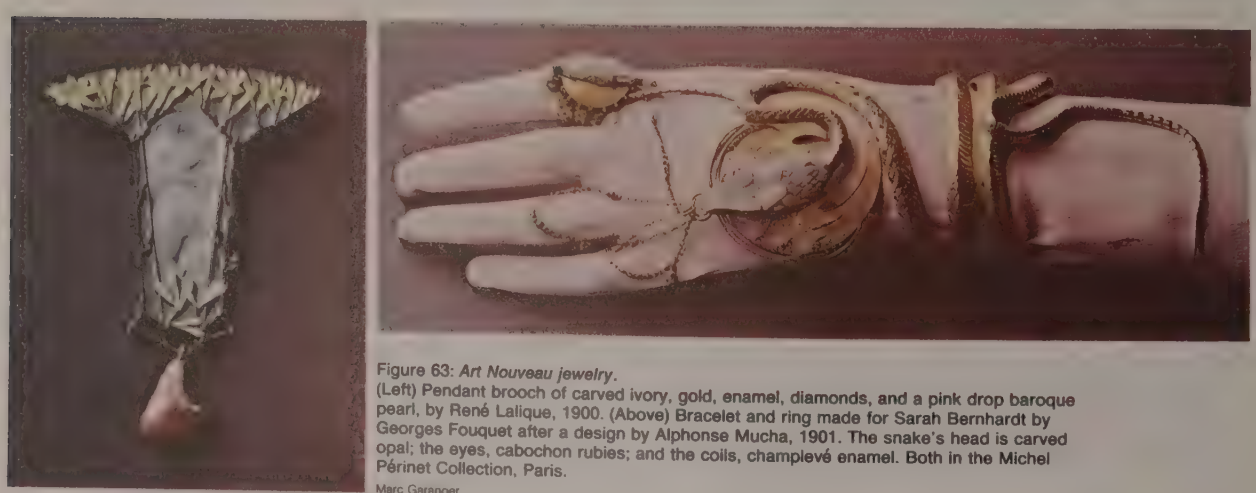

Figure 63: *Art Nouveau jewelry.*

(Above) Bracelet and ring made for Sarah Bernhardt by Georges Fouquet after a design by Alphonse Mucha, 1901. The snake's head is carved opal; the eyes, cabochon rubies; and the coils, champlevé enamel. Both in the Michel Périnet Collection, Paris.
Marc Garanger

Alexander Calder, Alberto Giacometti, Gio Pomodoro—designed and made jewels.

One of the most recent developments in modern mass-produced jewelry is the use of plastic. This material, as well as providing colour, can have mineral fragments or dust embedded in it or can be used in combination with more or less valuable metals, producing pieces of jewelry whose composition may call for considerable effort and which may be of much interest.

NON-WESTERN CULTURES

Jewelry to adorn the costume rather than the body

East Asian. *Chinese.* Much of Chinese jewelry, both of recent and early date, displays the familiar manipulative skill of the Chinese craftsmen; yet the work of the goldsmith or lapidary applied to personal ornament does not represent so distinct a branch of craft as it does in the West and is accorded no special attention by the native connoisseurs and writers on the arts. Most of the jewelry is designed to adorn the costume rather than the person, and much of it has a fulsome and insubstantial quality that is not immediately pleasing to Western eyes. Necklaces, bracelets, and earrings are comparatively rare, headdresses and elaborate hairpins being the more common forms attached to the person (Figure 64). In the traditional costume of recent times, ornate hooks and buckles were used to attach girdles, and women wore strings of beads, often multiple and variously spaced, with decorative plaques and other larger ornaments interspersed. The beads might be attached to the neck, head, or waist, and their purpose was to dignify the whole figure, rather than to display the fine quality of a curiously wrought gem. In any case, the splendour of the stuff of the costume, with richly woven or embroidered ornament, provided the distinctions of rank and wealth, and jewelry was often dispensed with altogether. The long sleeves and high collar of the garment left little of the person exposed for ornament set against the skin, in the manner favoured in the West.

In the time of the Shang dynasty, in the last centuries of the 2nd millennium BC, bone and ivory hairpins with ends carved in the form of birds or abstract figures were a popular adornment. The many finely wrought, small jade plaques of the period, depicting animals in profile, are in many cases clearly intended for sewing to the costume. The earliest evidence of gold ornaments belongs to the time about 400 BC, though these are harness mounts, or weapon parts, rather than jewelry in the usual sense. The latter is better represented by the belt hooks (said to have been adopted from the nomads of inner Asia) that were probably worn by both men and women. They were mostly made of bronze, with fine cast ornaments usually of abstracted dragon and bird heads. These belt hooks were inlaid with gold or silver foil, polished fragments of turquoise, or more rarely with jade or glass; sometimes they were gilded.

Toward the end of the Han dynasty, probably not before the later 2nd century AD, the art of granulation was communicated to China from the Hellenized region of the Black Sea coast. Granulation can be traced in China until about the 10th century AD, its discontinuation in the East curiously coinciding with the loss of the technique in the West. Granulation was combined with filigree; and hairpins, combs, earrings, and costume plaques survive in some quantity, particularly from the richly furnished tombs of the T'ang dynasty (AD 618–907). There are plaques with birds and flowers delineated by soldered wire, inlaid with turquoise, on a ground of fine granulation that appears like a dust of gold.

The employment of the repoussé technique in gold and silver, particularly on the heads of combs, can be attributed to the T'ang period but became more common in the Sung dynasty (AD 960–1279). Meanwhile, hairpins of filigree, with heads shaped as butterflies or flowers, sometimes with pearls or small jade additions, continued the age-old fashion. A scented hairpin takes the place of the scarf or ring of European romance. They were called *pu yao* ("shaking while walking") and were loosely made so as to sway when the wearer moved. Gilded bronze and silver were the principal materials. There are accounts of elaborate headdresses, some no doubt of the kind representing a complete phoenix such as are to be seen on clay tomb statuettes of the T'ang period, but no surviving examples of these can be attributed with certainty to the Sung period. Jade ornaments during this period were still attached to the costume.

Ming dynasty jewelry

Jewelry survives in greater quantity from the Ming dynasty (AD 1368–1644) and gives an impression of greater taste for elaborate figural and floral designs in high repoussé relief and for the effect of semiprecious stones. The latter were prized for their colour rather than their luminosity or rarity. They are never elaborately faceted, being merely ground flat and beveled at the edge for the most part and are set nearly always *en cabochon,* with barely a preliminary polishing, sometimes even retaining the irregularities of the pebble. The stones are invariably semiprecious or even commonplace: amethyst, agate, chalcedony, pink and other quartzes, and, of course, jade. Until modern times, this last has been the most admired of the stones, especially the white variety, which was used for spacers and linking pieces in the silk and beaded hangings of elaborate costumes. The plaques of silver repoussé with flowers and scenes of people were probably used only by men as belt ornaments. Apart from the signet ring, the use of which may not go back beyond Ming times, the male could affect jewelry only in his accoutrement.

Magatama, inrō, and netsuke

Japanese. From as early as 1000 BC until the 6th century AD, Japanese jewelry primarily consisted of comma-shaped objects—not usually more than an inch in length—carved initially of green jade and eventually of glass. Called *magatama,* these beads or pendants were sometimes pierced to be strung in a necklace. The symbolic meaning of the *magatama,* which were often placed in tombs, can only be guessed at. Similar beads also were popular in Korea from the 3rd to the 6th century AD.

In historical times, traditional Japanese costume, male and female, has never allowed the use of ornaments of precious metal or stone, so that nothing in the history of Japanese craft and taste corresponds to the jeweler's work of the West. Hairpins with elaborate heads were increasingly used in the Tokugawa (Edo) period (1603–1868) by women of the geisha and courtesan classes but not by women of other classes. In the same period men were permitted the ostentation of the *inrō,* a small tiered box for tobacco, medicines, confections, and the like, which might be beautifully painted in lacquer and inlaid with mother-of-pearl or precious metal, often in strikingly naturalistic designs. The ivory girdle toggle called netsuke, always delicately and often intriguingly carved, was the only other personal ornament that usage allowed.

Indian. The Indian subcontinent consists of the Republic of India, Pakistan, Bangladesh, and Sri Lanka, but at various times in history its domain has spread to include the neighbouring countries of Nepal, Myanmar, and parts of Afghanistan as well. The area's earliest known urban civilization is called the Indus, or (after an important archaeological site) the Harappān, civilization. It is dated roughly from 2300 to 1750 BC. From this period can be attributed a graceful bronze statue representing a naked dancer. The dancer's hair is braided and decorated, and she wears a necklace with three pendants. Her left arm is fully covered by armlets, and her right arm has an armlet at the elbow and another one near the wrist. This absolutely outstanding specimen provides documentation for the early establishment of the Indian practice of wearing multiple bangle bracelets. Although archaeological evidence of rings, bracelets, and other types of jewelry have been found, no other actual documentation of the way the pieces were worn is available for this period.

Bronze, stone, and ivory sculptures have been discovered dating from the 2nd century BC onward. These include two female figures found in Bhārhut. The statues are lavishly adorned with jewelry: hair ornaments, earrings, necklaces with round and cylindrical beads, chains, belts, coiled ankle bracelets, arm bracelets, and arm rings. Apart from these jewels, the figures wear only a small cloth on their heads. This abundance of jewelry, complemented by little more than veils and scarves, is typical as far as Indian ceramics, painting, and sculpture are concerned. Female figures in Indian art of all periods are almost always depicted wearing huge quantities of jewelry in place of real garments; indeed, the jewels can be thought of as serving as a type of clothing.

The use of jewelry as clothing

The first date for which there is extensive documentation on jewels is the 4th–5th century AD. This information is provided by Buddhist statues and the cycles of wall paintings in the Ajantā caves. Although certainly not the only source for such works, the Ajantā site is one of the most extensive and best preserved. The great variety of types of jewelry represented and the dominance of polychromy indicates the high degree of development attained by the art of jewelry making.

The lavish use of polychrome jewelry was possible because of the ancient practice of pearl diving and because of the wealth and variety of deposits of precious and semiprecious stones to be found in India and the neighbouring countries of Sri Lanka, Thailand, and Myanmar. This situation of plenty, in combination with a favourable climate, helped goldsmiths and jewelers to proliferate and spread, albeit to the detriment of a truly high-class artistry. Although the jewelers were exceptionally skilled craftsmen, they do not seem to have been stylistic innovators. There are no records of particularly gifted artist-jewelers; the only names that have come down through the ages are those of large numbers of patterns.

In the Indus areas and in those under their influence, the setting, polishing, and piercing of precious and semiprecious stones underwent precocious evolution. Stone-cutting, however, was accepted only recently; in the past it was considered preferable not to decrease the size of the stone. In general, there was a preference for a many-hued rich effect that was less a form of artistic self-expression than a display of showy glitter aimed at astonishing the onlooker.

Kinds of Indian jewelry

During the Mughal Empire (1526–1761), rich rajas adorned themselves with jewels—on their turbans, on their ears, around their necks, inserted in their nostrils and even between their teeth. The precious objects worn by women were even more numerous. By this time Indian jewelry had acquired special meanings and nomenclature in connection with a variety of religious beliefs; thus every object had its own specific name, indicating its role and form. For the head alone there were golden wreaths, large brooches, braids made from three bands of gold leaves with a star in the middle set with gems, braids to be placed along the part in the hair, lotus leaves made of gold sheet to be worn at the nape of the neck with bunches of gold flowers next to them, and tiaras in complicated shapes complete with many tinkling pendants. There were similarly large numbers of individually named ornaments for the forehead, the ears, the nose, the neck, the upper part of the arm, the wrist, the fingers, the ankles, and the toes. A variety of forms were used for the earrings, in which pearls, filigree, gems, and coral appeared in floral compositions based on the contrast between the different colours. Some Indian women embedded a jewel in the forehead or pierced the nose in order to wear a jewel in the left nostril. Necklaces were sometimes so long that they came below the navel, and different names were given to those made only of pearls and those of gold. The former also were distinguished according to the number of strings, of which there could be as many as several dozen. Some necklaces were made of a combination of precious stones and pearls, while others were made of amulets in various shapes. A very early type of Hindu amulet called a *nauratan* was made of a gold plaque with nine precious stones fastened above it. A series of *nauratans* could be used to form a necklace. Jeweled belts followed the shape of the body and often had extra pieces that reached up to the neck or down to the bracelets worn around the thigh. Ankle bracelets were often linked by tiny decorative chains running down the instep to the rings on the toes.

Jewelry continues to play an important role in modern Indian dress, but frankly the items produced today do not compare with those of the past. On the contrary, the modern ornaments, though lavishly produced, are of only limited artistic interest.

Southeast Asian. There is a long gold-working tradition among the peoples of Southeast Asia, whose jewelry shows evidence of Tibetan, Chinese, and Indian stylistic influence. The areas in which personal ornamentation with precious objects underwent the greatest development were Myanmar, Cambodia, Laos, and Vietnam. Myanmar jewels are outstanding for the beauty of their designs and for the technical accomplishment of their workmanship. Typical of them is the conical headdress, reflecting the traditional architectural form of the stupa (Buddhist shrine), and the bejeweled, rigid shoulder decorations with a raised line similar to that of pagoda roofs, worn by dancers in addition to arm and ankle bracelets, belts, and brooches made of gold and coloured stones. Although it has its own distinct characteristics, Myanmar jewelry was heavily influenced by Indian styles, especially in regard to a taste for great abundance; thus, each single jewel, rather than standing out, blends into the overall effect.

Myanmar, Cambodia, Laos, and Vietnam

Cambodia, Laos, and Vietnam were subject to greater Chinese influence because of their geographic position. In these territories, too, the principal documentation for the period when precious ornamentation experienced its most flourishing development is to be found in Buddhist sculpture. The outstanding forms of expression in the art of jewelry were thus linked to religious rites, contributing to the glorification of the figures worshiped by the cult.

Scythian. It is to the Scythians, a seminomadic people

Figure 65: Scythian gold bracelet from the Ziwiye treasure, Persia, 7th century BC. In the Guennol Collection, New York City.

By courtesy of the Guennol Collection, photograph, Metropolitan Museum of Art, New York City

from the Eurasian steppes who moved out from southern Russia into the territory between the Don and the Danube and then into Mesopotamia, that we owe a type of gold production, which, on the basis of its themes, is classified today as animal-style. During the early period (5th–4th century BC), this style appeared on shaped, pierced plaques made of gold and silver, which showed running or fighting animals (reindeer, lions, tigers, horses) alone or in pairs facing each other, embossed with powerful plasticity and free interpretation of the forms. The animal-style had a strong influence in western Asia during the 7th century BC. Such ornaments as necklaces, bracelets, pectorals, diadems, and earrings making up the Ziwiye treasure (discovered in Iran near the border between Kurdistan and Azerbaijan) provide evidence of this Asiatic phase of Scythian gold-working art (Figure 65). The ornaments are characterized by highly expressive animal forms. This Central Asian Scythian-Iranian style passed by way of Phoenician trading in the 8th century BC into the Mediterranean and into Western jewelry.

African. Personal decoration in African cultures usually consists of modest though showy material. The works with a relatively high degree of development come from those areas in which the influence of more advanced Mediterranean and Oriental cultures led to activities of some significance in the field of jewelry. Silver was the metal most commonly worked, especially in the northern coastal territories, and the forms used for ornaments were derived mainly from the art of Islām. Decoration that rarely surpassed the level of craftsmanship appears on objects such as bracelets, necklaces, rings, brooches, earrings, and belt buckles, and the techniques were usually limited to embossing, filigree, and the insertion of coins or semiprecious stones that had simply been polished.

Regions such as Ethiopia, the Sudan, and the Bantu territory, partly because of their Egyptian-Nubian and Arabian origins and partly because they were the centres of a flourishing gold trade, developed a gold-working activity of fairly high quality, which was devoted mainly to the production of objects for the courts and for religious ceremonial use. These regions also were devoted to the production of personal ornaments such as embossed plaques, rings, necklaces, and tiaras.

Jewelry of the Ashanti culture of Ghana

The same observations hold true for the Ashanti culture in Ghana, from which there is a large collection of gold jewelry in the British Museum in London. The local chieftain of each Ashanti tribe had a private workshop for gold jewelry in his small court. In the 18th and 19th centuries the most magnificent court was that of the Asantehene (king of the united Ashanti state) in Kumasi, the Ashanti capital on the Gold Coast. A widely used object was the emblem of the "bearer of souls," a decorated disk that, together with other insignia, was borne by the king's pages (Figure 66). On the back of the disk was a little tube through which a gold wire or cord was run. The decoration of these disks consisted of a mixture of separate and varied embossed radial or spiral motifs, derived in an unorthodox manner from classical art. The mysterious presence of these ornamental motifs in Ashanti jewelry can be explained only by the sporadic appearance of European goldsmiths in that area, probably during medieval times. Rigid necklaces also were in use, as were rings, which instead of the bezel had fully sculptured figures of animals.

In the past the sandy dunes of Senegal provided alluvial soil from which the natives obtained much gold. There, as in other parts of Africa, the metal that was not exported was used to make ornaments for the tribal chieftains. These were very elaborate objects with complicated decorative motifs worked in embossing or punched freehand. The objects were characterized by the repetition of the designs used and by protruding hemispheres that were smooth or decorated, according to their size.

In these regions, where the making of jewelry was directly dependent on what was obtained from local deposits, gold was the only material used. Usually the type of decoration, taken from imported models or introduced directly by European goldsmiths, persisted as a repertoire was acquired, with a tendency toward ever greater repetition. In other words, rather than an art form dominated by genuine native expression, this production has no relation to the local culture.

American Indian. *Central and South American: pre-Columbian.* The ancient peoples located in the region near the northern Andes (including Peru, Colombia, Ecuador, and Venezuela) achieved a high degree of artistic evolution. Gold mines were abundant in this area, and the goldsmith's art was highly developed. The gold was worked not only by itself but also in alloys with copper, silver, and other metals. The oldest surviving products, attributed to the Chavín culture in Peru, date to as early as 1000 BC. The subsequent Moche culture (*c.* 400 BC–AD 500) and the Nazca culture (both in Peru) also produced gold ornaments of high technical quality.

Andes region

By the time Spanish explorers reached the region in the 16th century, they were astounded at the wealth and magnificence of the then-flourishing Inca empire. Unfortunately, the Spanish melted down most of the gold objects they found. Many examples remain, however—most of them discovered in graves. Study of these materials

has revealed that there were several different centres of production and local styles.

The richest gold and mineral deposits, which are still productive, were those in Colombia. It is not possible to establish definite dates for jewelry from Colombia and Ecuador, but an approximate chronology indicates the San Augustin zone as the oldest, followed by Chitcha. In the latter area, the "Quimbaya treasure" and objects from the upper Cauca River (Calima style) represent jewelry of the greatest importance and magnificence. Other significant centres in Colombia include the Muisca region; Calima, famous for its breastplates, tiaras, and brooches; and Tolima. Although not strictly part of the Andes region, the Coclé region in Panama was strongly influenced by the Quimbaya style. It is particularly known for its striking gold pieces set with precious stones, including emeralds, quartzes, jaspers, opals, agates, and green serpentines.

In the civilizations of the Andes, gold was lavishly used on clothes. About 13,000 pieces of gold were found sewn into a single poncho from Chimú, Peru. On certain occasions the priests wore tunics made entirely of braided gold sheet applied to the cloth. One of the commonest ornaments worn by important personages and warriors was the *nariguera*, a gold ornament that was hooked to the nostrils and might be in the shape of a simple ring, a laminated disk, or an upside-down fan decorated with pierced work. The elite also wore pendants depicting gods or animals.

The most adorned and decorated section of the body was the head. Although gold and other precious metals were components of these ornaments, feathers and other brightly coloured materials were the most important features—the more elaborate the trimmings, the higher the social rank and class of the wearer. Examples of such headdresses can be seen in the great sculptured reliefs found in some ceremonial places.

Rings were rather rare, but there are necklaces with a seashell motif in different shapes arranged one after the other and necklaces with other stylized zoomorphic forms that are all alike. One of the most outstanding of these necklaces is from Chimú (May 21, 1968, Christie sale). It is composed of a row of gold beads to which are attached eight similar figures of a deity in a ritual pose (1100–1200).

Meso-America

Outstanding artistic development during the pre-Columbian era also took place in the region known as Meso-America (including about half of present-day Mexico, all of Guatemala and Belize, and parts of Honduras and El Salvador). When the Spanish reached this area in the early 1500s, they found magnificent monuments, which had been partly invaded and destroyed by woods and brush, but extremely few and scattered people. The reasons that induced the early inhabitants to abandon those places are still unknown, and many potentially illuminating written documents were destroyed by the Spanish. Nevertheless, historical research has determined that the region was inhabitated from about 1500 BC first by the Olmec, then by the Maya, Mixtec, and other groups, and eventually—and until the time of the Spanish conquest—by the Aztec.

Only a few examples of jewelry from this region survive, namely some finely carved jades, which apparently were considered more precious than gold. Works of the goldsmiths' art are rare, although of a high quality. A few examples owned by the Museum of the American Indian in New York City are noteworthy, especially a wonderful Mixtec necklace that proves the high degree of technical skill attained. The necklace is composed of 40 small segments in the form of a tortoise's back, and from each segment hang three drop pendants.

Mixtec graves have yielded outstanding examples of objects such as gold pendants (Figure 67), jewels combined with turquoise mosaic, and quartz ear spools. The few examples that remain from the Aztec period suggest the stylistic influence of the Andes region. Of the decorative animal motifs, the most frequent is the serpent; of the ornamental motifs, the spheroid, disk, and sphere. Probably because the Meso-American area was poor in gold, objects made of this material date from about 1,000 years after those from the Andes (*c.* 14th century BC).

It is thought that ornamental objects in precious materials from the pre-Columbian civilizations, especially the older ones, had some religious function in addition to being used in burial rites. Stylistically, pre-Columbian objects show an unusual amount of charming expressiveness. Symbolic concepts were transferred from stone and pottery to gold through transfigurations that enhanced the plasticity of the forms, displaying at the same time an awareness of structure and of compositional rhythms that forms the main appeal of these objects.

Religious function of pre-Columbian jewelry

North American. The diverse forms taken by personal ornamentation are related to the type of life led by the numerous ethnic and tribal groups scattered throughout the vast American territory. The most highly developed tribes were those whose social organization permitted them to settle in one place for long periods of time, with the consequent evolution of religious and artistic activities.

On the basis of archaeological finds, North American Indian territory was divided culturally into the following broad areas: the eastern forests, which includes the Great Lakes region and Florida, east of the Mississippi; the Great Plains, including the central part of the continent between the eastern forests and the Rocky Mountains; the Southwest, which corresponds to what are now the states of Arizona, New Mexico, southeastern Utah, and southern Colorado; the northwestern coast, from the bay of Yakutat in Alaska to the mouth of the Columbia River; and California, in the area included between the northwestern coast and the southwestern cultures.

The Great Plains and California produced no jewelry, the former area because its slow artistic evolution involved primarily the decoration of clothing with leather and beadwork, and the latter because its tribes were economically at the preagricultural level and therefore lacking in forms of artistic expression apart from those associated with perishable materials. Judged on the basis of the archaeological data that has come to light so far, the highest artistry was achieved by the southwestern cultures, followed by those of the eastern forests and of the northwest.

Personal ornamentation in all the native cultures of North America shows no connection with the pre-Columbian cultures of Central and South America. One of the most striking differences between the two is that in North America copper was much more frequently used than gold. In some parts of North America this metal may have been used before its use became known in the Western world, and at that distant time it was valued like gold.

As far back as the Archaic period, the practice of decorating shells with carving (Figure 68) or champlevé enamel work was widespread. Feathers and turquoise (used for mosaic) complete the list of precious materials available to the American Indians for personal ornamentation until the arrival of the white man.

Figure 68: Shell etched in the horned toad motif, from the Snaketown excavations, Arizona; Hohokam, AD 900–1150. In the Arizona State Museum, Tucson.

On the whole, in their limited diversity, forms of artistic expression became traditional for particular cultures and were perpetuated by them. Even today, attempts are still being made to keep them alive.

Indians of the Southwest

In the southwestern cultural area the first objects used for personal ornamentation go back to the first half of the 1st millennium AD and consist of bracelets made from a shell carved in the shape of a frog, exquisitely sculptured in miniature; zoomorphic subjects on auricular disks; rings with bird and snake motifs in pierced work; and other shell jewelry covered with turquoise mosaics.

The Pueblo and Navajo tribes, which were part of the southwestern cultural area, made beautiful necklaces and pendants from turquoise mosaics, shells, and coral. The Pueblo Bonito discoveries document this activity from pre-Columbian times. At the beginning of the second half of the 19th century, the Navajo learned to work silver from Mexican craftsmen and developed this skill with great ability, reworking motifs of Spanish American origin in their Indian traditional style.

In the Great Lakes region where the Woodland culture was located, archaeological research has demonstrated the presence of copper ornaments as early as the 5th millennium BC. These consist of necklace beads formed of thin, narrow metal strips and of sheet metal in the shape of fish. The Hopewell finds include bobbin-shaped copper earrings and engraved sheets of silver, dated between 200 BC and AD 400, together with ornaments that were sewn into clothing or inserted in headdresses. From the Mississippian Period there are pieces of embossed copper sheet and breastplates, disks, and plaques made of copper and shell with a wealth of engraved ornamental motifs, such as birds, Sun symbols, isolated heads, human skulls, eagles, rattlesnakes, hands with outspread fingers and an eye designed on the palm, crosses, and figures of warriors.

Beginning in the 17th century, the Seneca, Cayuga, Onondaga, and Iroquois tribes in the New York state region hammered, shaped, and cut European silver coins to be used for jewelry of all kinds. Also worthy of note among the Iroquois are bone combs with handles carved in zoomorphic shapes.

Indians of the northwest coast

In the culture of the Indians on the northwest coast, the influence of Arctic and even of Asiatic peoples can be observed. Persons of very high rank wore a characteristic type of headdress, which was made of wood, in a conical shape with wide brim, surmounted by sculptured human and animal figures. Another type was shaped like a crown or diadem with a rectangular plaque worked in relief placed in the middle of a leather forehead band from which ermine tails and bunches of sea-lion bristles stuck out. The sculpturing on these plaques is highly refined, and the rich shell inlay with which they are decorated makes them look like jewels. The engraving on combs is also outstanding.

The sculptural style peculiar to this culture is characterized by a conventional, formal naturalism that is extremely vigorous and dynamic. Often the same object combines parts that are fully sculptured with parts in low relief, and the depth of the carving may vary greatly.

Objects called copper coins, symbols of maximum power and wealth, were in the form of a shield made of copper sheet in a standardized shape (trapezoidal above and rectangular below). The upper half was taken up by a design such as a head worked in engraving or embossing.

During the 16th century, European conquest and rule of the American continent interrupted development of the arts among the natives, who were forced to live under conditions that were far from favourable to the continuation of traditional artistic activities. (G.Gr.)

BIBLIOGRAPHY

General works. Broad histories of Western dress and clothing accessories, spanning many centuries of development, are FRANÇOIS BOUCHER and YVONNE DESLANDRES, *20,000 Years of Fashion: The History of Costume and Personal Adornment*, new ed. (1987; also published as *A History of Costume in the West;* originally published in French, 1983); MILLIA DAVENPORT, *The Book of Costume*, 2 vol. (1948, reissued in 1 vol., 1976); JAMES LAVER and CHRISTINA PROBERT, *Costume and Fashion: A Concise History*, new ed. (1982); RICHARD CORSON, *Fashions in Makeup: From Ancient to Modern Times* (1972), and *Fashions in Hair: The First Five Thousand Years* (1969, reissued 1984); DOREEN YARWOOD, *European Costume: 4000 Years of Fashion* (1975, reprinted 1982), and *English Costume: From the Second Century B.C. to the Present Day*, 5th ed., rev. (1979); NANCY BRADFIELD, *Historical Costumes of England: From the Eleventh to the Twentieth Century*, 3rd ed., rev. (1970); ALFRED RUBENS, *A History of Jewish Costume*, new and enlarged ed. (1973, reissued 1981); and J. ANDERSON BLACK, MADGE GARLAND, and FRANCES KENNETT, *A History of Fashion*, rev. ed. (1980). More thematically oriented studies include MARGOT HAMILTON HILL and PETER A. BUCKNELL, *The Evolution of Fashion: Pattern and Cut from 1066 to 1930* (1967, reprinted 1987); ELIZABETH EWING, *Fur in Dress* (1981), and *Dress and Undress: A History of Women's Underwear* (1978, reprinted 1989); C. WILLETT CUNNINGTON and PHILLIS CUNNINGTON, *The History of Underclothes*, new rev. ed., by A.D. MANSFIELD and VALERIE MANSFIELD (1981); DIANA DE MARLY, *Working Dress: A History of Occupational Clothing* (1986), and *Fashion for Men: An Illustrated History* (1985); and PENELOPE BYRDE, *The Male Image: Men's Fashion in Britain, 1300–1970* (1979).

Most of the above cited works are well illustrated, but the following two are richly pictorial: DOREEN YARWOOD, *Costume of the Western World: Pictorial Guide and Glossary* (1980); and LUDMILA KYBALOVÁ, OLGA HERBENOVÁ, and MILENA LAMAROVÁ, *The Pictorial Encyclopedia of Fashion* (1968; originally published in German, 1968). Other works suitable for quick reference include DOREEN YARWOOD, *The Encyclopaedia of World Costume* (1978, reissued 1986); C. WILLETT CUNNINGTON, PHILLIS CUNNINGTON, and CHARLES BEARD, *A Dictionary of English Costume* (1968, reissued 1976); MARY PICKEN, *The Fashion Dictionary: Fabric, Sewing, and Apparel as Expressed in the Language of Fashion*, rev. and enlarged ed. (1973); and R. TURNER WILCOX, *The Dictionary of Costume* (1969, reissued 1989).

Ancient dress. Clothes of the early period of civilization are studied in MARY G. HOUSTON, *Ancient Egyptian, Mesopotamian & Persian Costume and Decoration*, 2nd ed. (1954, reprinted 1972), and *Ancient Greek, Roman, and Byzantine Costume & Decoration*, 2nd ed. (1947, reprinted 1966); THOMAS HOPE, *Costume of the Ancients*, new ed., enlarged; 2 vol. (1812, reissued in 1 vol. as *Costumes of the Greeks and Romans*, 1962); LILLIAN M. WILSON, *The Clothing of the Ancient Romans* (1938), and *The Roman Toga* (1924); HANS C. BROHOLM and MARGRETHE HALD, *Costumes of the Bronze Age in Denmark*, trans. from Danish (1940); and ERHARD KLEPPER, *Costume in Antiquity* (1964; originally published in German, 1963).

Medieval dress. Readable and well-illustrated accounts of the developments in Western fashion include STELLA MARY NEWTON, *Fashion in the Age of the Black Prince: A Study of the Years 1340–1365* (1980); MARY G. HOUSTON, *Medieval Costume in England & France: The 13th, and 14th, and 15th Centuries* (1939, reprinted 1965); and JOAN EVANS, *Dress in Mediaeval France* (1952). For non-European medieval dress, see DONALD CORDRY and DOROTHY CORDRY, *Mexican Indian Costumes* (1968, reprinted 1978); SIDNEY M. MEAD, *Traditional Maori Clothing: A Study of Technological and Functional Change* (1969); and TE RANGI HIROA (PETER H. BUCK), *Arts and Crafts of Hawaii* (1957, reissued 1987).

Modern Europe. Histories of fashion include studies of various countries and stylistic trends: see STELLA MARY NEWTON,

The Dress of the Venetians, 1495–1525 (1988); JOHN TELFER DUNBAR, *The Costume of Scotland* (1981); OLGA ŠROŇKOVÁ, *Fashions Through the Centuries: Renaissance, Baroque, and Rococo* (1959); DIANA DE MARLY, *Louis XIV & Versailles* (1987); ANNE BUCK, *Dress in Eighteenth-Century England* (1979), and *Victorian Costume: And Costume Accessories,* rev. 2nd ed. (1984); MARGARETE BRAUN-RONSDORF, *Mirror of Fashion: A History of European Costume, 1789–1929* (1964; originally published in German, 1963; also published as *The Wheel of Fashion: Costume Since the French Revolution, 1789–1929*); NANCY BRADFIELD, *Costume in Detail: Women's Dress, 1730–1930,* new ed. (1981); NORAH WAUGH, *Corsets and Crinolines* (1954, reissued 1987); MADGE GARLAND, *Fashion* (1962); DIANA DE MARLY, *The History of Haute Couture, 1850–1950* (1980); ELIZABETH EWING, *History of Twentieth Century Fashion,* rev. ed. (1986); and O. E. SCHOEFFLER and WILLIAM GALE, *Esquire's Encyclopedia of 20th Century Men's Fashions* (1973).

For insights into the work of fashion designers, see such surveys as MARTIN BATTERSBY, *Art Deco Fashion: French Designers 1908–1925* (1974, reprinted 1985); IRVING PENN and DIANA VREELAND, *Inventive Paris Clothes, 1909–1939: A Photographic Essay* (1977); and JOHN PEACOCK, *Fashion Sketchbook, 1920–1960* (1977, reissued 1984). See also such biographies and autobiographies as DIANA DE MARLY, *Worth: Father of Haute Couture,* 2nd ed. (1990); PALMER WHITE, *Poiret* (1973); ALFRED ALLAN LEWIS and CONSTANCE WOODWORTH, *Miss Elizabeth Arden* (1972); CHRISTIAN DIOR, *Christian Dior and I* (1957; originally published in French, 1956; also published as *Dior: The Autobiography of Christian Dior*); MARY QUANT, *Quant by Quant* (1966, reissued 1974); and ELSA SCHIAPARELLI, *Shocking Life* (1954).

American dress. Histories of American costume include DIANA DE MARLY, *Dress in North America: The New World, 1492–1800* (1990); ELISABETH MCCLELLAN, *Historic Dress in America, 1607–1800* (1904), and *Historic Dress in America, 1800–1870* (1910), reprinted together as *Historic Dress in America, 1607–1870,* 2 vol. (1990); ALICE EARLE, *Two Centuries of Costume in America, 1620–1820,* 2 vol. (1903, reprinted 1974); ESTELLE ANSLEY WORRELL, *Children's Costume in America, 1607–1910* (1980); and R. TURNER WILCOX, *Five Centuries of American Costume* (1963, reissued 1988).

Oriental dress. Eastern tradition is explored and illustrated in JACQUELINE AYER, *Oriental Costume* (1974); ALAN PRIEST, *Costumes from the Forbidden City* (1945, reissued 1974); SCHUYLER V.R. CAMMANN, *China's Dragon Robes* (1952); A.C. SCOTT, *Chinese Costume in Transition* (1958); SEIROKU NOMA, *Japanese Costume and Textile Arts* (1974; originally published in Japanese, 1965); HELEN BENTON MINNICH, *Japanese Costume and the Makers of Its Elegant Tradition* (1963); G.S. GHURYE, *Indian Costume,* 2nd ed. (1966); and S.N. DAR, *Costumes of India and Pakistan: A Historical and Cultural Study* (1969).

Nature and purpose of dress. Social and psychological aspects of dress and the place of fashion in human culture are the subject of many works representing various disciplines. See JOHN C. FLÜGEL, *The Psychology of Clothes* (1930, reissued 1976); JAMES LAVER, *Modesty in Dress: An Inquiry into the Fundamentals of Fashion* (1969); QUENTIN BELL, *On Human Finery,* 2nd ed., rev. and enlarged (1976); ANNE HOLLANDER, *Seeing Through Clothes* (1978, reissued 1988); ALISON LURIE, *The Language of Clothes* (1981); ELIZABETH WILSON, *Adorned in Dreams: Fashion and Modernity* (1985); and PATRICIA A. CUNNINGHAM and SUSAN VOSO LAB (eds.), *Dress and Popular Culture* (1991). (D.Y./D.J.A. de M.)

Jewelry. Broad surveys include J. ANDERSON BLACK, *A History of Jewels,* rev. ed. (1981; also published as *The Story of Jewelry*); GUIDO GREGORIETTI, *Jewelry Through the Ages* (1969; originally published in Italian, 1969); ERICH STEINGRÄBER, *Antique Jewelry: Its History in Europe from 800 to 1900* (1957); JOAN EVANS, *A History of Jewellery, 1100–1870,* 2nd ed., rev. (1970), and *Magical Jewels of the Middle Ages and the Renaissance, Particularly in England* (1922, reprinted 1976); ANNE WARD *et al.*, *The Ring: From Antiquity to the Twentieth Century* (1981; also published as *Rings Through the Ages*); ERNLE BRADFORD, *Four Centuries of European Jewellery* (1953, reissued 1967); FRITZ FALK, *European Jewellery: From Historism to Modern Style* (1985); and G. MOUREY and A. VALLANCE, *European Art Nouveau Jewelry* (1969).

Materials of the art are studied in C.H.V. SUTHERLAND, *Gold: Its Beauty, Power, and Allure,* 2nd rev. ed. (1969); ROBERT WEBSTER, *Gems, Their Sources, Descriptions, and Identification,* 4th ed., rev. by B.W. ANDERSON (1983); JOHN SINKANKAS, *Gemstones of North America,* 2 vol. (1959–76); and GRAHAM HUGHES, *The Art of Jewelry: A Survey of Craft and Creation* (1972, reissued 1984).

Particular styles and periods are discussed in CYRIL ALDRED, *Jewels of the Pharaohs: Egyptian Jewelry of the Dynastic Period* (1971); REYNOLD HIGGINS, *Greek and Roman Jewellery,* 2nd ed. (1980); JAMILA BRIJ BHUSHAN, *Indian Jewellery, Ornaments, and Decorative Designs,* 2nd rev. ed. (1964); RONALD JESSUP, *Anglo-Saxon Jewellery* (1950, reissued 1974); PRISCILLA E. MULLER, *Jewels in Spain, 1500–1800* (1972); MARGARET FLOWER, *Victorian Jewellery,* new and rev. ed. (1973); JOHN HAYCRAFT, *Finnish Jewellery and Silverware* (1962); and MARY L. DAVIS and GRETA PACK, *Mexican Jewelry* (1963, reprinted 1982).

Books devoted to individual practitioners or describing particular museum collections and exhibitions include A. KENNETH SNOWMAN, *The Art of Carl Fabergé,* 2nd ed. (1962, reissued 1972); HERBERT HOFFMANN and PATRICIA F. DAVIDSON, *Greek Gold: Jewelry from the Age of Alexander* (1965); CHRISTINE ALEXANDER, *Jewelry: The Art of the Goldsmith in Classical Times as Illustrated in the Museum Collection* (1928); EDWARD F. TWINING, *A History of the Crown Jewels of Europe* (1960); MARTIN HOLMES, *The Crown Jewels at the Tower of London,* 4th ed. (1974); HUGH TAIT, *The Waddesdon Bequest: The Legacy of Baron Ferdinand Rothschild to the British Museum* (1981); and HUGH TAIT (ed.), *Jewelry, 7000 Years: An International History and Illustrated Survey from the Collections of the British Museum* (1987; also published as *Seven Thousand Years of Jewellery*). (G.Gr.)

Drugs and Drug Action

Drugs are chemical substances that affect the functioning of living things and the organisms (such as bacteria, fungi, and protozoans) that infect them. Pharmacology, the science of drugs, deals with all aspects of drugs in medicine, including their mechanism of action, physical and chemical properties, metabolism, and therapeutics and prophylaxis.

Until the mid-19th century the approach to drug therapeutics was entirely empirical. This thinking changed when the mechanism of drug action began to be analyzed in physiological terms and when some of the first chemical analyses of naturally occurring drugs were performed. The end of the 19th century signaled the growth of the pharmaceutical industry and the production of the first synthetic drugs. Chemical synthesis has become the most important source of therapeutic drugs, although genetic engineering is being developed as a means of synthesizing proteins.

Drugs produce harmful as well as beneficial effects, and decisions about when and how to use them therapeutically always involve the balancing of benefits and risks. Drugs approved for human use are divided into ethical preparations, available only with a prescription, and over-the-counter drugs, which can be bought freely. The availability of drugs for medical use is regulated by law. Details of all approved substances are published in *The United States Dispensatory* and *The National Formulary*. Similar publications exist in other developed countries.

Drug treatment is the most frequently used type of therapeutic intervention in medicine. Its power and versatility derive from the fact that the body relies extensively on chemical communications systems to achieve integrated function among billions of separate cells. The body is, therefore, highly susceptible to the calculated chemical subversion of parts of this communications network that occurs when drugs are administered.

For coverage of related topics in the *Macropædia* and the *Micropædia*, see the *Propædia*, Part Four, Division II, especially Section 424.

This article is divided into the following sections:

General principles

MECHANISM OF DRUG ACTION

With very few exceptions, in order for a drug to affect the function of a cell, an interaction at the molecular level must occur between the drug and some target component of the cell. In most cases the interaction consists of a loose, reversible binding of the drug molecule, although some drugs can form strong chemical bonds with their target sites, resulting in long-lasting effects. Three types of target molecules can be distinguished: (1) receptors; (2) macromolecules that have specific cellular functions, such as enzymes, transport molecules, and nucleic acids; and (3) membrane lipids.

Receptors. Receptors are protein molecules that recognize and respond to the body's own (endogenous) chemical messengers, such as hormones or neurotransmitters. Drug molecules may combine with receptors to initiate a series of physiological and biochemical changes. Receptor-mediated drug effects involve two distinct processes: binding, which is the formation of the drug–receptor complex; and receptor activation, which moderates the effect. Affinity is a term that describes the tendency of a drug to bind to a receptor; efficacy (sometimes called intrinsic activity) describes the ability of the drug–receptor complex to produce a physiological response. Together, the affinity and the efficacy of a drug determine its potency.

Affinity and efficacy

Differences in efficacy determine whether a drug that binds to a receptor is classified as an agonist or as an antagonist. A drug whose efficacy and affinity are suffi-

cient for it to be able to bind to a receptor and affect cell function is said to be an agonist. A drug with the affinity to bind to a receptor but without the efficacy to elicit a response is known as an antagonist because in binding it can block the effect of an agonist.

The binding of a drug to a receptor site requires a precise chemical fit, and a small change in a drug's chemical structure may drastically alter its potency. For example, many drug molecules exist in two forms (called optical isomers), which are identical except that one is a mirror image of the other. One form is usually much more potent than the other, implying that the receptor can distinguish them readily, even though they are chemically almost identical.

The degree of binding can be measured directly by the use of radioactively labeled drugs or inferred indirectly from measurements of the biological effects of agonists and antagonists. Such measurements have shown that the reaction

$$\text{drug} + \text{receptor} \rightleftharpoons \text{drug–receptor complex}$$

generally obeys the law of mass action in its simplest form. Thus, there is a relationship between the concentration of a drug and the amount of drug–receptor complex formed.

The structure–activity relationship describes the connection between chemical structure and biologic effect. Such a relationship explains the efficacies of various drugs and has led to the development of newer drugs with specific mechanisms of action. The contribution of the British pharmacologist Joseph Black to this field led to the development, first, of drugs that selectively block the effects of epinephrine and norepinephrine on the heart (beta blockers, or beta-adrenergic blocking agents) and, second, of drugs that block the effect of histamine on the stomach (H_2-blocking agents), both of which are of major therapeutic importance.

Receptors for many hormones and neurotransmitters have been isolated and biochemically characterized. All of these receptors are proteins, and most are incorporated into the cell membrane in such a way that the binding region faces the exterior of the cell. This allows the endogenous chemicals freer access to the cell. A reconstruction, based on biochemical analysis, on the acetylcholine receptor of muscle is shown in Figure 1. Receptors for steroid hormones (*e.g.*, hydrocortisones and estrogens) differ in being located in the cell nucleus and are accessible only to molecules that can enter the cell across the membrane.

Modified from J. Kistler *et al.*, *Biophysical Journal*, vol. 37, p. 377 (January 1982)

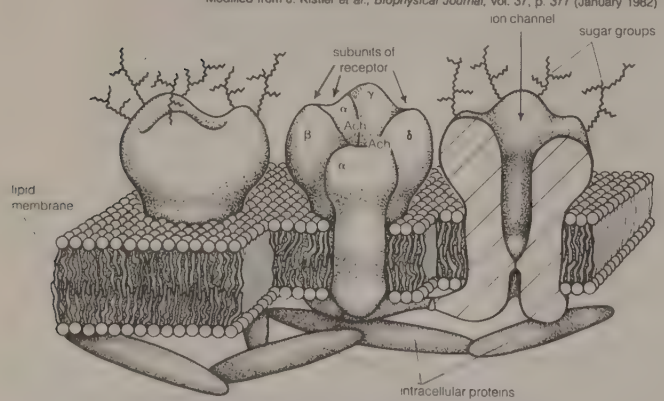

Figure 1: Representation of the acetylcholine receptor, which consists of an aggregate of protein molecules that surrounds a central channel and traverses the lipid layer of the cell membrane.

Receptor-mediated events. Many different kinds of cellular responses may be initiated by receptor activation. For example, nerve cells may be stimulated or inhibited by neurotransmitters acting on surface receptors. In order for the activated receptor to elicit the proper response, certain intermediate processes must take place. Various mechanisms are known to be involved in the processes between receptor activation and the cellular response (also called receptor–effector coupling). Among the most important ones are the following: (1) direct control of ion channels in the cell membrane; (2) regulation of cellular activity by way of intracellular chemical signals, such as cyclic adenosine 3′,5′-monophosphate (cAMP), inositol phosphates, or calcium ions; and (3) regulation of protein synthesis.

Receptor–effector coupling

In type (1) mechanisms, the ion channel is part of the same protein molecule as the receptor, and no biochemical intermediates are involved. Receptor activation briefly opens the transmembrane ion channel, and the resulting flow of sodium and potassium ions across the membrane causes a change in the transmembrane potential of the cell, leading to the initiation or inhibition of electrical impulses. Such mechanisms are common for neurotransmitters that act very rapidly. Examples include the receptors for acetylcholine, which are illustrated in Figure 1, and for other fast excitatory or inhibitory transmitter substances in the nervous system, such as glutamate and glycine.

In type (2) mechanisms, chemical reactions that take place within the cell trigger a series of responses. These mechanisms operate with many hormones and neurotransmitters that act more slowly. The receptor may control calcium influx through the outer cell membrane, thereby altering the concentration of free calcium ions within the cell, or it may control the catalytic activity of one or more membrane-bound enzymes. One of these enzymes is adenylate cyclase, which catalyzes the conversion of adenosine triphosphate (ATP) within the cell to cAMP, which in turn binds to and activates intracellular enzymes that catalyze the attachment of phosphate groups to other functional proteins; these may be involved in a wide variety of intracellular processes, such as muscle contraction, cell division, and membrane permeability to ions. A second receptor-controlled enzyme is phosphodiesterase, which catalyzes the cleavage of a membrane phospholipid, phosphatidylinositol, releasing the intracellular messenger inositol triphosphate. This substance in turn releases calcium from intracellular stores, thus raising the free calcium ion concentration.

Regulation of free calcium ions

Regulation of the concentration of free calcium ions is important because, like cAMP, calcium ions control many cellular functions. An ubiquitous intracellular protein, calmodulin, binds calcium ions, and this complex secondarily controls the activity of various enzymes and other functional proteins.

In type (3) mechanisms, which are peculiar to steroid hormones and related drugs, the steroid–receptor complex acts on specific regions of the genetic material deoxyribonucleic acid (DNA) of the cell nucleus, resulting in the formation of messenger ribonucleic acid (mRNA) that codes for one or more cellular proteins. The effect of the resulting increase in protein synthesis depends on the particular proteins and cell types that are involved. In the uterus, for example, estrogen stimulates the production of structural proteins, leading to growth of the organ. Steroids generally act much more slowly (hours to days) than agents that act by either mechanism (1) or (2).

Desensitization. Most receptor-mediated events show the phenomenon of desensitization, which means that continued or repeated administration of a drug produces a progressively smaller effect. Among the complex mechanisms involved are conversion of the receptors to a refractory (or unresponsive) state in the presence of an agonist, so that activation cannot occur, or the removal of receptors from the cell membrane (down-regulation) after prolonged exposure to an agonist. Desensitization is a reversible process, although it can take hours or days for receptors to recover after down-regulation. The converse process (up-regulation) occurs in some instances when receptor antagonists are administered. These adaptive responses are undoubtedly important when drugs are given over a period of time, and they may account partly for the phenomenon of tolerance (an increase in the dose needed to produce a given effect) that occurs in the therapeutic use of some drugs.

Adaptive responses to drug administration

Functional macromolecules. Many drugs work not by combining with specific receptors but by binding to other proteins, particularly enzymes and transport proteins. For example, physostigmine inhibits the enzyme acetylcholinesterase, which inactivates the physiological transmitter acetylcholine, thereby prolonging and enhancing its

actions; allopurinol inhibits an enzyme that forms uric acid and is used therefore in treating gout. Transport proteins are important in many processes, and they may be targets for drug action. For example, local anesthetics block the conduction of nerve impulses by blocking sodium channels in the nerve membrane, and some antidepressant drugs work by blocking the uptake of norepinephrine or serotonin by nerve terminals. Nucleic acids may also be targets for drug action, as in the case of many anticancer drugs, which prevent cell division by binding to specific regions of DNA.

Membrane lipids. Some drugs produce their effects by chemically nonspecific interaction with membrane lipids. These drugs act nonspecifically in the sense that they affect virtually all cells, irrespective of the presence of any receptor site or other target molecule. Structure–activity relationships within this group show that potency is closely related to lipid solubility and does not depend appreciably on chemical structure. Such chemicals are thought to work by dissolving in the lipid of cell membranes and thus altering their physical properties (*e.g.,* volume and fluidity) in such a way as to affect cellular function. Drugs of this type include volatile anesthetic agents (*e.g.,* halothane) as well as depressants such as ethanol.

Other types of drug action. Certain drugs act without engaging in any direct interaction with the components of the cell. An example is mannitol, an inert polysaccharide that acts purely by its osmotic effect. This drug increases urine production markedly because it interferes osmotically with water reabsorption by the kidney tubule. Another example is magnesium sulfate, which works similarly in the intestine and has a cathartic effect.

FATE OF DRUGS IN THE BODY

Dose–response relationship. The effect produced by a drug varies with the concentration that is present at its site of action and usually approaches a maximum value beyond which a further increase in concentration is no more effective. A useful measure is the median effective dose, ED50, which is defined as the dose producing a response that is 50 percent of the maximum obtainable. ED50 values provide a useful way of comparing the potencies of drugs that produce physiologically similar effects at different concentrations. Sometimes the response is measured in terms of the proportion of individuals in a sample population that show a given all-or-nothing response (*e.g.,* loss of reaction to a painful stimulus or appearance of convulsions) rather than as a continuously graded response; as such, the ED50 represents the dose that causes 50 percent of a sample population to respond. Similar measurements can be used as a rough estimate of drug toxicity, the result being expressed as the median lethal dose (LD50), which is defined as the dose causing mortality in 50 percent of a group of animals.

Median effective dose

When a drug is used therapeutically it is important to understand the margin of safety that exists between the dose needed for the desired effect and the dose that produces unwanted and possibly dangerous side effects. This relationship, termed the therapeutic index, is defined as the ratio LD50:ED50. In general, the narrower this margin, the more likely it is that the drug will produce unwanted effects. The therapeutic index has many limitations, notably the fact that LD50 cannot be measured in humans and when measured in animals is a poor guide to the likelihood of unwanted effects in humans. Nevertheless, the therapeutic index emphasizes the importance of the margin of safety, as distinct from the potency, in determining the usefulness of a drug.

Variability in responses. The response to a given dose of a drug is likely to vary when it is given to different persons or to the same person on different occasions. This is a serious problem, for it can result in a normally effective dose of a drug being ineffective or toxic in other circumstances. Many factors are known to contribute to this variability, with some important ones being age, genetics, absorption, disease states, drug interactions, and drug tolerance.

Adverse effects. No drug is wholly nontoxic or completely safe. Adverse effects can range from minor reactions, such as dizziness or skin reactions, to serious and even fatal effects. Adverse reactions can be divided broadly into effects that result from an exaggeration of the basic action of the drug, which can usually be controlled by reducing the dosage, and effects that are unrelated to the basic action of the drug and occur in only a small proportion of individuals, irrespective of the dose given. Effects of the latter type are known as idiosyncratic effects and include some very severe reactions, such as sudden cardiovascular collapse or irreversible suppression of blood cell production. Many reactions of this type have an allergic basis. Toxic effects of this kind, though rare, are unpredictable and sometimes highly dangerous, and they severely limit the usefulness of many effective drugs. It has been increasingly recognized that drugs can produce other kinds of unwanted effects, such as interference with fetal development (teratogenesis) or long-term genetic damage that may make a person susceptible to the development of cancer.

The sporadic and delayed nature of many adverse drug reactions and the fact that they may not be predictable from animal tests pose serious practical problems. Often such effects are, and indeed can only be, discovered after a drug has been used in humans for some time.

Absorption, distribution, and elimination. In order to produce an effect a drug must reach its target site in adequate concentration. This involves several processes, embraced by the general term pharmacokinetics. In general, the following processes are involved: (1) administration of the drug; (2) absorption from the site of administration into the bloodstream; (3) distribution to other parts of the body, including the target site; (4) metabolic alteration of the drug; (5) excretion of the drug or its metabolites.

An important step in all of these processes is the movement of drug molecules through cellular barriers (*e.g.,* the intestinal wall, the walls of blood vessels, the barrier between the bloodstream and the brain, and the wall of the kidney tubule), which constitute the main restriction to the free dissemination of drug molecules throughout the body. To cross most of these barriers the drug must be able to move through the lipid layer of the cell membrane. Drugs that are highly lipid-soluble do this readily; hence they are rapidly absorbed from the intestine and quickly reach most tissues of the body, including the brain. They readily enter liver cells (one of the main sites of drug metabolism) and are consequently liable to be rapidly metabolized and inactivated. They can also cross the renal tubule easily and thus tend to be reabsorbed into the bloodstream rather than being excreted in the urine.

Lipid solubility

Non-lipid-soluble drugs (*e.g.,* many neuromuscular blocking drugs) behave differently because they cannot easily enter cells. Therefore, they are not absorbed from the intestine and they do not enter the brain. Because they may escape metabolic degradation in the liver, they are excreted unchanged in the urine. Certain of these drugs cross cell membranes, particularly in the liver and kidney, with the help of special transport systems, which can be important factors in determining the rate at which drugs are metabolized and excreted.

Administration. Drugs are given by two general methods: enteral and parenteral administration. Enteral administration involves the esophagus, stomach, and small and large intestines (*i.e.,* the alimentary canal). Methods of administration include oral, sublingual (dissolving the drug under the tongue), and rectal. Parenteral routes, which do not involve the alimentary canal, include intravenous (injection into a vein), subcutaneous (injection under the skin), intramuscular (injection into a muscle), inhalation (infusion through the lungs), and percutaneous (absorption through intact skin).

Enteral and parenteral administration

After oral administration of a drug, absorption into the bloodstream occurs in the stomach and intestine, which usually takes about one to six hours. The rate of absorption depends on factors such as the presence of food in the stomach, the particle size of the drug preparation, and the acidity of intestinal contents. Intravenous administration of a drug can result in effects within a few seconds, making this a useful method for emergency treatment. Serious circulatory and respiratory effects can occur with

this method, however, and great care is necessary. Subcutaneous or intramuscular injection usually produces effects within a few minutes, depending largely on the local blood flow at the site of the injection. Inhalation of volatile or gaseous agents also produces effects in a matter of minutes and is mainly used for anesthetic agents.

Distribution. The bloodstream carries drugs from the site of absorption to the target site and also to sites of metabolism or excretion, such as the liver, kidneys, and, in some cases, the lungs. Many drugs are bound to plasma proteins, and in some cases more than 90 percent of the drug present in the plasma is bound in this way. This bound fraction is inert. Protein binding reduces the overall potency of a drug and provides a reservoir to maintain the level of the active drug in blood plasma. The effects of the drug, therefore, are reduced but prolonged by binding. To pass from the bloodstream to the target site, drug molecules must cross the wall of blood capillaries. This occurs rapidly in most regions of the body. The capillary walls of the brain and spinal cord, however, are relatively impermeable, and in general only drugs that are highly lipid-soluble enter the brain in any appreciable concentration.

Metabolism. In order to alter or stop a drug's biologic activity and prepare it to be eliminated from the body, it must undergo one of many different kinds of chemical transformations. One particularly important site for these actions is the liver. Metabolic reactions in the liver are catalyzed by enzymes located on a system of intracellular membranes known as the endoplasmic reticulum. In most cases the resultant metabolites are less active than the parent drug; however, there are instances where the metabolite is as active as, or even more active than, the parent. In some cases the toxic effects of drugs are produced by metabolites rather than the parent drug.

Role of the liver

Many different kinds of reactions are catalyzed by drug-metabolizing enzymes, including oxidation, reduction, removal of substituent chemical groups, splitting of labile (chemically unstable) bonds, and addition of new substituents. The product is often less lipid-soluble than the parent and is consequently excreted in the urine more rapidly. Many of the causes of variability in drug responses reflect variations in the activity of drug-metabolizing enzymes.

Excretion. The main route of drug excretion is through the kidney; however, volatile and gaseous agents are excreted by the lungs. Small quantities of drugs may pass into sweat, saliva, and human milk, the latter being potentially important in breast-feeding mothers. Although some drugs are excreted mainly unchanged into the urine, most are metabolized first. The first stage in excretion involves passive filtration of plasma through structures in the kidney called glomeruli, through which drug molecules pass freely. The drug thus reaches the renal tubule, where it may be actively or passively reabsorbed, or it may pass through into the urine. Many factors affect the rate of renal excretion of drugs, important ones being binding on plasma proteins (which impedes their passage through the glomerular filter) and urinary acidity, which can affect the rate of passive reabsorption of the drug by altering the state of its ionization.

Time course of drug action. The rise and fall of the concentration of the drug in the blood plasma over time determines the course of action of most drugs. If a drug is given orally, three phases can be distinguished: the absorption phase, leading to a peak in plasma concentration; the redistribution phase, when the plasma concentration falls rapidly as the drug is taken up by various tissues; and the elimination phase, a slower phase of decline as the drug is metabolized or excreted (see Figure 2).

Phases in drug concentration

For therapeutic purposes it is often necessary to maintain the plasma concentration within certain limits over a period of time. If the plasma half-life ($t_{1/2}$; the time it takes for the plasma concentration to fall to 50 percent of its starting value) is long, doses can be given at relatively long intervals (*e.g.*, once per day), but if the $t_{1/2}$ is short (less than about 24 hours) more frequent doses are necessary. If a drug with a long half-life is given in intervals over the course of several days, there is a risk that a gradual rise of the concentration of the drug in the plasma will result in toxicity and unwanted side effects.

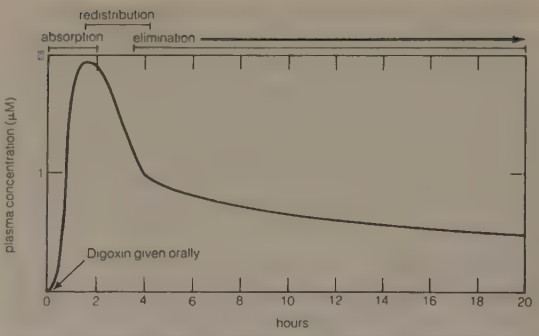

Figure 2: Typical course of changes in the plasma concentration of a drug over time after oral administration.

Types of drugs

AUTONOMIC NERVOUS SYSTEM PHARMACOLOGY

The nervous system of vertebrates comprises two main divisions: the central nervous system, which includes the brain and spinal cord; and the peripheral nervous system, which can be further divided into the somatic nervous system, whose main function is to innervate body structures (*e.g.*, most skeletal muscles) under conscious, voluntary control, and the autonomic nervous system, which is concerned with the involuntary processes of the body's glands, large internal organs, cardiac muscle, and blood vessels. The autonomic nervous system consists of the sympathetic and the parasympathetic systems, which are distinct both functionally and anatomically.

The sympathetic system initiates a series of reactions, called "fight-or-flight" reactions, that prepare the body for activity. The heart rate increases, blood pressure rises, and breathing quickens. The amount of glucose in the blood rises, providing a reservoir of quick energy. The flow of blood to the skin and body organs decreases, allowing more blood to flow to the heart and muscles. The parasympathetic system generally functions in an opposite way, initiating responses associated with rest and energy conservation; its activation causes breathing to slow, salivation to increase, and the body to prepare for digestion. This picture is, however, a considerable oversimplification. The autonomic nervous system as a whole exerts a continuous, local control over the function of many organs (such as the eye, lung, urinary bladder, and genitalia), regardless of whether the body is preparing to react or to rest. The main physiological actions produced by the autonomic nervous system are shown in Table 1.

Table 1: Important Physiological Effects Mediated by the Autonomic Nervous System

organ	response		
	sympathetic activity	receptor type	parasympathetic activity
eye	pupil dilation	α_1	pupil constriction
heart	increase in rate, force, and ectopic beats	β_1	decrease in rate and force
blood vessels	constriction (most)	α_1	dilation (few)
	dilation (some)	β_2	
bronchi	dilation	β_2	constriction
	secretion inhibited		secretion
gut	reduced motility and secretion	α_1, α_2, β_2	increased motility and secretion
bladder	relaxation	β_2	contraction
uterus	relaxation	β_2	contraction
skeletal muscle	glycogen breakdown	β_2	contraction
liver	glycogen breakdown	β_2	--

Control by the autonomic nervous system

The autonomic nervous system exerts its control through a network of nerve fibres that originate from the cells in the spinal cord. Each of these neurons ends by forming a junction with a second neuron, often called a ganglion cell because in some cases these second neurons are grouped together in swellings called ganglia. The first neuron is

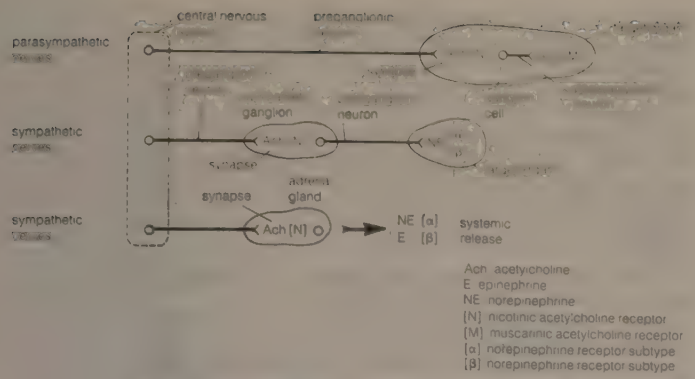

Figure 3: Organization of the autonomic nervous system.

therefore called preganglionic and the second, postganglionic. The junction between the preganglionic and postganglionic neurons is called a synapse. As the electrical nerve impulse reaches the end of the preganglionic neuron, it causes the release of a chemical substance called a neurotransmitter. There is no direct contact between the two neurons. The neurotransmitter diffuses across the gap between them and acts on the postganglionic neuron by initiating in it a further electrical impulse. Postganglionic neurons innervate the target organs and elicit responses in them once again by inducing a neurotransmitter.

Mechanism of action. The discovery of chemical transmitters (neurotransmitters) was an important event in pharmacological history. While a student at Cambridge in 1904, T.R. Elliott found that the effects of stimulating sympathetic nerves closely resembled the effects of injecting chemical substances obtained from the adrenal gland. He suggested that the sympathetic nerves produced their effects by releasing a substance mimicking the action of epinephrine (adrenaline).

The work of Henry Dale, a British physiologist working in London in 1914, suggested that acetylcholine was the neurotransmitter at the synapse between preganglionic and postganglionic sympathetic neurons and also at the ends of postganglionic parasympathetic nerves. He showed that acetylcholine could produce many of the same effects as direct stimulation of parasympathetic nerves. Firm evidence that acetylcholine was in fact the neurotransmitter came in 1921, when the German physiologist Otto Loewi discovered that stimulation of the autonomic nerves to the heart of a frog caused the release of a substance, later identified to be acetylcholine, which slowed the beat of a second heart perfused with fluid from the first. Similar direct evidence of the release of a sympathetic neurotransmitter, later shown to be norepinephrine (noradrenaline), was obtained by Walter Cannon at Harvard also in 1921.

Classification of nerve fibres

In the autonomic nervous system, nerve fibres are classified on the basis of the neurotransmitter released at the synapse. Nerve fibres that release the neurotransmitter acetylcholine are termed cholinergic fibres; nerve fibres that release the neurotransmitter norepinephrine are termed adrenergic fibres. Cholinergic fibres comprise the axons of the preganglionic sympathetic and both the preganglionic and the postganglionic parasympathetic neurons. The axons of the postganglionic sympathetic neurons are generally autonomic adrenergic fibres. The scheme in Figure 3 is complicated by the fact that these neurotransmitters are now known to have a negative feedback effect in inhibiting their own further release. They do this by combining with presynaptic receptors on the nerve terminals as well as with the postsynaptic receptors on the target organs.

Both acetylcholine and norepinephrine act on more than one type of receptor. Dale found that two foreign substances, nicotine and muscarine, could each mimic some, but not all, of the parasympathetic effects of acetylcholine. Nicotine stimulates skeletal muscle and sympathetic ganglia cells. Muscarine, however, stimulates receptor sites located only at the junction between postganglionic parasympathetic neurons and the target organ. Muscarine slows the heart, increases the secretion of body fluids, and prepares the body for digestion. Dale therefore classified the many actions of acetylcholine into nicotinic effects and muscarinic effects. It has subsequently become clear that there are two distinct types of acetylcholine receptors affected by either muscarine or nicotine.

A similar analysis of the sympathetic effects of norepinephrine, epinephrine, and related drugs was carried out by an American pharmacologist, Raymond Ahlquist, who suggested that these agents acted on two principal receptors. A receptor that is activated by the neurotransmitter released by an adrenergic neuron is said to be adrenoceptive or to be an adrenoceptor. Ahlquist termed the two kinds of adrenoceptor alpha (α) and beta (β). This theory was confirmed when Joseph Black developed a new type of drug that was selective for the β-adrenoceptor.

Both α-adrenoceptors and β-adrenoceptors are divided into subclasses: α_1 and α_2; β_1 and β_2 (Table 1). These receptor subtypes were recognized by their responses to specific agonists and antagonists. Once recognized, they provide important leads in developing new drugs with high activity of a certain kind. For example, salbutamol was discovered as a specific β_2-adrenoceptor agonist. It is used to treat asthma and is a great improvement over its predecessor, isoproterenol; because the activity of isoproterenol is not specific, it acts on β_1-adrenoceptors as well as β_2-adrenoceptors, resulting in cardiac effects that are unwanted and sometimes dangerous.

A complex relationship exists between function and receptor type for α-adrenoceptors and β-adrenoceptors. Alpha$_1$-adrenoceptors usually mediate smooth muscle contraction, particularly the constriction of the blood vessels (vasoconstriction) that results from a buildup of calcium ions within the cell. Alpha$_2$-adrenoceptors are located primarily on nerve terminals, where they act to inhibit the release of the neurotransmitter. Beta$_1$-adrenoceptors are found in the heart and increase the force and rate of the heart's action: β_2-adrenoceptors are primarily found in smooth muscle and produce relaxation. Beta-adrenoceptors of both types are involved in the metabolic effects of epinephrine and norepinephrine on liver, fat, and muscle cells, which convert energy stores to freely usable metabolic fuels. The receptor specificity of various agonists and antagonists is summarized in Table 2.

Table 2: Drugs Acting on Cholinergic and Adrenergic Receptors

	agonists	receptor type*	antagonists	receptor type*
cholinergic	acetylcholine	M, N	tubocurarine	N (skel. muscle)
	nicotine	N (mainly ganglia)	hexamethonium	N (ganglia)
	succinylcholine	N (skel. muscle)	trimethaphan	N (ganglia)
			atropine	M
	muscarinic	M	scopolamine	M
	bethanechol	M	homatropine	M
	pilocarpine	M	cyclopentolate	M
adrenergic	norepinephrine	α_1, α_2, β_1	phentolamine	α_1, α_2
	epinephrine	α_1, α_2, β_2	phenoxybenzamine	α_1, α_2
	isoprenaline	β_1, β_2	yohimbine	α_2
	phenylephrine	α_1	prazosin	α_1
			propranolol	β_1, β_2
	salbutamol	β_2	atenolol	β_1
	clonidine	α_2	butoxamine	β_2
			labetalol	α_1, β_1, β_2

* N = nicotinic acetylcholine receptor, M = muscarinic acetylcholine receptor, α_1, α_2, β_1, β_2 = adrenoceptor subtypes.

Other neurotransmitters

It is now known that acetylcholine and norepinephrine are not the only neurotransmitters. There is strong evidence that adenosine triphosphate (ATP), a substance of special importance as a metabolic energy source within cells, also functions as a neurotransmitter in postganglionic autonomic nerves, and it probably mediates some responses (*e.g.*, bladder contraction and vasoconstriction) previously ascribed to acetylcholine and norepinephrine. Dopamine, known to be a metabolic precursor of norepinephrine, is also thought to mediate vasodilator responses in some organs, especially the kidney. A wide variety of peptides, such as substance P, vasoactive intestinal polypeptide, and cholecystokinin, all of which exert powerful effects on target organs, have been detected in autonomic neurons, and it is likely that these also function as neurotransmitters.

Sites of action. Chemical transmission of nerve impulses in the autonomic nervous system involves several steps, some of which are susceptible to interference by drugs: (1) synthesis of the neurotransmitter from simple chemical compounds; (2) storage of the neurotransmitter in a releasable form (generally believed to be in vesicles within nerve terminals); (3) release of the neurotransmitter, which normally occurs when the nerve terminal is invaded by an electrical impulse in the neuron; (4) feedback action of the neurotransmitter on receptors regulating the release of the neurotransmitter; and (5) dissipation of released neurotransmitter by enzymic breakdown or reuptake into nerve terminals. These steps can be used as a basis for describing the effects of drugs on cholinergic and adrenergic transmission.

The ways in which drugs can interfere with cholinergic transmission of nerve impulses are outlined below.

Step 1. Acetylcholine is made from its precursor, choline, which is actively taken up from the blood by cholinergic nerve terminals where an enzyme, choline acetyltransferase, adds an acetyl group to the choline molecule. The uptake of choline can be inhibited by hemicholinium, a substance that blocks all types of cholinergic transmissions. Because of its lack of selectivity, hemicholinium is of no therapeutic value.

Step 2. Acetylcholine storage is not known to be susceptible to control by drugs.

Step 3. Acetylcholine release by nerve impulses can be blocked by botulinum toxin. This very potent toxin is produced in food that is contaminated by the bacteria concerned and is an occasional cause of severe food poisoning. The most serious effect is paralysis of the skeletal muscle, including the respiratory muscle, but it also paralyzes the whole of the autonomic nervous system.

Step 4. There are many drugs that interact with acetylcholine receptors (Table 2). Acetylcholine itself produces extremely short-lived effects because it is rapidly destroyed in the blood. The only acetylcholine-like drug that is employed therapeutically is pilocarpine, a selective muscarinic receptor agonist, which is used in eyedrops to constrict the pupil and to decrease the intraocular pressure that is raised in the disease glaucoma. Nicotine, a constituent of tobacco smoke, stimulates autonomic ganglia but has no therapeutic value.

Antagonists of muscarinic receptors

Antagonists acting on muscarinic receptors include such drugs as atropine and scopolamine. These drugs suppress all of the actions of the parasympathetic system, resulting in drying up of the secretions of the body (*e.g.*, saliva, tears, sweat, bronchial secretions, and gastrointestinal secretions); relaxation of the smooth muscle in the intestine, bronchi, and urinary bladder; an increase in the heart rate; dilation of the pupil; and paralysis of ocular focusing. These drugs are widely used, first to dry up secretions and dilate the bronchi during anesthesia, and second to dilate the pupil during ophthalmological procedures. Scopolamine is also used to treat seasickness, an effect that depends on its ability to depress the activity of the central nervous system.

Nicotinic receptor antagonists are divided into those that act mainly on skeletal muscle and those that act on ganglia cells. The latter group includes hexamethonium and trimethaphan. These drugs cause overall paralysis of the autonomic nervous system because they do not distinguish between sympathetic and parasympathetic ganglia and therefore are not specific in their action. They were the first effective agents to reduce high blood pressure (antihypertensive drugs), but they have a great many troublesome side effects associated with paralysis of the autonomic nervous system (blurred vision, constipation, impotence, inability to urinate). They have been replaced by more selective drugs (see below *Cardiovascular system pharmacology*).

Step 5. Acetylcholine is inactivated by the enzyme acetylcholinesterase, which is located at cholinergic synapses and breaks down the acetylcholine molecule into choline and acetate. Anticholinesterases are drugs that inhibit the activity of this enzyme, thereby greatly enhancing the action of the neurotransmitter. Drugs in this group include neostigmine, Dyflos, and echothiophate. Their main effects are on skeletal muscle and on the parasympathetic system. Because anticholinesterases inhibit the breakdown of acetylcholine, their effects are caused by the prolonged and exaggerated action of excess levels of acetylcholine on muscarinic receptors. These effects include cardiac slowing, excessive secretions, and strong contractions of the smooth muscle of the bronchi, intestine, and urinary bladder. These drugs are used for their effects on skeletal muscle and the eye (pupillary constriction and decreased intraocular pressure) and for the treatment of atropine poisoning.

The ways in which drugs can interfere with adrenergic transmission of nerve impulses are outlined below.

Step 1. Norepinephrine synthesis starts with the amino acid tyrosine and proceeds via a series of enzymic reactions. A further enzymic step occurs in the adrenal gland, where norepinephrine is converted to epinephrine, both of which are released into the bloodstream. Several drugs are known to inhibit one or more of the steps in the synthesis of norepinephrine, but they are not used therapeutically.

Methyldopa affects the synthesis of norepinephrine by causing adrenergic neurons to make and release a false neurotransmitter, methylnorepinephrine, which is less effective than norepinephrine itself. Methyldopa is used in the treatment of high blood pressure and appears to act by affecting parts of the brain that are involved in the regulation of blood pressure and by acting on peripheral adrenergic nerves.

Step 2. The packaging of norepinephrine into vesicles is prevented by reserspine, an alkaloid obtained from the plant *Rauwolfia*. Because of its many side effects, this drug is now largely obsolete.

Step 3. The release of norepinephrine can be evoked or inhibited by the actions of drugs. Drugs that evoke it produce effects resembling those of sympathetic nerve activity and are termed sympathomimetic agents. They include amphetamine and ephedrine, which act indirectly, mainly by expelling norepinephrine from its storage area in nerve terminals. They cause an increase in the heart rate (sometimes leading to dysrhythmias, or irregular heartbeats) and other sympathetic effects. Ephedrine is occasionally used to dilate the bronchi in treating asthma. Amphetamine-like drugs also have strong effects on the brain, causing feelings of excitement and euphoria, as well as a reduction of appetite, which has led to their use in treating obesity. Their effects on the brain have led to their recreational use and to their use as agents to enhance athletic performance. These drugs are liable to cause addiction, and overdosage may have dangerous cardiovascular and mental effects. There is little need for the therapeutic use of the various amphetamines.

Sympathomimetic agents

Step 4. Drugs that act as agonists or antagonists to adrenoceptors are listed in Table 2. Alpha$_2$-adrenoceptor antagonists are important because they block the ability of norepinephrine to constrict the blood vessels (vasoconstriction). Since most blood vessels are subject to the continuous vasoconstrictor influence of sympathetic nerves, blocking these receptors causes a widespread relaxation of the blood vessels (vasodilation). These drugs are sometimes used to treat high blood pressure (hypertension) and cardiac failure (see below *Cardiovascular system pharmacology*).

Beta-adrenoceptor agonists are extremely useful in treating various kinds of cardiovascular diseases, particularly hypertension, dysrhythmias, and angina. The effect is usually achieved by the β_1-adrenoceptor; however, most of the available drugs also block the β_2-adrenoceptor. This gives rise to various unwanted side effects, such as constriction of the bronchial smooth muscle, which can be dangerous to asthmatic patients, and constriction of certain blood vessels, which may cause patients to complain of cold hands and feet. Beta-adrenoceptor antagonists are also useful in controlling muscle tremors and other symptoms of nervousness or anxiety that result from overactivity of the sympathetic system.
